RESULTS: The average age of the participants was 29.3 and 69% of these were women. 90.2% of the participants reported that training in practice was necessary, however only 67.8% of the participants stated that there should be 6-12 months training period in family practice, 78.6% that the practice should be within walking distance or 30 minutes away by public transport to the hospitals and 74.1% that the patient lists should include people from different socioeconomic levels. The ratio of participants reported that the faculty members and trainers should be in the training practice as consultants were 65.2% and 73.2% in order. 44.6% of the participants thought that trainees and all trainers should be responsible in chain if a malpractice exists. 69.6% of the participants stated that the number and variety of patients should be considered for evaluation of the trainees. While 46.4% of the trainees thought the number of patients in their lists should be between 1001 to 2000.

CONCLUSION: Residents know the importance of training in practice, but there is different between their expectations and official regulations.

Keywords: resident, training in practice, education

Determination Of The Effect Of Thalassemia Training Programs On Educational Level Of Thalassemia Traits

Hamit Sırrı Ketten¹, Medine Çitil², Yeşim Can Çelik³, Oğuz Işık⁴

¹Department of Family Medicine, Kurtul Family Health Center, Kahramanmaraş, Turkey

²Department of Family Medicine, Public Health Center, Kahramanmaraş, Turkey

³Department of Biochemistry, Public Health Laboratory, Kahramanmaraş, Turkey

⁴Department of Family Medicine, Medical Faculty, Kahramanmaraş Sutcu Imam University, Kahramanmaraş, Turkey

BACKGROUND: The aim of this study is to determine the effect of thalassemia training programs on educational level of thalassemia traits.

METHOD: In this study, 67 individuals that have been diagnosed as thalassemia traits in their premarital hemoglobinopathy screening between July 2014 and February 2015 in Kahramanmaraş Mother and Child Care and Family Planning Center, were enrolled. Ten knowledge questions about thalassemia were addressed to participants prior to the training. Each question was scored with one point and the educational level was evaluated on 10 points. Then individuals were given a training program of 15 minutes, and the items were requestioned.

RESULTS: Forty two (62.7%) of participants were male, 25 (37.3%) were female, and the mean age was 26.01±5.80 (min=18, max=50). Thirty four (50.7%) participants stated that they had heard about thalassemia disease before, while 33 (49.3%) participants stated they did not. Mean score of the survey before the training program was 3.52±3.23, and the mean score of the test after training was 8.80±1.52. We found that educational level of participants increased significantly after the training (p=0000). In our study, mean score of women before the training was 3.32±3.00, and the score of men was 3.64±3.39. Educational levels of men and women were

similar ($p=0.696$). We found that the mean score of individuals that were high school graduates or below was 3.26 ± 3.44 , and the mean score of individuals that were university graduates or above was 3.15 ± 3.04 . Educational levels of high school graduates or below and university graduates or above were similar ($p=0.912$).

CONCLUSION: We determined that thalassemia traits seriously lacked information about thalassemia. Furthermore, we detected that the training program about thalassemia increased their educational level significantly.

« Being young, getting old » the role of family physicians throughout the years

Monique Aubart Schuller

SSLMG- Société Scientifique Luxembourgeoise de Médecine Générale

1. Background and AIM:

Trying to stay young is a very popular aim in our society, whereas age, illness and disability often are avoided in public discussions. While life expectancy constantly grows, our fear of ageing, getting dependent and dying grows too.

What's the role of the GP in our ageing society? Do we need special skills to counsel our ageing patients (while we're getting older with them)? How do we GPs face anti-ageing medicine?

2. METHOD:

literature research and statements of patients

3. RESULTS:

A great variety of anti-ageing products already exists and is largely sold i.e. vitamins, resveratrol, omega acids etc. Other methods like stem cell therapy, nanotechnology or cloning promise life extension, sometimes with the hope of overcoming death.

Talking to our elderly patients their opinion often contrasts anti-ageing movement.

4. CONCLUSIONS:

Flexibility is one of the keys for well-ageing, accepting changes in life, adapting to different phases of development are elementary if we want to pass different stages in our lives without bigger problems. The role of GPs gets more and more important, the number of older patients grows throughout our careers. Good skills in communication, geriatrics, and palliative care are beneficial while sometimes simply listening to our elderly patients and spending enough time with them can be the best for them and very enriching for us.

Keywords: ageing, flexibility, longevity

Resident Physician's Empathy Levels and Related Factors

Ceren Karaman Kenesari¹, Nilgün Özçakar², Mehtap Kartal³, Zafer Şişli⁴

¹ceren KARAMAN KENESARI, Dokuz Eylül Üniversitesi, İzmir, Türkiye

²Nilgin ÖZÇAKAR, Dokuz Eylül Üniversitesi, İzmir, Türkiye

³Mehtap Kartal, Dokuz Eylül Üniversitesi, İzmir, Türkiye

⁴Zafer Şişli, Dokuz Eylül Üniversitesi, İzmir, Türkiye

Background & AIM:

Empathy is reflecting one's inner feelings to an object or event, and the ability to experience one's feelings and thoughts matching another person's. Physicians, while treating the diseases, have to remember their patients are human beings and create empathy with them. Empathy of the physician increases patients' satisfaction and has a positive impact on the patient's health status and leads physicians to show more ethical approach and more effective and accurate diagnosis. It's aimed to investigate empathy levels of residents and related factors.

METHOD:

The study was completed by 306 residents in Internal and Surgical Sciences Departments of Dokuz Eylul University Medical Faculty. Questionnaires including sociodemographic characteristics and Jefferson Scale of Physician Empathy (JSPE) and Swedish Demand Control Support Questionnaire were administered. Student's t test, ANOVA were used and $p < 0.05$ was considered as statistically significant.

RESULTS:

The response rate was 60.5%, 52.9% were female. Mean age was 28.9 ± 2.9 , 63.4% ($n=194$) were in Internal Sciences Departments and 82.7% ($n=253$) were in specialties they wished. Total mean score of JSPE was 67.1 ± 9.8 (43-100). Swedish Demand Control Support Questionnaire total mean score was 67.3 ± 7.6 (42-85). Subscale mean scores were for workload 14.9 ± 2.5 (7-20), job control 18.8 ± 2.9 (8-26) and social support 17.3 ± 3.8 (6-24).

There was no difference in empathy scores by gender, women defined their workloads lower ($p=0.002$). Empathy levels decreases with seniority but not significant ($p=0.335$). Empathy scores of internal science residents, is higher, but not significant ($p=0.822$). Surgical resident's workload scores (16.1 ± 1.5) was higher than internal medicine (14.2 ± 2.6) ($p < 0.001$).

CONCLUSIONS:

Monotonousness, job stress and burnout can occur due to working conditions of residents'. Eventually they can start seeing patient as an object related to job and forget the patient is a human being with feelings. No matter what residency they work, residents have to be aware of empathy and its power.

Problem with care of the patients with special needs

Nevenka Strahinja Radosavljevic

Prim dr Nevenka Radosavljevic

Background & Aim

Overview of challenges and problems with care patients with special needs of cardio vascular diseases - A case report

Method

Through the specific case report

PATIENT M.L. birth 1949 born without abnormalities as a child of 7 months had chickenpox, as a complication got encephalitis that left permanent consequences.

His sister takes care of him and he is not placed in institutions.

He is feeding himself, but he is suspicious of an unknown person and then he becomes aggressive and agitated.

He had been treated from hypertension fully 20 years.

In December 2010 the doctor was invited on a home visit because patient had difficulty breathing, rapid, shallow breathing, coughing, had a stomach ache followed by general weakness and sweating.

FINDINGS: Pale, afraid and very sweaty.

PULMO; small respiratory noises, bilaterally weakened diffusely respiration

Cor: Cardiac function rhythmic, tone quieter, there is no noise

EKG: sinus rhythm, QS in V2- V5, abridged T in D1, biphasic in AVL, V2, V3 shallow negative in V 4-V6

DG AIM ANTEROLATERALIS

Oedema pulmonum

Retardatio Mentalis

And send to hospital for P.C.I.

The Patient needed hospitalization, but patient was very upset, not able to stay because there were no possibilities for the family members to stay with him.

Institution has no conditions for treatment of patients with special needs so the patient was sent home with oral treatment – medication (Monizol, Aspirin, Plavix, Lasix, Ramipril, Amlopin) Patient is well-tolerated therapy in a home environment and his condition is stable with occasional medical control at home.

Conclusion

For treatment of patients with special needs it is necessary to prepare special part of the Cardiology Hospital department with a multidisciplinary approach Psychiatric and family members.

Recording the reasons the immigrants attend the health center in a rural area of Crete

Theodoros Vasilopoulos¹, Georgia Arseni², Nikolaos Kontarakis¹, Ioannis Poulorinakis¹, Evangelia Giannopoulou¹, Aikaterini Chourdaki¹, Eirini Tsimplostefanaki¹

¹Health center of Ag.Barbara, Herakleio,Crete, Greece

²Venizeleio Gen. Hospital, Herakleio,Crete,Greece

BACKGROUND-AIM: According to the results of the population Census in 2011, the settlers in our country the year before, who had not greek nationality were 45.803 (57.6%),concerning mainly economic migrants.

The purpose of this study is to document the most common causes and symptoms with which foreign migrants present in primary health care in a rural area of Heraklion, Crete.

METHODS: The data was retrospectively drawn from the attendance records of the first quarter of 2014, where 95 foreign visits were recorded. Of these, 43 (45.26%) were male and 52 (54.74%) female. The nationalities were 46 (48.42%) Albanian, 29 (30.35%), Bulgarian, 11 (11.58%) Romanian, 7 (7.37%) Pakistani and two Indian.

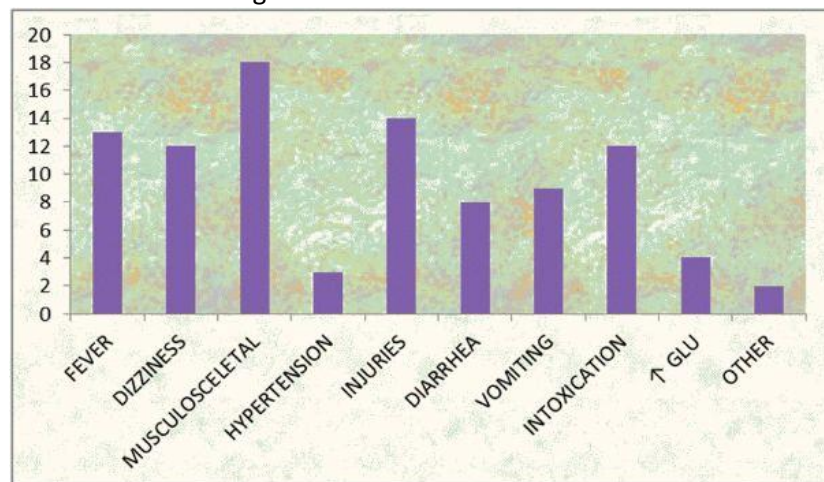

Concerning the age: 10 foreigners (1-10 y.o), 13 (11-20 y.o), 7 (21-30 y.o), 5 (31-40 y.o), 31 (41-50 y.o), 29 (51-60 y.o). Only 21 had personal health book. The rest (77.89%) either did not have health booklet or they used others' booklets, such as their employers, which questions the history of the disease and chronic medication of patients.

RESULTS: The results concerning the reasons of the immigrants attendance (Figure1)

CONCLUSIONS: The majority of immigrants (93.6%) are employed in agriculture and animal husbandry, accounting for musculoskeletal injuries and trauma. Symptoms such as dizziness and headache are justified by their long exposure to the weather, the nature of work itself (hard manual labor) and the irregular sometimes food and water habits (for example due to religious particularities). Special mention should be made about the living conditions, since their financial malaise deprives them from a good standard of living. Immigrants are considered a vulnerable population group. Therefore, it is necessary to record their profile and medical history, providing them with a more comprehensive medical approach on behalf of the general practitioners, in cooperation with other social and state structures, with respect to their cultural particularities.

Adolescent pregnancy: a bump into culture or culturally accepted?

Joana Oliveira Baptista¹, Rute Nascimento Marques², Sara Conceição Cunha³

¹Health Unit Santa Joana, Aveiro, Portugal

²Health Unit S. Miguel, Vila Nova Gaia, Portugal

³Health Unit Oceanos, Matosinhos, Portugal

Background & AIM: Teen pregnancy is considered to be a health problem and it is known that adolescent parents and their children represent high-risk populations. Nowadays, physicians are increasingly confronted with patients from various ethnic backgrounds. In addition to language proficiency, cultural differences of minority groups play an important role in interethnic encounters, changing the definition of “normality” and expected behaviours. In contact with patients from different cultures, the physician’s reference cultural background is missing and differences in views can be magnified, leading to increased communication difficulties.

METHODS: A case report based on patient interview and electronic clinical records. A bibliographical research was conducted for clinical review.

RESULTS: Sixteen year old gypsy adolescent. Personal history of menarche at 11 years old, and married at 12. In October 2012, with 13 years of age, consults the family doctor for 3 months amenorrhea and a vaginal ultrasound revealed “single foetus with 10 weeks of evolution” - an unplanned pregnancy but desired by the couple. The second trimester obstetric ultrasound detected a congenital malformation of the foetus that led to a medical interruption of pregnancy.

In an attempt to prevent another unplanned pregnancy, it was proposed in a family planning consultation a subcutaneous implant that she refused due to the desire to be pregnant again.

In September 2013 she comes to a medical appointment with a twin pregnancy of 13 weeks of evolution. The twin female new-borns were born by eutocic delivery in February 2014.

CONCLUSION: Behaviours and attitudes towards pregnancy are highly influenced by culture. While maternal age tends to increase in most cultures, the gypsy culture supports teen pregnancy. Although physicians do perceive cultural differences they should try to adapt their communication accordingly. However it is hard to deal with all the challenges posed to doctors during the medical consultation.

Twelve Communication Barriers and Family Medicine Applications

Nurdan Kırımlıoğlu¹, İlhami Ünlüoğlu²

¹Eskisehir Osmangazi University Faculty of Medicine Dep of History of Medicine and Medical Ethics Eskisehir /Turkey

²Eskisehir Osmangazi University Faculty of Medicine Dep of of Family Medicine Eskisehir /Turkey

Family Medicine, one of the important requirements in the field of public health is important for physician-patient communication.

Physician-patient communication is a interaction process of both sides. Impressions gained during interviews in this process are the basis for important and clinical applications in terms of definition and solution of the problem. Therefore, verbal and nonverbal communication environments where patient can make case must be created entirely.

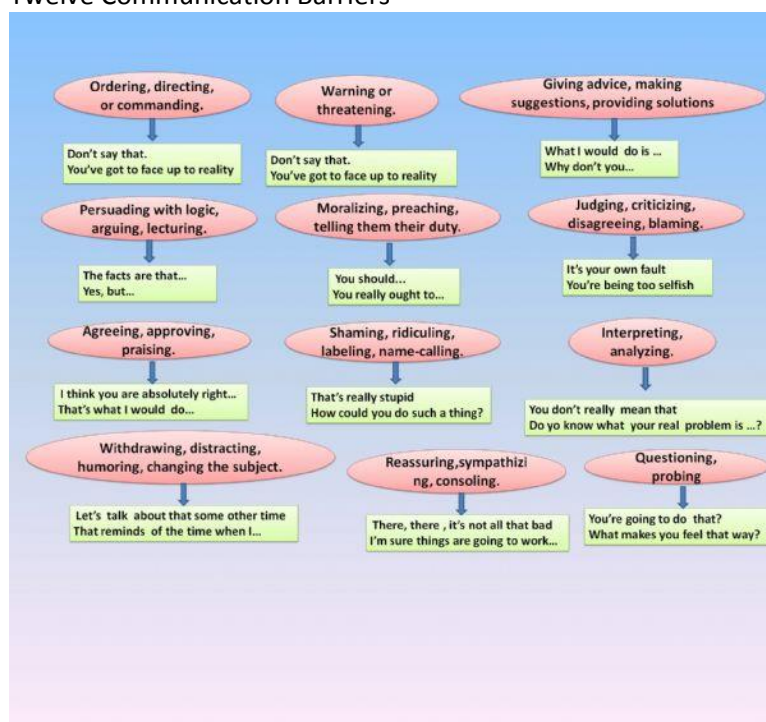

It is known that clear and effective communication cannot take place between the doctor and patient and that there are some problems. Communication action may not always be in the format as desired by the doctor. The expectations or thoughts on communication with their doctor of patients having different ideas about how they would be affected by health problems may also vary. A part of communication problems in doctor-patient or patient-other health care professional relationship can be said as resulting from the language of patient and doctor, and different use of language.

The language barriers influencing negatively the effective participation of patients in communication with doctors and other health care professionals and defined as "twelve communication barriers" in the literature and their reflection on family medicine practice will be presented in this study.

The communication between the patient and the family physician should be strong and free of obstacles in order to protect and develop the health in first step health care services and to present the intended holistic approach. Problems which possible to arise when the Patient and physician-induced barriers are supported by a empathic approach including many communication skills such as speaking, using the body language, listening will be minimized.

Spirometric Measurements on World COPD Day

Özlem Şengören Dikiş¹, Seyhan Us Dülger¹, Hakan Demirci²

¹Department of Pulmonary Medicine, Sevket Yilmaz Training and Research Hospital, Bursa, Turkey

²Department of Family Medicine, Sevket Yilmaz Training and Research Hospital, Bursa, Turkey

AIM: We organized a 'World Chronic Obstructive Pulmonary Disease (COPD) Day' event to raise awareness in society of the disease and we evaluated the results of the activity.

MATERIALS-METHODS: Volunteers (n = 79) consisted of persons shopping in a famous shopping center in Bursa. A short past history of COPD from the volunteers was requested. Pulmonary Function Tests were performed by spirometry and a Fagerstrom test for dependence was filled out by the volunteers. In cases where airway obstruction was detected, physicians performed a reversibility test with the patients.

RESULTS: Of the 79 volunteers who participated in the study, 39 cases were detected to have airway obstruction. Of these, 15 patients had been previously diagnosed as having COPD but 24 patients were diagnosed with COPD for the first time. There was no newly diagnosed COPD patient among nonsmokers. The prevalence of COPD was 49.36% and the awareness rate was only 38.46%.

CONCLUSIONS: In the present study, we determined the COPD prevalence to be 49.36%, which is quite high compared to previous studies published in Turkey. In such a cross sectional study, volunteers would probably be composed of persons who would have the disease at higher rates. We observed that there was a low awareness of COPD among smokers. Events aiming to increase social awareness to such a particularly prevalent disease should be encouraged.

Keywords: COPD, awareness, smoking, reversibility

Do we count sheep properly? A study on insomnia at a Primary Health Center

Maria Jose Agueros Fernandez¹, Patricia Noemi Aguilera Samaniego², Alvaro Perez Martin², Montserrat Gago Bustamante², Jose Ramon Lopez Lanza², Victor Ovejero Gomez⁴, Alfredo Avellaneda Fernandez³, Cecilia Traspuesto Pascual², Isabel Muñoz Franco², Maria Antonia Gandara Revuelta¹, Begoña Bermejo Garcia¹, Antonio Alonso Gonzalez²

¹Primary Health Center Zapaton. Torrelavega. Spain

²Primary Health Center Centro. Santander. Spain

³Primary Health Center Los Carmenes. Madrid. Spain

⁴Sierrallana Hospital. Torrelavega. Spain

Background & AIM: To study the characteristics of the treatment of insomnia carried out in an urban Primary Health Center.

METHOD: A transversal descriptive study of all the cases of insomnia in an urban medical centre in Santander, with a population of 19,540 inhabitants, over 2013. For quantitative variables, the study used the average and the typical deviation (in the case of normal distribution). For qualitative variables, percentages are used.

RESULTS: 161 subjects were studied. The average age was 64.34 years old (SD±17.48), predominantly female (70.4%). 97.5% received pharmacological treatment after the first consultation, mainly zolpidem (36.2%), lorazepam (22.2%), lormetazepam (16.9%), brotizolam (7.7%), bromazepam (3.9%), ketazolam (3.4%), trazodone (2.9%). The treatment was considered to be effective in 75.2% of the cases, and in 2.5% of the cases, side effects were observed, meaning the drug was withdrawn. The information sheet on advice on insomnia was given to 8% of the cases.

CONCLUSIONS: The typical profile is that of a woman of around 65 years of age. This problem often results in the prescribing of medicines, however, the information sheet, which could be useful, was given out to only a few. Zolpidem and lorazepam are the most prescribed active ingredients. There are very few side effects which mean the drug has to be withdrawn

Screening test for prevention of osteoporosis

Enisa Ramic¹, Esad Alibasic², Amila Bajraktarevic¹, Enisa Karic¹, Olivera Batic Mujanovic¹, Izudin Zahirovic³

¹Primary Health Care Center Tuzla

²Primary Health Care Center kalesija

³Primary Health Care Center Srebrenik

INTRODUCTION: Loss of bone mass occurs slowly and quietly, often with no symptoms until the first fracture. Osteoporosis is a systemic skeletal disease, characterized by low bone mass and structural deterioration of bone tissue, which increases the brittleness of the bones, which leads to an increased likelihood of fractures of the hip, spine and forearm.

OBJECTIVE: To present percentage of osteopenia and osteoporosis in people who are treated in the outpatient clinic Simin Han.

METHOD: Bone density screening by ultrasound measurement of the heel bone of respondents who live in the suburb area. The result of the T-score up to -1 is interpreted as normal value, the T-score between -1 and -2.5 as osteopenia and T-score above -2.5 as osteoporosis.

RESULTS: Total of 128 persons aged over twenty-five were in the scope of screening test. Out of the total number, there were 120 (93.5%) women and eight (6.5%) men. The average age of patients was 56. Total of 26 patients (20.31%) had normal finding (T - value up to -1). 66 (51.56%) patients had Osteopenia and T-score between -1 and -2.5. Osteoporosis and T-value equal to -2.5 or below was found in 36 (28.12%) persons, in 2 (1.56%) male and 34 (26.56%) female patients.

CONCLUSION: Obtained results show us that we have to start the prevention of osteoporosis as early as possible. In the treatment of osteoporosis, primary and most rational therapeutic principle is its prevention, ie. stopping the loss of bone mass and preventing the occurrence of any undesired complications or fractures. Proper nutrition is the most important in every stage of prevention and treatment of osteoporosis. This primarily refers to the consumption of calcium and vitamin D. It is also necessary to advocate the increase of level of physical activity at all ages.

The sexual dysfunction among the patients with colostomy and its relation with self-esteem

Onur Öztürk¹, Bektas Murat Yalçın², Mustafa Ünal², Kadir Yıldırım³, Nuraydın Özlem³

¹Atakum Community Health Center, Samsun, Turkey

²Department of Family Practice, Ondokuz Mayıs University Medical Faculty, Samsun, Turkey

³Department of General Surgery, Samsun Education and Research Hospital, Samsun, Turkey

OBJECTIVE: In this study, the sexual problems which might be faced in patients of different genders with temporary or permanent colostomy and the relationship between these problems and self-esteem.

MATERIALS-METHOD: 42 participants with temporary and permanent colostomy (study group) in Samsun Education and Research Hospital and 42 participants working as auxiliary staff in the same hospital (control group) were included in the study. All participants were applied a questionnaire containing the socio-demographical qualities, Rosenberg Self-Esteem Scale, female participants were given The Female Sexual Function Index and male participants were given The International Index of Erectile Function by sealed envelope method. After a week the data collected from the questionnaires were evaluated among groups.

FINDINGS: In the study group, 17 of 42 cases (40%) had permanent and 25 had temporary colostomy. Self-esteem of the cases in study group were lower ($1,01 \pm 1,13$) than the control group ($0,5 \pm 0,44$) ($p=0,021$). There was a meaningful relationship between the IIEF score of male patients and self-esteem scale ($r=0,123$, $p=0,013$). In the study group, male cases ($45,00 \pm 23,71$ points) had lower scores ($59,0 \pm 21,31$ points) than the control group in IIEF test ($p=0,026$). Females with colostomy had a significantly lower score than the control group only in "arousal" sub group ($p=0,045$). Males with colostomy has a higher score than the permanent group in IIEF score and all sub groups and females had higher scores in the arousal, satisfaction and pain sub scales.

CONCLUSION: Cases with permanent colostomy have more serious sexual problems than those with temporary colostomy. More detailed studies are needed on sexual problems faced by patients with colostomy.

Mood And Behavioral Changes Associated With Montelukast Usage In Pediatric Cases

Banu Gulcan Öksüz¹, Mahir İğde¹, Onur Öztürk²

¹Department of Pediatrics, Samsun Education and Research Hospital, Samsun, Turkey

²Atakum community health center, Samsun, TURKEY

AIM: As leukotriene antagonists are known to be safe in pediatric cases, their side effects should be considered. The purpose of this study is to evaluate the mood and behavioral changes arised with montelukast treatment in pediatric cases.

Patients and METHODS: A retrospective study was enrolled with the records of totally 172 patients, 97 of whom were considered as the study group and had the diagnoses of allergic diseases like asthma, allergic rhinitis, etc. and were given montelukast treatments, 75 of whom were considered as the control group and had the diagnoses of allergic and non allergic diseases and were not given montelukast treatments. All patients' demographical datas, mood and behavioral situations of the all allergic and non allergic patients at the beginning of the study, mood and behavioral changes in the allergic study group patients before montelukast treatments (group A), during montelukast treatments (group B) and after montelukast treatments (group C) were evaluated. RESULTS: Mean of age was 6.11 in the study, 8.12 in the control group (p=0.798). All of the asthmatic patients and all of the non asthmatic patients did not differ from each other in mood and behavioral disorders existed at the beginning of the study (p>0.05). Sleep disturbance (p=0.021), irritation (p=0.000), aggressiveness (p=0.004) and hallucination (p=0.031) were observed more in group B when compared with the patients in group A. Mood and behavioral changes seen in group C did not differ from group A (p>0.05).

CONCLUSIONS: Patients who are mentally stable before montelukast treatments may have some disturbances in mood and behaviors during treatments so attention should be paid for such reactions. Clinicians should suspect if the patient has unexpected reactions after montelukast. And further studies are needed to evaluate these datas.

Keywords: Asthma, Hallucination, Montelukast, Pediatric

A study of the referrals made from Primary Medical Care to Dermatology. Is there agreement in the diagnosis?

Maria Jose Agueros Fernandez¹, Mirna Lizzeth Centeno Cabrera¹, Carlos Fernandez Galanche¹, Alvaro Perez Martin², Jose Ramon Lopez Lanza³, Patricia Noemi Aguilera Samaniego¹, Montserrat Gago Bustamante⁴, Cecilia Traspuesto Pascual², Isabel Muñoz Franco², Maria Antonia Gandara Revuelta¹, Maria Angeles Pereda Garcia¹, Luis Rioja Zarrabeitia⁵

¹Primary Health Center Zapaton. Torrelavega. Spain

²Primary Health Center Centro. Santander. Spain

³Primary Health Center Alisal. Santander. Spain

⁴Primary Health Center Los Carmenes. Madrid.

⁵Primary Health Gerencia. Santander

Background & AIM: To study the level of diagnosis agreement and clinical actions taken with regards to referrals to Dermatology from Primary Medical Care.

METHOD: Analysis of all the patients referred to Dermatology from an urban primary medical centre, over the period January – June 2013, comparing clinical actions, completion of the referral note and diagnosis made at each level.

RESULTS: 354 subjects were referred, with an average age of 43.97 (SD 25.4), and predominantly female. The main motives were dermatitis, (12.1%), skin lesions (11.3%), melanocytic naevi (8.2%). The average time for referral was 51.03 days, 11.6% being referred at the time of the first consultation. 1.7% had some sort of diagnostic test (100% blood test), and 25.4% were prescribed a treatment before attending the specialist consultation (topical corticoides 33.3%). Once in Dermatology, 8.2% had some kind of test (82.8% biopsy), 33.6% were treated (removal 29.4 %). With regards to the completion of the referral note, at primary care level, it was correctly completed in 61.3% of the cases, and the response was noted in the medical records in 29.9% of cases (there was no report in 55.4% of cases). The Kappa index of diagnosis agreement between levels was 0.13, which is considered low.

CONCLUSIONS: There is a low level of diagnosis agreement between levels, which supposes there is little knowledge of the pathologies, although there is also a lack of documented response. The poor description of the pathology on the referral note is noticeable, as is the lack of later entering the response onto the medical records. There are few immediate referrals and use of diagnostic tests and treatments at primary medical care level. Strategies should be found to improve the registering of the information at both levels.

The objective of this study is to elucidate the use of ultrasonography guided fine-needle aspiration biopsies (UG-FNAB) in the evaluation of thyroid nodules. The study population consisted of 790 UG-FNAB in 719 patients whom were admitted to the our endocrinology clinic. The cytological results were classified as benign, follicular lesion or suspicious for malignancy,

malignant and non-diagnostic. The results of 790 UG-FNAB of 719 patients were as follows: 567 (71.77%) benign, 97 (12.28%) non-diagnostic cytology, 43 (5.44%) atypia with undetermined significance, 81 (10.25%) follicular lesion or suspicious for malignancy, 2 (0.25%) malignant. In our study, thyroid carcinoma rate was found to be lower than current literature. Of the malignant nodules which were reported as papillary thyroid carcinoma by UGFNAB cytology, both were female, euthyroid and have single nodule in their thyroid gland. One of the patient (39 years old) had a micro nodule (< 1 cm in diameter) that it had an isoechoic pattern with regular margin on thyroid ultrasonography; whereas the other one (79 years old) had macro nodule (>1 cm diameter) that it had, hypoechoic pattern with irregular margin. None of them have calcifications in their nodules. Multidisciplinary approach including endocrinologists, radiologists and pathologists is essential for the management of patients with thyroid nodules to avoid misestimation of the risk of thyroid cancer.

The Role of Drinking Alcohol, Coffee and Tea Habits in Smoking Cessation Success

Izzet Fidancı, Ismail Arslan, Oğuz Tekin, Enes Gümüş, Şükrü Ümit Eren, Mustafa Ülkü Uçkan
Department of Family Medicine, Ankara Training and Research Hospital, Ankara, Turkey

INTRODUCTION: The smoking cessation are one element of the biopsychosocial approach to family medicine. We aimed to evaluate the role of drinking alcohol, coffee and tea habits in smoking cessation success.

MATERIALS-METHODS: In our study, we applied a questionnaire and Fagerström Test for Nicotine Dependence to 128 participants consulting Family Medicine Smoking Cessation Outpatient Clinic of Ankara Training and Research Hospital. Among participants, 67 of them were people quitted smoking while the other 61 did not. With questionnaire, we investigated factors possibly affecting smoking cessation success like drinking alcohol, coffee and tea habits and also marital status and occupations of participants. By adding Fagerström Test for Nicotine Dependence to questionnaire we defined the dependence status of participants.

RESULTS: Study comprised of 128 participants, 50 of them being female and 78 being male. Mean age of participants was 34.01 (± 12.24) in patients quitted smoking and 32.82 (± 13.45) in patients still smoking. Tea and alcohol drinking habits were found to be higher in smoking group and difference was statistically significant ($p < 0,05$). When examining smoking cessation success according to occupational groups, civil servants and unemployed people were more successful than other occupational groups, but there was no statistically significant difference. People having coffee drinking habits quitted smoking in a significantly higher rate ($p < 0,05$). Among given treatments, although statistically insignificant, the most effective one was varenicline.

CONCLUSION: According to our results, smoking cessation success is lower among people having tea and alcohol drinking habits. In smokers, we should investigate the relationship with additional substance usage and aim to decrease these additional substance usage habits for increasing smoking cessation success.

Are guides to diabetes good for anything other than gathering dust?

Maria Jose Agueros Fernandez¹, Alvaro Perez Martin², Jose Ramon Lopez Lanza³, Montserrat Gago Bustamante¹, Patricia Noemi Aguilera Samaniego², Maria Angeles Pereda Garcia¹, Javier San Juan Minchero², Cecilia Traspuesto Pascual², Isabel Muñoz Franco², Maria Antonia Gandara Revuelta¹, Antonio Alonso Gonzalez², Maria Teresa Garcia Gutierrez²

¹Primary Health Center Zapaton. Torrelavega. Spain

²Primary Health Center Centro. Santander. Spain

³Primary Health Center Alisal. Santander. Spain

Background & AIMS: The analysis of the characteristics of diabetic patients, the degree to which recommendations appearing in guides are followed, and the attitude of the doctors towards these.

METHOD: A descriptive transversal study of diabetic patients attended to in one urban primary health center. To calculate the correct control, the values recommended by the ADA 2015 were used (blood pressure (BP) <140mmHg and <90 mmHg, LDL <100mg/dl). To assess renal failure, a <60 filtration rate was used. The average was used for quantitative values and percentages were used for qualitative variables..

RESULTS: 60 subjects were selected (96.7% type 2 diabetes), with an average age of 70.48 (SD ± 12.8) and mainly male (50.8%). The average values encountered were HbA1c 7.4(DE1.72) %, glycemia 146.8 (SD 62.1), LDL 100.54 (SD 30.9) mm/dl, systolic blood pressure (SBP) 142.52 (SD 17.08) mmHg and diastolic blood pressure (DBP) 75.83 (DE 9.9) mmHg. 16.4% fulfilled the BP control figures, 59% the LDL control figures, 20.3% presented renal failure. With regards to treatment, 41.3% used monotherapy for high blood pressure, mainly diuretics (51.7%). Of those who did not fulfill the medical objectives, the doctor did not carry out further treatment in 85.7% of those with high BP (change of pharmaceutical medicine in 82.9% of cases, increased dosage in 14.5%) and in 93.1% in the cases of high LDL (adding a hypolipidemic drug in 78.4% of cases).

CONCLUSIONS: The degree of control of risk factors (hypertension and cholesterol) in diabetic patients is very deficient, as it does not fulfill the recommendations given by the main guides. There is a great deal of therapeutic inertia among the doctors, which means that treatment to lower cardiovascular risk should be reviewed and intensified.

Delivery Preferences of Women and Influencing Factors

Gülsüm Özçelik¹, Merve Gülbahar¹, Emine Karahan¹, Ziya Mirzaev¹, Nahida Velihanova¹, Abdulkadir Kaya²

¹Ataturk University Medical Faculty

²Ataturk University Medical Faculty Department of Family Medicine

AIM: In this study, we aimed to investigate preferences of women in routes of delivery and influencing factors.

METHOD: This study was performed at Atatürk University Hospital during September 2013. Fifty concomitant pregnant women applying for delivery were included in the study. A questionnaire with 16 questions querying the delivery preferences of women was applied to all participants. Results were analyzed using the SPSS software.

RESULTS: Almost all participants were married (n=48, %96). Mean age was 36.7 ± 7.1 years. Mean number of children was 2.7 ± 1.2. Mean age at first delivery was 22.2 ± 3.6. Fifty eight percent (n=29) of the participants delivered their first baby with cesarean section. 23 of the deliveries (46%) were by normal vaginal route while 27 (54%) were via cesarean section. Mothers preferring cesarean section mentioned their own health and baby's health as the first most common reasons (each n=9; 33.3%). Other reasons mentioned were indication given by the doctor (n=7; 25.9%), being afraid of normal delivery (n=1; 3.7%), and the comfort of cesarean section (n=1; 3.7%).

DISCUSSION: This showed that the most important reason of women preferring cesarean section is their concerns regarding the own and baby's health. We concluded that the high proportion of cesarean deliveries may be due to the sample coming from a tertiary hospital. The fact that women have a misconception that cesarean delivery

will be good for their own health and baby's health raises the importance of educating and informing pregnant women for the benefits/risks of delivery types.

Medical Specialization Exams Between 2007 and 2013: A Trend Analysis

Abdulkadir Kaya, Zekeriya Aktürk, Yasemin Çayır, Kenan Taştan
Ataturk University Medical Faculty Department of Family Medicine
Background and design

Since 1987 Turkish medical doctors have to enter the specialization exam, TUS which is done twice a year in order to be placed to a residency training program. There is a recent change in the preferences of residency candidates with probable effects of factors such as the Health Transformation Project, full-time employment act (#5947), and increased numbers of malpractice lawsuits.

The aim of this study was to investigate TUS quota and scores between the years 2007 and 2013 and analyze changes in the trends with regard to specialty preferences.

Materials and methods

Data for the 13 TUS exams between April 2007 and April 2013 were analyzed by downloading relevant booklets from the web page of the examining organization Center for Measurement, Selection, and Placement (<http://www.osym.gov.tr/>). The main outcome measure was mean minimum scores of the TUS exam. Statistical analysis was done with the SPSS 18.0 software.

Results

While there was an increase in the mean scores for Medical Biochemistry and Medical Microbiology, there was a drop in the scores for Gynecology and Obstetrics, General Surgery, and Pediatrics residencies. Mean scores for residency programs of the Ministry of Health were 62.3 ± 2.6 compared with 61.8 ± 2.0 for residency programs run by universities, without any statistically significant difference ($t=1,18$; $p=0,241$).

Surgical disciplines being more prominent, there was a drop in the scores in disciplines with inpatient services compared to those without inpatient service. This difference was statistically significant in the year 2007 ($F=4.691$; $p=0.02$) but became non-significant thereafter ($p>0,05$).

Conclusion

The trend in residency preferences of medical doctors in Turkey is changing. This trend should be taken into consideration when planning quota for residency positions in order to prevent imbalances in the specialist doctor workforces.

Effect of peganum harmala L. on Lipid metabolism and changes Cyp7a1 Enzyme in Male Wistar Rat

Ali Mohammad Eini¹, Majid Moharrami Fard², Mehdi Ahmadi Far³

¹Ali Mohammad Eini

²Majid Moharrami fard

³Mehdi Ahmadi far

AIMS:

Concentration of cholesterol and other lipids in human diet has been considered as an issue of public health. In the present study the Effects of peganum harmala (P. harmala) on lipid metabolism were investigated in a 28-days feeding trial.

METHODS:

Total of 64 rats (200 ± 15) were divided into six groups: (G1) control, (G2) control plus 100mg/kg, (G3) control plus 200mg/kg, (G4) control plus 400mg/kg., experimental was 8 weeks period. the blood and liver tissue samples for serum lipid profile were collected and Cyp7a1 Enzyme determined.

RESULTS:

Plasma glucose was changed by dietary treatments. Peganum harmala (P. Harmala) decreased low density lipoprotein LDL in (200,400) mg/kg of the Extract groups and increased high density lipoprotein cholesterol in (100) mg/kg of the Extract groups significant difference ($P < 0.05$), but decreased plasma triglycerides only in 100 mg/kg of the diet group.

The results show that with increasing extract dose, CYP7A1 gene expression is increased significant difference ($P < 0.05$)

Conclusions

It is concluded that methanolic extract of P. harmala could be effectively used in rat to optimize serum lipid profile. These results demonstrate that P. harmala increases the effect of excretion cholesterol and Cyp7a1 enzyme.

The Associations of 'Fatness', 'Fitness' and Physical Activity With All-Cause Mortality in the Elderly: A Systematic Review Of Observational Studies

Dharani Yerrakalva, Ricky Mullis, Jonathan Mant

Cambridge University

BACKGROUND: In older adults, unlike the general adult population, increasing adiposity is associated with better health outcomes. This is the so-called 'obesity paradox'.

AIM: This review sought to explore whether the obesity paradox in older adults might be explained by confounding or effect modification by cardiorespiratory fitness or physical activity.

METHODS: Systematic searches were carried out to identify observational studies that examined the association of adiposity markers (body mass index, waist circumference and waist-hip ratio) with all-cause mortality in older adults (aged ≥ 60) and took into account cardiorespiratory fitness or physical activity. Studies were eligible if they included at least one adiposity measure, and reported all-cause mortality that was either adjusted or stratified for either cardiorespiratory fitness or physical activity measures. Data from each included study was analysed to produce a graphical representation of the relationship of adiposity markers with all-cause mortality.

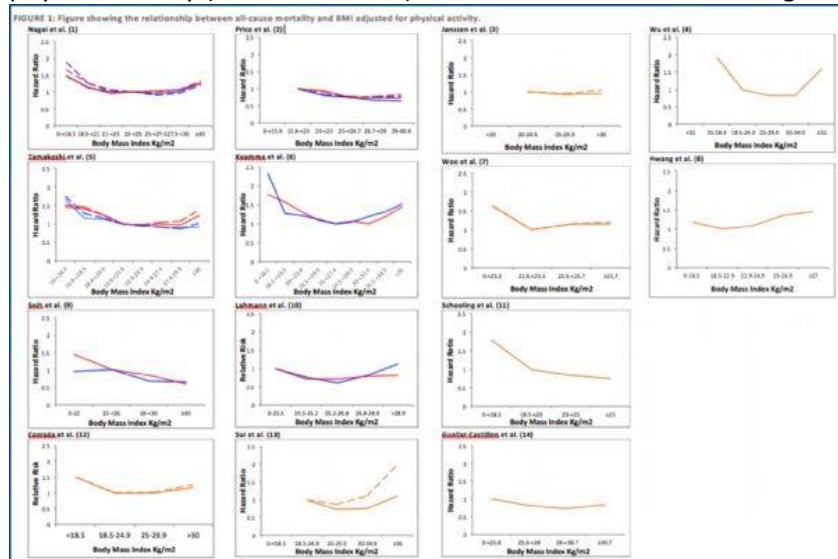

RESULTS: 15 observational studies were identified. 14 of these studies found that increasing BMI had a non-positive association with all-cause mortality, with persistence of the obesity paradox despite adjustment for physical activity or cardiorespiratory fitness. Two studies found that low fitness was associated with mortality risk regardless of BMI while fit and overweight individuals had similar mortality risk as their normal weight counterparts. Few studies utilised central adiposity measures and no consistent pattern emerged with regard to their association with all-cause mortality.

CONCLUSIONS: The limited available evidence suggests that physical activity or cardiorespiratory fitness are not confounding the relationship between adiposity markers and mortality, but cardiorespiratory fitness may be acting as an effect modifier. The risk of death associated with being overweight or obese may differ depending on fitness but this is based on only two studies which used stratification as opposed to post-hoc adjustment. More

work is needed in this area.

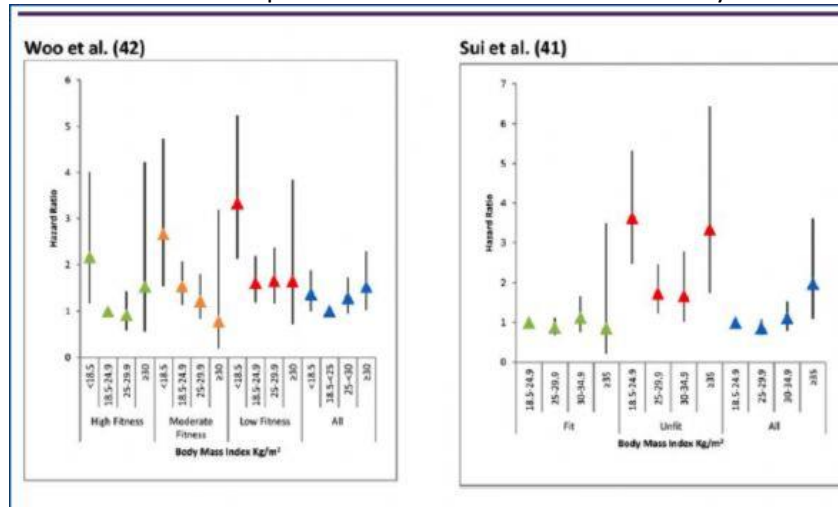

Keywords: Obesity, Fitness, Physical Activity, Mortality, Elderly

FIGURE 1: Relationship between BMI and all-cause mortality after adjustment for cardiorespiratory fitness or physical activity (all other studies) for included studies with enough extractable data.

Relationship lines in orange denote both sexes, in red denote females, and in blue denote males. Dashed relationship lines denote pre-adjustment, and solid lines denote post-adjustment. Some studies did not provide combined sex data or pre-adjustment data.

FIGURE 2: Relationship between BMI and all-cause mortality with stratification for fitness.

. This figure is a graphical representation of the findings of the only two studies that stratified for cardiorespiratory fitness. The first graph shows data from Sui et al. (13) cohort from the Aerobics center Longitudinal Study. Hazard ratios for fit groups are in green and unfit groups in red with vertical lines representing 95% confidence intervals. The second graph is data from Woo et al. (7), a Hong Kong community cohort using 6 metre walking speed as a cardiorespiratory fitness surrogate measure. Hazard ratios for high fitness groups are in green, moderate fitness in yellow, and low fitness in red with vertical lines representing 95% confidence interval.

Quality of life in patients with type 2 diabetes mellitus and patients with osteoarthritisMarinela Đaković¹, Kosana Stanetić²¹Primary Health Center Laktaši, BiH²Primary Health Center Banja Luka, BiH

Background and AIM: Diabetes mellitus type 2 and osteoarthritis are diseases which significantly impact patients' quality of life. The aim of the study was to evaluate and compare the quality of life in patients with type 2 DM and patients with osteoarthritis.

METHODS: Interview-based study was conducted among patients with type 2 DM and patients with osteoarthritis. SF-36 questionnaire for assessing quality of life and a questionnaire with socio-demographic data were used as surveying instruments. The entry criteria included the following: patients aged 45 to 75 years, Group 1 - patients with type 2 DM and Group 2 - patients with osteoarthritis, both without comorbidities that may significantly affect the quality of life.

RESULTS: A total of 60 patients were included in the study, of whom 30 (50%) with type 2 DM and 30 (50%) with osteoarthritis, 27 (45%) male and 33 (55%) female patients. Statistically significant differences between two groups of examinees were found in the following areas of functioning: physical functioning ($p = 0.000$), activity limitations due to physical problems ($p = 0.001$), activity limitations due to emotional problems ($p = 0.015$), energy / fatigue ($p = 0.005$) and pain ($p = 0.000$). Group of patients with osteoarthritis had worse results regarding all mentioned areas of functioning. Summary results of physical functioning ($p = 0.000$) and summary results of mental functioning ($p = 0.017$) showed that the group of patients with osteoarthritis had significantly worse functional outcome than the group of patients with type 2 DM.

CONCLUSION: Although DM type 2 is more serious disease than osteoarthritis, the quality of life of the patients with osteoarthritis was significantly worse than in patients with type 2 DM.

Advance care planning in primary care, only for severely ill patients? A structured review

Jolien J. Glaudemans, Eric P. Moll Van Charante, Dick L. Willems

Department of General Practice, Section of Medical Ethics, Academic Medical Center – University of Amsterdam, Amsterdam, the Netherlands.

Background and AIM: Increasing medical possibilities, ageing of the population and the growing number of people with chronic illness appear to make advance care planning (ACP) inevitable. However, to what extent and how primary care providers (PCPs) provide ACP in daily practice is largely unknown. The aim of this review is to provide a literature overview of the actual practice of ACP in primary care.

METHOD: We searched MEDLINE, EMBASE, CINAHL, PsycINFO and the Cochrane Library for empirical studies that described the practice of ACP with patients in primary health care. Studies focussing on non-adult patients, and hospital or nursing home settings were excluded.

RESULTS: Ten articles met the inclusion criteria. The content of the ACP varied from discussing to refrain from cardiopulmonary resuscitation to existential issues. The prevalence ranged from 21% of PCPs having ACP discussions with the general elderly population to 69% having ACP discussions with terminal patients and 81% with patients with mild to moderate Alzheimer's disease. ACP was more common among cancer patients than among patients with non-cancer patients. Whether health care professionals or patients initiated ACP varied greatly. Advance directives and the Gold Standard Framework were perceived as helpful to guide ACP.

CONCLUSIONS: ACP does not seem to have a systematic place in the care for all community-dwelling older people. Rather, it is used for specific groups, like patients with terminal disease, cancer and Alzheimer's Disease. Whether ACP might have beneficial effects for a broader primary care population, in terms of future care planning, is yet to be investigated.

Quotes

After an elderly woman switched to the practice of GP18 the GP and the woman talked about her wish to donate her body to science; 'Thereafter we talked about how she was living on her own, that she had less and less family left and about her blindness. She often needed help but said 'life is still is nice, but I don't want everything anymore.'

GP 11 talked with the family of an elderly woman with heart failure and dementia; 'if your mother would get a pneumonia and I think she could die from it, what would you think in such situation? Would you want her to be treated in the hospital, or should I treat her here with antibiotics and see if she'll make it or not?'

GP 3 counselled an elderly man with a history of CVA on anti-hypertensive treatment; 'He said that if refraining from medication would lead to a new, non-fatal stroke with decreased quality of life, he would rather use the medication. Yet he would not mind dying of another stroke. Quality was all that mattered to him.'

P-0986

Prevalence of mental disorders in family medicine practice

Olivera Batic Mujanovic¹, Jasminka Becirovic², Larisa Gavran³, Esad Alibašić⁴, Munevera Becarevic⁵

¹Family Medicine Teaching Center of Health Center Tuzla; Department of Family Medicine, Medical Faculty of Tuzla University, Tuzla, Bosnia and Herzegovina

²Health Center Srebrenik, Srebrenik, Bosnia and Herzegovina

³Family Medicine Teaching Center of Health Center Zenica, Zenica, Bosnia and Herzegovina

⁴Health Center Kalesija, Kalesija, Bosnia and Herzegovina

⁵Health Center Banovici, Banovici, Bosnia and Herzegovina

BACKGROUND & AIM: Over one-quarter of all adults attending primary care centers in Bosnia and Herzegovina has at least one type of mental disorder. The aim of this study was to determine the prevalence of mental disorders in family medicine practice related to age, gender, and diagnosis of mental disorders in adults over the age of 18 who attended primary care center in Tuzla, B&H.

METHODS: Trial was conducted in Family Medicine Teaching Center Tuzla and included 155 patients (108 women and 47 men) registered in family medicine team. Data were collected according to the age, gender, and diagnosis of mental disorders.

RESULTS: Prevalence of mental disorders was 9,69% (155/1445). Statistically more women had diagnosis of mental disorders than men (69,68% vs. 30,32%; $p < 0,0001$). Mean age of patients were $55,22 \pm 13,55$ years, without significant difference between women and men ($55,22 \pm 12,92$ vs. $51,58 \pm 15,87$; $p = 0,29$). Majority of patients belonged to the age group 20-64 years (75,48%), while 24,25% of patients were older than 65 years. The leading mental disorders were neurotic, stress-related and somatoform disorders (F40-F48) presented in 46,45% of patients. Mood disorders (F30-F39) had 43,23% of patients. Schizophrenia, schizotypal and delusional disorders (F20-F29) had 7,1%, and other mental disorders (F04-F09, F50-F69, F80-F99) had 1,29% of patients. Alcohol abused 1,29% of patients (F10). Overall 60 (38,71%) patients were treated by family physician, while 95 (61,21%) attended mental health center. Psychotherapy was performed in 25% of patients. Majority of patients used pharmacological therapy over two years (74,19%). The most prescribing drugs were SSRI antidepressants (63,23%), while benzodiazepines used 49,68% of patients.

CONCLUSION: Mental disorders are still quite prevalent among the adults attending primary care centers in Bosnia and Herzegovina. It suggests the need for an integrated approach to general medical and mental health treatment in order to provide mental health care with confidence.

Could it be colorectal cancer? General Practitioners' use of Faecal Occult Blood Tests and decision-making - a qualitative study

Cecilia Högberg¹, Mikael Lilja¹, Eva Samuelsson¹, Eva Fhärm²

¹Department of Public Health and Clinical Medicine, Unit of Clinical Research Centre - Östersund, Umeå University, Umeå, Sweden

²Department of Public Health and Clinical Medicine, Family Medicine, Umeå University, Umeå, Sweden

Background & Aim

Abdominal complaints are common reasons to contact General Practitioners (GPs), and selecting the patients with suspected colorectal cancer (crc) to refer for further investigation can be a challenge. Faecal Occult Blood Test (FOBT) is commonly used as a diagnostic aid. It is however uncertain how FOBT results are interpreted. Studies have shown that negative tests are associated with a risk of delayed diagnosis, and that some patients with positive tests are not investigated further. The aim was to explore what makes GPs suspect crc, their practice concerning investigation and decision-making, and the use of FOBT.

Method

Semi-structured individual interviews were made with eleven GPs in Region Jämtland Härjedalen, Sweden, and analysed with qualitative content analysis.

Results

Five categories were identified:

Careful listening to the patient's history required: To listen attentively was described as essential, but with a risk of being misled by the patient's own explanations.

Laboratory tests can be of help - FOBTs can help or complicate: Anaemia was considered an important factor. All used FOBTs to different extents, but interpretation of the results and actions taken varied.

To refer or not to refer - safety margins necessary: Uncertainty was described as a part of everyday work.

Common vague symptoms could be crc and justified referral with safety margins.

Growing more confident - yet humble: With increasing experience the GPs described becoming more confident in decisions but also more humble and less prestigious.

The patient's advocate: The GPs strived to keep the patient's best in focus in a changing reality.

Conclusions

In deciding which patients to refer careful listening to the patient's history was found essential. FOBTs were frequently used as support, with a considerable variation in handling of the test results. The diagnostic process can be described as navigating uncertain waters with safety margins.

Keywords: Colorectal Neoplasms, Occult blood, Decision Making, Qualitative Research

Quotes from the interviews

1. Careful listening – with awareness of the pitfalls

"It's the patient that knows how things were. ... If something brings the patient to me because he or she feels that something is different, then there is in fact a change." (GP2)

"Sometimes, patients have their own explanations, which may act as a kind of smoke screen. ... The explanation they come up with can ultimately delay things." (GP3)

2. Tests can help – the iFOBT can also complicate the diagnosis

"Yes, they're of huge help, yes. ... They're of crucial importance." (GP6)

"Yes, they serve as an indication." (GP8)

"In reality, they're not so useful. ... They don't help me very much, I'm hesitant to the usefulness of faecal occult blood tests." (GP5)

3. To refer or not to refer – safety margins are necessary

"The level of investigation must have a safety margin ... Otherwise, we're too restricted in our investigations." (GP6)

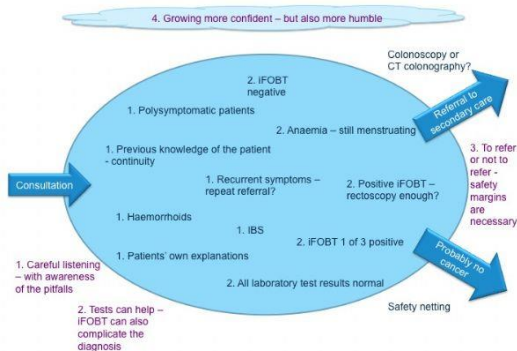

"Most of what we investigate turns out to be nothing. ... You have to draw the line somewhere and keep a cool head and wait a while." (GP7)

4. Growing more confident – but also more humble

"I almost feel like I can be more generous with my referrals for bowel imaging now than I was previously, because with time you see how difficult it is. Suddenly, someone you didn't think had a malignancy actually has one." (GP6)

"I've worked for quite a few years ... there's no work prestige involved. ... I don't really care if there is someone at the other end that laughs at my referral ... it's not my problem." (GP9)

The GP's way to decision on referral

The patient and the doctor together enter the sea of consultation. The doctor has to navigate past the shoals belonging to category 1 and category 2. The doctor and the patient together arrive at the decision to refer to secondary care or not, category 3. All the way the cloud of experience is a companion, category 4.

Development of a simple tool for identifying alcohol use disorder in Korean female drinkers from previous questionnaires

Yuri Seo

Department of Family Medicine, Research Institute for Medical Sciences, Chungnam National University School of Medicine, Korea

BACKGROUND: This study aimed to develop a simple tool for identifying alcohol use disorders in Korean female drinkers from previous questionnaires.

METHODS: This research was conducted with 400 women who had a drink during the past month, visiting the Chungnam National University Hospital from June 2013 to May 2014. Drinking habits and alcohol use disorders were assessed by structured interviews using the DSM-5 diagnostic criteria. At the same time, the subjects were asked to answer the AUDIT, AUDIT-C, CAGE, TWEAK, TACE and NET questionnaires. The AUROC of each question of the questionnaires on alcohol use disorders was assessed. After combining two questions with the largest AUROC, it was compared to other previous questionnaires.

RESULTS: Among the 400 persons, 58 (14.5%) were identified as those with alcohol use disorders. Two questions with the largest AUROC were Question No. 7 in AUDIT, "How often during the last year have you had a feeling of guilt or remorse after drinking?" and Question No. 5 in AUDIT, "How often during the past year have you failed to do what was normally expected from you because of drinking?" with an AUROC (95% CI) of 0.886 (0.850 - 0.915) and 0.862 (0.824 - 0.894). The AUROC (95% CI) of the combination of the two questions was 0.958 (0.934 - 0.976) with no significant difference as compared to the existing AUDIT with the largest AUROC.

CONCLUSION: The above results suggest that the simple tool consisting of Questions No. 5 and No. 7 in AUDIT is useful in identifying alcohol use disorders in Korean female drinkers.

⁷Mumtaz M. Mazicioglu, (M.D.), Prof, Department of Family Medicine, Erciyes University School of Medicine, Kayseri, Turkey

PURPOSE: The aim of this study is to determine the prevalence and related factors of restless leg syndrome (RLS) in the community-dwelling elderly living in Kayseri.

METHODS: This is a cross-sectional population based study in 960 community-dwelling elderly living in an urban area. We sampled 1/100 of elderly people aged 60 years and older. The diagnosis of RLS was made according to the criteria of the International RLS Study Group (IRLSSG). The demographic data were collected by face-to-face interviews. Additionally, the Mini-Mental State Examination (MMSE), Geriatric Depression Scale (GDS) and anthropometric measurements were used. Logistic regression analyses were performed to define risk factors for RLS.

RESULTS: We excluded elderly people with cognitive impairment (295). One hundred and five (15.8%) of the remaining 665 elderly subjects met the criteria to diagnose RLS. There was female predominance (3/1). Gender, length of education, employment status, smoking, hypertension (HT), diabetes mellitus (DM), depressive mood, high body mass index (BMI), and high waist circumferences (WC), sleep quality, sleep duration, and difficulty in falling asleep in the first 30 minutes were all detected as risk factors for RLS. However in logistic regression analysis, being a housewife, sleeping less than 6 hours a day, and having diabetes were found as significantly related risk factors for RLS.

CONCLUSION: This is the first epidemiologic study of RLS conducted in the Turkish community-dwelling elderly in an urban area. RLS is a common but underestimated disease in the elderly. Although RLS is prevalent we found very few risk factors for RLS.

Keywords: Restless leg syndrome; elderly; community-dwelling; sleep disorder; sleep quality.

Table 1: The diagnostic criteria of the International RLS Study Group

1. Desire to move the limbs usually associated with uncomfortable and unpleasant sensations, motor restlessness
2. Worsening of symptoms during periods of rest or inactivity such as lying or sitting
3. The urge to move or unpleasant sensations are relieved by movement with at least partial and temporary relief by activity
4. Worsening of symptoms in the evening or night or only occur in the evening or night

Working Conditions and Health Status in Taxi and Bus Drivers at Çanakkale, Turkey; Community Based Study

Aysegul Uludag¹, Sibel Cevizci², Murat Tekin¹, Yusuf Haydar Ertekin¹, Sezgin Sevim², Ulken Babaoğlu³, Coşkun Bakar²

¹Department of Family Medicine, Canakkale Onsekiz Mart University, Canakkale, Turkey

²Department of Public Health, Canakkale Onsekiz Mart University, Canakkale, Turkey

³Health College, Ahi Evran University, Kırşehir, Turkey

BACKGROUND: The growing taxi and bus driver workforce is at risk for poor health status, obesity, hypertension, metabolic syndrome and with increased risk for cardiovascular disease.

AIM: to determine the relationship between working conditions and health status in taxi and bus drivers.

METHOD: This study is a descriptive study. The population of the study was taxi and bus drivers in central of Canakkale. There were 164 taxi drivers and 150 bus drivers who registered in The Chamber of Canakkale Drivers and Vehicle. We reached the 70 (42.7%) taxi drivers and 93 (62.0%) bus drivers in the study.

The participants were visited at their workplace. We performed the questionnaire that include the socio-demographic features, habits, disease history, the working conditions. We evaluated the blood pressure in both arms, waist-hip measurements and capillary blood glucose at any time.

RESULTS: There were 70 (42.9%) taxi drivers and 93 (57.1%) bus drivers. All of them were men. The socio-demographic and descriptive features are shown at Table 1.

Nine (12.9%) taxi drivers and 6 (6.5%) bus drivers were hipertensive, and 1 taxi driver and 2 bus driver with random capillary blood glucose levels higher than 200 mg. In this study, based on the ATP III criteria, the prevalence of Metabolic Syndrom was found 9.6%. Of the 8 (11.4%) taxi drivers and 8 (8.6%) bus drivers were met the criteria of ATP III.

There was statistical significant between HT and income level ($u=709.5$; $p=0.008$). Metabolic Syndrome and working hours was statistical significant ($u=750$; $p=0.015$). There was statistical significant between obesity and age and history of chronic disease ($u=2720$; $p=0.028$ and $u=2637$; $p=0.031$).

CONCLUSION: Drivers' working condition is related with Metabolic Syndrome, obesity and hypertension. All of them are the risk factors of cardiyovascular disease (CVD). These results may direct us to take precautions about their health status.

Does work-family conflict cause anxiety and depression in medical residents?

Özge Berfu Gürbüz, Vildan Mevsim

Department of Family medicine, Dokuz Eylül University, İzmir, Turkey

Background & Aim

Work family conflict leads to a higher rate of depression and anxiety in medical residents, and there wasn't enough data about the effect of it on anxiety and depression in Turkey.

The aim of the research is to evaluate the effect of work-family conflict on anxiety and depression in medical residents.

Method

This research was conducted as a thesis project and is at preliminary result stage. This was a cross sectional study carried among medical residents working at Dokuz Eylül University, during september to december 2014. By using simple randomized sampling, 215 residents were chosen to participate and fill a self administered questionnaire entailing data about sociodemographic characteristics, hospital anxiety depression scale, work-family conflict scale. As statistical analysis descriptive analysis, Chi-square test, student T test were applied.

Results

The study included 209 residents, %49,8 were female and % 50,2 male. Average age of participants was $28,28 \pm 3,09$. Average working condition score was $22,15 \pm 4,88$. %23,4 of the participants had anxiety and %30,6 had depression. %51,2 had work-family conflict and % 9,1 had family-work conflict. %57 of the participants who had work-family conflict, had depression and %43,9 of the patients with work-family conflict had anxiety. %10,5 of the participants with family-work conflict had depression and %5,3 had anxiety. The rate of anxiety and depression was higher in participants who had work-family conflict, compared to the ones who had work-family balance. Participants with family-work conflict also had a slightly increased anxiety and depression rate.

Work family conflict has a greater influence on anxiety and depression compared to family-work conflict.

Conclusion

Working conditions causes more conflict in residents' family life, where as family life causes less conflict on working life. Work-family conflict increases the rate of anxiety and depression in medical residents.

Metabolic syndrome and type 2 diabetes

Enisa Ramic¹, Esad Alibasic², Olivera Batic Mujanovic¹, Renata Smajlovic¹

¹Primary Health Care Center Tuzla

²Primary Health Care Center Kalesija

INTRODUCTION: Metabolic syndrome is a set of high-risk factors that lead to the development of coronary heart disease and type 2 diabetes. These factors are as follows: hypertension, glucose intolerance and elevated levels of plasma triglycerides while concentration of HDL-cholesterol is reduced. The two most important risk factors for the development of the metabolic syndrome are a large amount of weight around the abdomen (visceral obesity) and resistance of peripheral tissues cells to the effects of insulin.

OBJECTIVE: To determine the prevalence of metabolic syndrome in people with type 2 diabetes.

METHODS: The study included 120 patients with diagnosis of diabetes mellitus, who reported for medical examination in the time frame from September to December of 2014. Criteria for diagnosis of metabolic syndrome were any three of the five parameters: increased waist circumference (≥ 102 cm -in male; > 88 cm -in female), blood pressure $> 130/85$ mmHg, dyslipidemia (triglycerides ≥ 1.7 mmol/L, HDL-c < 1.0 mmol/L -male; < 1.3 mmol/L -female), fasting plasma glucose ≥ 6.1 mmol/L.

RESULTS: The study included 45 men (37.5%) and 75 women (62.5%). The average age was 67.18 ± 10.3 years. 51.66% patients had three or more parameters of the metabolic syndrome. In the subgroup of diabetic patients with metabolic syndrome, the increased waist circumference was present in 90.32% patients, blood pressure $> 130/85$ mmHg was present in 79%, and 74.19% patients had increased triglyceride levels.

Out of the total number of patients, 43.33% had preferred physical activity (≥ 30 min per day) and 56.66% patients had insufficient physical activity

CONCLUSION: The prevalence of metabolic parameters that make up the metabolic syndrome could be reduced by changing life style. Focused and continuous patient care allows us to make an influence on patients in a way of changing their habits, which is a basic and very effective measure for treating metabolic syndrome.

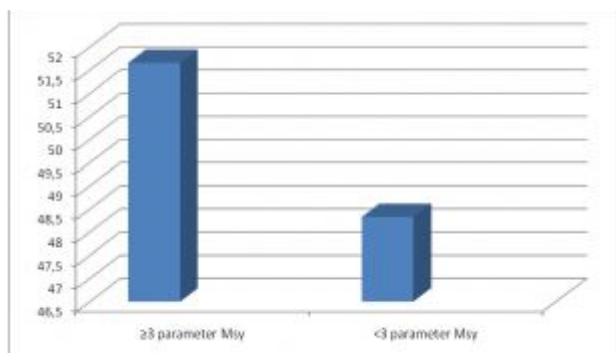

Keywords: metabolic syndrome, type 2 diabetes, parameters, life style

Screening of chronic diabetes complications among primary health care patients in Bosnia and Herzegovina

Natasa Damjanac¹, Valentina Kilibarda¹, Maja Racic²

¹Primary Care Health Centre Trebinje

²University of East Sarajevo

INTRODUCTION: Diabetes mellitus is a common chronic illness, which is associated with many chronic complications.

Objectives. In the present study, the audit of medical files of patients with diabetes followed in Family Medicine Teaching Centre Foca, Bosnia and Herzegovina (BiH), was carried out in order to investigate the frequency of the use of screening tests for early diagnosis of diabetes complications.

Methods. The audit was conducted among 192 patients with diabetes. Screening tests assessed are selected according to the ADA guidelines and included: blood pressure, body mass index (BMI), urine protein analysis, serum creatinine, dilated eye examination, foot examination, neurological examination and ankle-brachial index (ABI). The study was carried out in course of one-year period (March 2011 to March 2012).

Results. Frequency of the individual screening test varied between 92%, found for at least one blood pressure measurement, and 0.5% for ABI measurement. When the frequency of optimal use of screening was analyzed, only 0.3 % of patients received all recommended screening tests. The factors associated to low screening rate were male gender, diagnosis of type 1 diabetes and having more than 100 diabetes patients, registered with the practice. The physicians with completed vocational training in family medicine, belonging to the age group of 36 to 40 years and with the years of experience in the range between 11 and 15 were more likely to provide larger number of screening test for their patients compared to the other group.

Conclusion. The frequency of the use of screening tests for chronic diabetes complications was found to be low in Primary Health Care Centre Foca. There is a need for an improved screening awareness among primary care providers and a focus on enhancing screening practices among males and persons with other cardiovascular factors present.

"Burnout and Related Factors in Healthcare Workers"

Dilek Kusaslan Avci, Huseyin Avni Sahin

Department of Family Medicine, Medical Faculty of Yuzuncu Yil University, Van, TURKEY

AIM:

The aim of the study is to determine the prevalence of Burnout and related factors among Healthcare Workers in a university hospital.

METHODS:

A total of 179 health workers were included in the study working in a university hospital in Van. Research data were collected with a questionnaire consisting of two parts. In the first section questions regarding socio demographic information, smoking, drinking alcohol, hobbies and methods of coping with stress were included. The second section includes the results of Maslach Burnout Scale (MBI). MBI scale is composed of three dimensions; emotional exhaustion, depersonalization and personal accomplishment.

RESULT:

The study population consisted of 81 female (44.5 %) and 99 male (55.5 %). Participants were physicians (31.1%), nurses (47.8 %) and other employees (21.1 %). According to study 12.3 % of the females' and 22.4 % of the males' emotional exhaustion scores and 7.4 % of the females' and 12.2 % of the males' depersonalization scores were high. According to study, 26.1 % of the physicians', 8.5 % of the nurses' and none of other employees' depersonalization scores were high (p: 0.006). Furthermore, 55.9 % of the physicians, 21.3 % of the nurses and 6.2 % of other employees' emotional exhaustion scores were high (p: 0.271). All of the physicians', all of the other

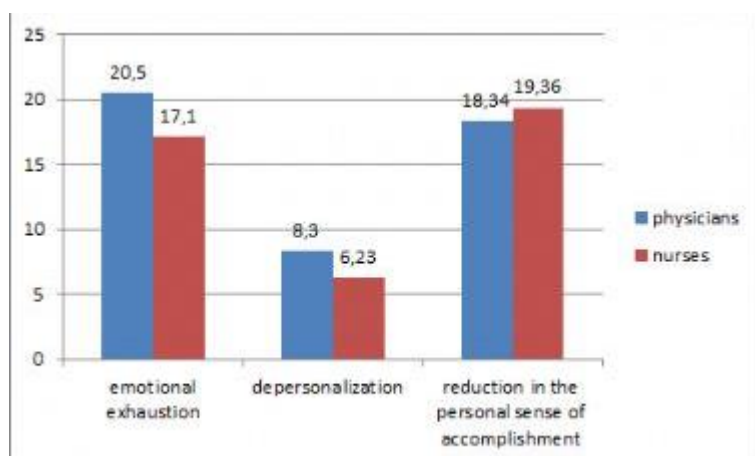

employees' and 97.9 % of the nurses had reduced sense of personal accomplishment (p: 0.000). Smokers had high-level of emotional exhaustion (30.8%) compared to non-smokers (11.6 %) (p: 0.024).

CONCLUSION:

The study showed that burnout rate among health care workers was very high. There was a significant relationship between the rate of burnout and smoking. Further attention and studies are necessary to reduce the burnout of health care workers.

Keywords: Burnout, personal achievement, emotional exhaustion, depersonalization, physician, healthcare workers

Complementary and Alternative Medicine in Patients with Diabetes Mellitus who Referred to University Hospital

Dilek Kusaslan Avcı, Huseyin Avni Sahin, Ercan Oner

Department of Family Physicians, Yüzüncü Yıl University, Van, Turkey

AIM: Complementary and alternative therapies are used widely in the treatment of Diabetes Mellitus (DM) in combination with or instead of standard medical care. This study was carried out as a descriptive study in order to examine the use of complementary and alternative medicine (CAM) in Diabetes Mellitus patients.

METHODS: Patients admitted to outpatient endocrinology clinics were given questionnaires involving age, gender, education, occupation, chronic illness, medication, use of herbal and nutritional complementary products, information resources and benefit of using herbs and nutritional complementary products. Data were evaluated by using SPSS computer software version 16.

RESULTS:

117 DM patients included in the study (63.2% women, 36.8% men). The overall use of CAM was 41.2 % among DM patients. Of the CAM used patients, 56.2% was women and 43.8 % was men. The most commonly used method was plants and herbal teas with a rate of 77.08 %. Patients stated that use of CAM are suggested by relatives (71.8), other diabetes mellitus patients (15.5 %), doctors (3.5 %), TV programs (2.6 %), herbalists (2.6 %), internet resources (1.8 %) and books (1.7 %). 29.9% of the patients share their CAM experience with their doctors and 4.3% of the patients' doctors asked to stop CAM. 12.8% of the patients stated that CAM therapies are beneficial, on the contrary 11.3% mentioned that CAM therapies are harmful to them. Even though all the patients excepting the use of CAM therapies by their doctors, only 1.3 % of the patients aware of doctors may

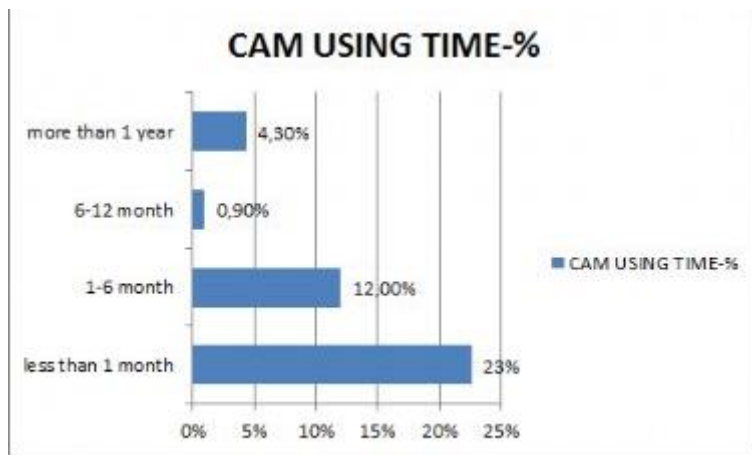

prescribe alternative and complementary therapies in Turkey.

CONCLUSION:

Use of alternative and complementary products were common in Diabetes Mellitus patients admitted to outpatient endocrinology clinics. Healthcare professionals should be aware of complementary and alternative therapies and should keep in mind that they have the responsibility of informing their patients about these therapies during daily practice.

Keywords: complementary and alternative treatment; diabetes mellitus; patient.

¹Department of family medicine, Okmeydanı research hospital, İstanbul, Turkey

²Department of psychiatry, Okmeydanı research hospital, İstanbul, Turkey

Background&AIM: Depression and loneliness feelings are mostly unnoticed conditions that affect people's quality of life if untreated. Working at the trend level of loneliness and depression of the way of life in the elderly, thus evaluating their effects on social life, we aimed to investigate the relationship between sociodemographic characteristics.

METHOD: The study was performed on elderly people being nursed, living alone at home, and living with his family at home (with his wife, his children and children with his wife, or both), and 65 years and older individuals were selected. The nursery section of the study was selected from the elderly in 'İstanbul Darülaceze Kurumu' on voluntary basis. The ones living alone were selected from the people applied to the polyclinics in Okmeydanı Eğitim Araştırma Hastanesi. Data was obtained as the result of the survey done with Geriatric Depression Scale, UCLA-S Loneliness Inventory.

RESULTS: Rate of depression in elderly people is higher than the depression level in entire society. In correlation with depression, the same is true for the sense of loneliness. The sense of loneliness becomes more fierce, as depression becomes stronger. The elderly people living alone are more exposed to depression compared to the ones living with family or being nursed, and sense of loneliness becomes a more important problem for such people. The ones having a habit, liking to communicate with other people, enjoying family and friend visits, spending time with grandchildren (if any), in a nutshell the ones being easily socialized suffer less from the sense of loneliness.

CONCLUSION: To include the quality of life in geriatric population; we should know the affects of lifestyle and

their environment to their state of mind and loneliness feelings, as a family physician it is required to give health care for troubleshooting the negative affects of these.

Are there any differences in the trends of home visits between rural and urban regions in Croatia: 1995-2013

Hida Javoric

Family Practice "Dr. Hida Javorić, Foundation for the Development of Family Medicine in Croatia

Background and aims

Similar to other countries, home visits in Croatia are within the scope of family practice (FP). A study aimed to determine the overall trends in home visiting in Croatian FM demonstrated that the annual number of home visits is relatively small, whether it is viewed per patient (0.1) or per doctor (160) with a decreased trend. The aim of this study was to investigate if there are any differences in the trends of home visiting between Croatian rural and urban regions.

Method

The study is observational, population and longitudinal, from 1995 to 2013. A data sources were Croatian Health Service Yearbooks. The numbers of family doctors and the number of home visits were collected for each study year and in relations to rural/urban regions. According to the Strategy of Rural Development, Croatia is divided on three regions: rural, semi-rural and urban, containing almost the similar number of inhabitants.

Results

The results indicate that there are differences in the number of home visits in relations to urban and rural regions. The biggest number of them was found in rural regions, then in semi-rural and in urban regions. For instance in 2000 when the number of home visits was higher; it was performed 0.16 home visits per patient in rural, 0.14 in semi-rural and 0.10 home visits per patients in urban regions. In the same year, each family doctor working in rural areas performed 189 home visits, in comparison to 174 in semi-rural and 122 in urban regions. The differences in the trends were not found, the number of home visits increased until 2000 and then decreased in all regions.

Conclusions

A higher number of home visits was found in Croatian rural then in semi-rural and urban regions, with decreased trends in all regions.

Keywords: visits, family practice, rural/urban differences, Croatia

Trends in average anual number of home visits in Croatian Family Practice, 1995-2014

A great number of home visits are found in rural regions, then in semi-rural and in urban regions. The differences in the trends are not found (Fig 2).

Trends in average annual numbers of home visits performed in Family Practice regarding the rural, semirural and urban regions of Croatia, 1995-2014

In 2000, it was performed 0.16 home visits per patient in semi-rural, 0.14 in rural and 0.10 home visits per patients in urban regions. In 2014 it was performed 0.11 home visits per patient in rural, 0.12 in semi-rural and 0.06 home visits per patient in urban regions.

Trends in average numbers of home visits per one patients performed in Family Practice regarding the rural, semirural and urban regions of Croatia, 1995-2014

In 2000, each family doctor working in rural areas performed 189 home visits, in comparison to 178 in semi-rural and 120 in urban regions. In 2014 it was performed 159 home visits per one family doctor in rural regions, 162 in semi-rural and 105 in urban regions.

Trends in average annual numbers of home visits per one family doctor regarding the rural, semirural and urban regions of Croatia, 1995-2014

⁷Department of Child Development and Family Studies, Institute of Human Ecology, Seoul National University, Seoul, Korea

Background

Appropriate Family function is important to maintain a sound health in individuals. Depression is one of representative disease known to be affected by family function. But, in Korea, among the parameters evaluating family function, family communication has received little attention in the depression studies. In this study, we aimed to examine whether family function, which was evaluated by two distinct parameters – family type, and family communication, is related with depressive symptoms in an individual.

Methods

From April 2009 to June 2011, 520 couples (1,040 patients) were investigated with Family Cohort Questionnaire; 697 subjects who fulfilled all of questionnaire for family function, and CES-D for depressive symptoms were included in the analysis. For family function, Circumplex model in FACE-III (family type) and FCS in FACE-IV (family communication) were used.

Results

Among the subjects, 309 (44.3%) reported depressive symptoms. In multivariate logistic regression analysis for the risk factors of depressive symptoms, which adjusted with age and other significant factors in univariate logistic regression analysis (income and AUDIT-K score for men, none for women), family-type did not reveal any significant association with depressive symptoms, whereas high-level of family communication was associated with low incidence of depressive symptoms for both men and women (OR 0.312, 95% CI 0.158-0.618 in men, OR 0.361, 95% CI 0.214-0.609 in women).

Conclusion

Low-level of family communication may be a risk factor for depressive symptoms of an individual. Evaluating family communication can be useful in assessing the depression risk.

The prevalence of internet addiction in eight-grade students in Canakkale, Turkey

Yusuf Haydar Ertekin¹, Aysegul Uludag¹, Murat Tekin¹, Sibel Cevizci², Erkan Melih Sahin¹

¹Department of Family Medicine, Canakkale Onsekiz Mart University, Canakkale, Turkey

²Department of Public Health, Canakkale Onsekiz Mart University, Turkey

AIM

We aimed to investigate the prevalence of internet addiction in last grade students in secondary schools.

METHOD

Three of the secondary school located in the center of Çanakkale were selected by cluster sampling method. The study was carried out with all last grade secondary school students in the sample. Turkish version of Young's Internet Addiction Scale(YAS) was administered to students. Addiction levels was classified as "non-addiction", "possible addiction" and "addiction".

RESULTS are in Table 1.

CONCLUSION

Internet addiction of students in the eighth grade is not as high as expected. We suspect that internet addiction was to be shifted to smartphone addiction which can access to the internet.

Keywords: Internet Addiction, Prevalence, Adolescent

pain management and follow in primary care: do we resolve?

Izaskun Odriozola, Junec Gonzalez, Nerea De Sousa, Flor Insua, Pedro Iturrioz, Enrique Perez De Ayala
Basque Health Service

Background & AIM:

- Know characteristics of pain and its management in Primary Care (PC).
- Assess treatment and the degree of resolution of pain in this area.

Design: Cross sectional study with follow-up.

Setting: Patients attending consultations with pain in 3 health centers PC for a month in the Gipuzkoa province (Basque Country): Irun Centre, Irun Dumboa and Beraún.

METHOD: We used convenience sampling. Inclusion criteria were being ≥ 14 years and presenting acute or chronic pain (≥ 3 months). Exclusion criteria were patients who refused to cooperate, or who had cancer pain moderate-severe cognitive impairment with communication difficulties.

Information was collected on demographics (name, age, sex and employment activity), clinical data (reason for consultation, duration, type, location, etiology and pain intensity (measured by Oral Scale Analog Pain (OSAP)), therapeutic data (type of treatment, type of pharmacological treatment prescribed pain scale according to WHO and whether or not the bypass) and monitoring data (resolution of pain with VAS, side effects and overall patient satisfaction).

Monitoring is conducted through a telephone interview at 15 days of inclusion in the study. Were considered missing follow-up study of patients who have not responded to 3 phone calls.

RESULTS: Initially 87 patients, of whom 68 were followed (78.2%) were included.

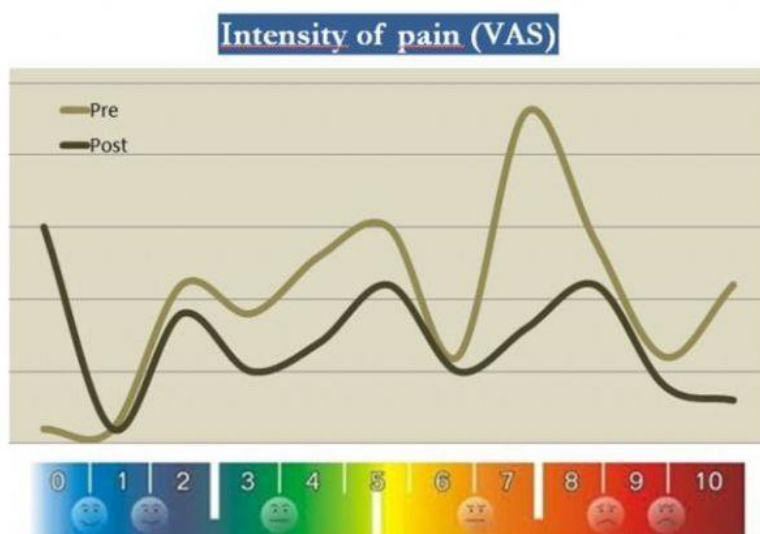

- The average age was 57 years, most women (63-/72%) and inactive occupationally (54/62%).
- The pain was assessed with OSAP ≥ 7 (46/87,49%). After 15 days of treatment, remained in that range OSAP (22/68,32%). The impact of the intervention has reduced pain intensity by 17% and resolved 20.5%.
- Side effects were presented (11/68,16%), usually digestive.
- Overall satisfaction is positive in (62/68,91%), being excellent in (17/68,25%).

CONCLUSIONS:

- The majority of patients who started treatment has positive results with few side effects.
- The PC is operative in pain management.

Colorektalcancer patients pathway from symptoms to diagnosis in northern Sweden

Catharina Ingvarsson, Mikael Lilja

Department of public health and clinical medicine, family medicine Umeå university

BACKGROUND: Colorectal cancer (CRC) is the third most common cancer in Sweden. Primary care is often the first instance for patients with onset of cancer. A delayed diagnosis may affect disease prognosis. Few studies describe delay of cancer diagnosis linked to rural living or psychosocial situation.

AIM: To describe delay in the diagnosis of CRC.

Questions: Is time from the first visit in primary care to diagnosis affected by rural living, the patient's age, gender, or co-morbidity, in the year ahead of diagnosis?

METHODS: Two years retrospective analysis of medical records for all patients (n = 498) with CRC 2012 in three sparsely populated counties in northern Sweden, (together 600,000 inhabitants and 7 hospital at an area equal to Greece). The patients distance to the nearest hospital (≤ 30 km, 31-100 km, > 100 km) calculated with Google maps was used as a proxy for rural living. Patients were age grouped (≤ 60 , 61-70, 71-80 and > 80 years), and ASA groups were used to describe co-morbidity, comparing ASA 1 (healthy) to ASA 2-5. Median analyzes was used for the statistics.

RESULTS: 75% of all patients with CRC first attended primary healthcare. 81% of those were referred to hospital after one or two visits with a median time of 15 days. The median time from first visit in primary care to clinical diagnosis was for men and women 43 and 61 days respectively ($p = 0.005$). For ASA groups, age groups or for rural living, no difference in time to clinical diagnosis was seen.

CONCLUSION: Our results show that female sex, but not rural living is linked to a delayed CRC diagnosis. Further analysis of the collected data is ongoing.

Background. Compliance to medications is an important issue when managing chronic illnesses. Patient noncompliance may contribute to poor blood pressure control

OBJECTIVES: To determine the prevalence of compliance among treated hypertensive patients in Sarawak, and its association with their sociodemographic and medical characteristics.

METHODS: This is a cross sectional study done in government primary health care clinics in Sarawak involving 25 Health Clinics with doctors and 10 Outpatient Departments in the district hospitals. Systematic random sampling was used. Hypertensive patients' socio demographics, medical data and physical examination findings were recorded. Their compliance to medication was assessed using Morisky Medications Adherence Scale Bahasa Melayu Version (MMAS-BM).

RESULTS: 2289 respondents were involved with mean age of 56.2±11.3 years.

Majority were females (65.9%), predominantly Iban ethnicity (43.1%). and completed secondary education (42.2%). Almost half were housewives (40%) and majority had household income below RM2000 (76.3%). Half respondents stayed in the rural areas, 79.2% come to clinic using their own transportation taking less than 20 minutes to reach (60%) and spent less than RM 10 for the journey. More than half of the respondents do not exercise (56.2%), 15% are smokers and 14.7% consume alcohol at least once a month. Forty-two percent had hypertension ≤5 years, 1/3 had diabetes, 55.4% had dyslipidaemia and 4.1% has IHD.

Difficult transportations to clinics, smokers, alcohol consumption and dependence on supervised medication intake were predictors of poor compliance. Presence of other concomitant diseases including diabetes, and regular exercise are predictors of good compliance.

CONCLUSION: Prevalence of poor compliance among treated hypertensive outpatient in Sarawak is 29.3%. Predictors for poor compliance were difficult transportation, smokers, alcohol consumption and dependence on others for supervised medication, while predictors for good compliance are presence of other concomitant diseases, suffering from more diseases and regular exercise.

No exercise	0.66	0.54-0.81	0.00	
≥ 30 mins				
Duration of hypertension				
≤ 10 years				0.50
11-20 years				
Antihypertensives				
Calcium channel blocker	1.22	1.10- 1.47	0.04	
alpha blocker	2.75	1.14 - 5.63	0.02	

High BMI, female gender, higher income, smoking, alcohol consumption and treatment with calcium channel blockers and alpha blockers were found significantly associated with poor compliance. Exercise, longer duration of hypertension, and unemployment were factors significantly associated with good compliance.

Multivariable regression analysis for factors affecting non-compliance

Variable	Odd's Ratio	95% CI	p-value
Alcohol	1		
Nil	1.52	1.07-2.16	0.01
≤ 1/month	2.28	1.30-4.00	0.04
≥ 2/month			
Exercise	1		
Nil	0.79	0.62-1.00	0.05
>30 minutes			
Duration of HPT	1		
<10 years	0.61	0.39-0.96	0.03
≥10-20 years	0.46	0.25-0.86	0.01
≥ 20 years			
Transport	1		
Own	2.1	1.13-3.95	0.02
Boats			

Multivariable analysis found that alcohol consumption, and difficult transportation were significant independent predictors of poor compliance to treatment while exercise and longer duration of hypertension were significant independent factors of good compliance among treated hypertensives in Sarawak.

Skin disorders in Croatian Primary Health Care: a longitudinal study, 1995-2013

Vesna Tabak¹, Branka Zivkovic Duvnjak², Damir Tabak³

¹Vesna Tabak, Family Practice „Dr. Vesna Tabak“, Zagreb, Croatia

²Branka Zivkovic, Family Practice „Dr. Branka Zivkovic-Duvnjak“, Silba, Zadar, Croatia

³Damir Tabak, University of Zagreb, School of Medicine, Zagreb, Croatia

Background & aims

The evidence usually showed that around 50% of people reported a skin problem in the preceding 12 months and with around a quarter of them considered worthy of medical care. In Croatia, there are almost no studies investigating the skin problems seen in primary health care (PHC), especially no longitudinal studies. The main aim of this study was to investigate nineteen-years trends in skin disorders registered in Croatian PHC.

Methods

The study is observational and retrospective, based on routinely collected data from PHC, yearly published in the Croatian Health Service Yearbooks, 1995 - 2013. The morbidity data were registered based on the International Disease Classification, version X, for skin disorders labelled as L00-L99. Recorded diagnoses are shown in the leading categories of diseases and only some are shown separately. Morbidity is registered according to the patient's age group: 0-6 years, 7-19 years, 20-64 years and 65+ years.

Results

During the observed period, skin diagnoses registered in PHC increased in two-folds, from 420.293 diagnoses in 1995 to 757.832 diagnoses registered in 2011 when it was the highest. The skin disorders increased mostly among elderly people. The increase is especially sharp after 2008 when e-medical records and registration was introduced. The less increase is observed in skin infections, even decreased among pre-school children is found, than diagnoses of dermatitis, increase is found again mostly among elderly. The disorders labelled as others increased mostly, and among elderly for a more than three times. At the same time, the number of dermatological consultations (need referrals) increased in 2.3 times.

Conclusions

The skin disorders registered in Croatian FP show increased trend, but the number of the dermatological consultations increased even more. The question is whether the PHC doctors are educated and equipped to face a problem of skin disorders.

Randomized, Placebo-Controlled, Double-Blind, Multi-Center, Clinical Study to Evaluate the Efficacy of Zerex in

Female Young Adult with Fatigue

Whan Seok Choi, Na Eun Choi, Sang Ah Youn, Sun Myeong Ock, Jun Seung Rho, Churl Min Kim

Department of Familymedicine, The Catholic University of Korea

BACKGROUND: The purpose of this study was to evaluate the effect and the safety of Zerex(was mainly composed Seanol) treatment for 4 weeks on fatigue in female young adults.

METHODS: This was a 4-week parallel-group, double-blind, randomized, placebo-controlled trial. This was a 4-week trial consisting of 3 visits. A total of 87 participants were randomized to either Zerex (n=58) group or the placebo group (n=29). Subjects were administered with 3 capsules of Zerex or placebo 3 times a day. FSS(fatigue severity scale), concentration scale (reading and listening) were measured at baseline (visit 2) and at 4-week (visit 3).

RESULT: In Zerex group, mean change of FSS at the end of 4 week compared to baseline period decreased by 1.05 ± 1.10 , in placebo group, whose mean change decreased by 1.17 ± 0.98 . No statistically significant difference was observed between Zerex group and placebo group. In secondary efficacy variable, concentration scale (reading and listening), significant reduction was observed. In Zerex group, mean change of concentration scale at the end of 4 week compared to baseline period decreased by 0.48 ± 0.67 , in placebo group, whose mean change decreased by 0.16 ± 0.60 .(Wilcoxon rank sum test; $p=0.0141$) No adverse event was reported in either group.

CONCLUSION: In female young adults, 4-week treatment with Zerex 9 capsules a day was associated with the improvement of concentration (based on increase in concentration scale). Zerex demonstrated an acceptable safety profile and was generally well tolerated.

The Effect of Relaxation Training Program on Autonomic Nervous System

Whan Seok Choi, Kyoung Rak Kim, Sang Ah Youn, Churl Min Kim
Department of Family Medicine, The Catholic University of Korea

BACKGROUND: In modern society, stress is one of the most significant problems affecting physical as well as mental health. Long-term exposure to severe stress results in an imbalance of autonomic nervous system and develops various mental and physical diseases. In recent, various stress managements have been identified and they are commonly including relaxation components. The purpose of this study was to investigate the effect of relaxation training program invented by authors on autonomic nervous system.

METHODS: We investigated 21 adult patients with decreased autonomic function (RMSSD value under 20ms). Subjects were randomized into two groups, Receiving (1) Relaxation training program or (2) Relaxation training program except relaxation component (control); twice a day for two weeks. The values of Heart rate variability, Perceived Stress Scale, Beck Depression Inventory, Blood pressure were assessed before, at the end of the two-week training. Data were analyzed using t-test for subject homogeneity verification and paired t-test to examine the hypotheses.

RESULTS: After training, the experimental group had significantly higher values for SDNN ($P=0.036$), RMSSD ($P=0.031$), TP ($P=0.042$), and HF ($P=0.048$) compared to the control group. Both training group and control group showed decrease after 2 week training in Perceived Stress Scale, Beck Depression Inventory which was not significant. Both training group and control group showed decrease after 2 week training in Blood pressure, only systolic blood pressure ($P=0.047$) was significant.

CONCLUSIONS: We found the relaxation training program improved overall autonomic function and induced sympathovagal balance towards parasympathetic activity. Therefore we suggest the relaxation training program invented by authors is useful tool for stress management.

Labour productivity loss because of Irritable Bowel Syndrome complaints

Carla E Flik¹, Wijnand Laan¹, André Pm Smout², Niek J De Wit¹

¹Julius Centre for Health Sciences and Primary Care, University Medical Centre, Utrecht, the Netherlands

²Department of Gastroenterology and Hepatology, Academic Medical Centre, Amsterdam, the Netherlands

Introduction

When calculating indirect costs for IBS most researchers only take the costs for loss of labour days into account.

Aim

To report the combined number of sick leave days and the loss of efficiency during the days IBS patients did work.

Method

207 adult IBS- patients, meeting Rome III criteria were selected. The impact of IBS on absenteeism from work < two weeks and > than two weeks, if one was hindered by IBS complaints when working in the past two weeks and how efficient one has worked, was measured.

Results

Of the 140 working IBS patients, 19 (18.2%) of 104 female were absent from work because of IBS complaints, 10 (9.6%) < two weeks, 9 (8.7%) > two weeks; of the 36 male IBS patients 5 (13.9%) were absent from work because of IBS complaints, 3 (8.3%) < two weeks, 2 (5.6%) > two weeks. In 20% of the female and 7% of the male patients, IBS complaints had no impact on their labour productivity, respectively 64% and 23% were hindered to some extent and 16% of women and 23% of men were hindered very much; 33.3% of women and 52.8% of men worked

less efficient than normal because of their IBS complaints.

Conclusions

IBS complaints do not only result in substantial absenteeism from work, but also in severe loss of efficiency among those IBS patients who do not report sick, but continue working. When quantifying disease-related loss of labour productivity both aspects should be taken into account.

Severity of symptoms and psychological factors as predictors of quality of life of patients with Irritable Bowel Syndrome

Carla E Flik¹, Wijnand Laan¹, André Pm Smout², Niek J De Wit¹

¹Julius Centre, Health Sciences and Primary Care, University Medical Centre, Utrecht, the Netherlands

²Department of Gastroenterology and Hepatology, Academic Medical Centre, Amsterdam, the Netherlands

Introduction

The relative impact of psychological distress and severity of abdominal symptoms on health related quality of life (HRQOL) and their interaction is important to focus IBS treatment.

Aim

To investigate the impact of symptom severity and the psychological variables anxiety, depression and somatization on HRQOL in patients with IBS.

Methods

A total of 207 adult patients, meeting Rome III criteria for IBS, recruited in primary and secondary care, were analyzed. Severity of symptoms (IBS-SSS), anxiety, depression, somatization and overall psychoneuroticism (Symptom Checklist (SCL-90)) and health related quality of life (IBS-Qol, ranging from 0-100) were measured and analyzed using linear regression models.

Results

Results of 193 (93%) patients were available for analysis. Symptom severity accounted for 20% of the Qol overall score; 38% of the variation in IBS-Qol was explained by the SCL-90 overall score. The higher the scores, the higher the impact. For the subscales anxiety, depression and somatization these figures were 26%, 30% and 22%, respectively. Combined they accounted for 50% of the variance in IBS-Qol.

Conclusions

Patients with more severe IBS symptoms experience more impact on their quality of life. The same applies to increasing psychological problems, with the highest impact of depression. The overall impact of psychological factors on HRQOL is stronger than that of symptom severity.

As both symptom severity and psychological variables are independent contributors to quality of life in IBS, both factors should be addressed in treatment.

The association of blood lead level and high-density lipoprotein is modified by Metallothionein 2A polymorphisms, rs10636 GC and rs28366003 AA genetic combination

Chen Cheng Yang¹, Chen Cheng Yang², Chen Cheng Yang³, Hung Yi Chuang³, Hung Yi Chuang⁴

¹Department of Family Medicine, Kaohsiung Municipal Cijin Hospital, Kaohsiung, Taiwan

²Community Health Promotion Center, Kaohsiung Municipal Cijin Hospital, Kaohsiung, Taiwan

³Department of Family Medicine, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan

⁴Department of Public Health, Kaohsiung Medical University, Kaohsiung, Taiwan

Background and Aim

Lead is broadly concerned issue in worldwide. It causes damages of multiple organs and has certain influence on lipid metabolism. Metallothioneins(MTs) are low molecular weight, cysteine rich, metal binding proteins, which play important role on metal detoxification. MT2A gene, one of common expressive MTs gene, has effect on lead metabolism, but rare studies about the associations between MT2A polymorphisms and lipid metabolism in occupational lead exposure. Therefore, our purpose is to investigate the association of blood lead level and lipid profile in chronic lead exposed participants, and whether the association is influenced by the polymorphisms of MT2A gene.

Methods

We recruited 677 participants after informed consents were obtained. All the samples were collected and analyzed for lipid biomarkers, blood lead levels, genotyping of MT2A polymorphisms and liver function tests, including alanine aminotransferase (ALT) and aspartate aminotransferase (AST). Moreover, a short questionnaire inquiring about medical history, alcohol drinking and cigarette consumption of the subjects was part of the examination. The data was dealt with IBM-SPSS version 19 statistical software for descriptive analyses and linear regression model.

Results

The investigation revealed lead toxicity had effects on Low-Density Lipoprotein (LDL) increasing and High-Density Lipoprotein (HDL) decreasing by general linear model, predicted by blood lead, MT2A combination and other potential factors. Meanwhile, the rs10636 GC * rs28366003 AA genetic combination had a protective influence on HDL, even under lead exposure.

Conclusion

In conclusion, the association of blood lead level and HDL is modified by Metallothionein 2A genetic combination. That is rs10636 GC and rs28366003 AA genetic combination in MT2A SNPs play a protective role on HDL, although lead toxicity has a harmful effect on HDL in human being.

⁴Riga Stradins University, Department of Human Physiology and Biochemistry, Riga, Latvia

⁵Latvia University, Institute of Experimental and Clinical Medicine, Riga, Latvia

⁶Riga Stradins University, Department of Internal Diseases, Riga, Latvia

BACKGROUND: It is essential for a family physician to select people who would need immediate lifestyle changes to prevent a disease. There is evidence that fatty liver and omentin is related to cardiovascular diseases risks, however, there is still a gap of knowledge regarding omentin as an early marker of increased risk of hepatic steatosis and cardiovascular disease.

AIM: To find out if there is a difference between omentin levels in people with and without hepatic steatosis

METHODS: A trans-sectional study in Riga, Latvia included 92 clinically healthy individuals having body mass index (BMI) above 25 m²/kg and below 40 m²/kg and in age group 30-45 that visited primary care physician. Individuals underwent CT scan for signs of hepatic steatosis and were divided in two groups: individuals with and without any signs of fatty liver. All individuals were tested for omentin levels using enzyme-linked immunosorbent assay (ELISA) test. Independent samples t test was employed to compare the means of the two groups.

RESULTS: We observed that individuals with no signs of fatty liver had higher omentin levels (124,6±74,5 ng/ml; n=56) than those having signs of fatty liver (99,3±51,9 ng/ml; n=36). This difference (25,4±13,2 ng/ml, 95% CI [0,085, 51,62] was not significant t(89,3)=1,92; p=0,058.

CONCLUSIONS: For individuals residing in Riga, Latvia presence of omentin level alone cannot be considered as an indicator of fatty liver and its related cardiovascular diseases risk. More research has to be done to find out more precise indicators.

Palliative & End of Life Care

Iva Lopes¹, Filipa Faria², Ana Catarina Pires³, Ana Luisa Pires³, Joana Leça⁴

¹UCSP de Macedo de Cavaleiros

²UCSP de Mirandela II

³UCSP Santa Maria II - Bragança

⁴USF Terras do Ave

BACKGROUND & AIM: The aging population and the provision of end of life care is being a challenge for the family physicians. The purpose of this research is to understand the reality of referrals to a Palliative Care Unit in the north of Portugal, to evaluate the ability to receive patients and their families and also assess the use of ambulatory structures to help patients in palliative phase.

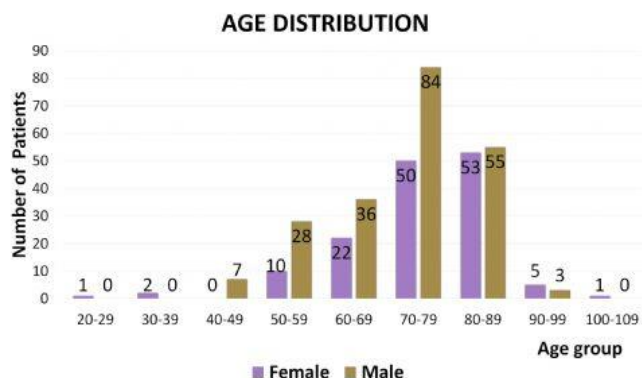

METHOD: Observational, descriptive and retrospective study involving a sample of patients of a Palliative Care Unit, admitted between January 2010 and June 2014. Data collection was conducted in August 2014 by SClinico[®] and treating data carried via Microsoft Excel 2013[®].

RESULTS: 357 patients were included, 60% of whom were male. The average age was 73 years, and the average hospitalisation time was 32 days. It was found that 97% of the diagnoses were oncological, and the most common cancers were lung and gastric. On admission, the majority of patients had a Palliative Performance Scale of 30%. The majority of the referrals (87%) were made by a hospital service. Although half of the patients referred through the Primary Health Care, had had prior home clinical assistance by teams of palliative care. The vast majority (89%) of admissions resulted in hospital death, but in the other cases (11%) it was possible to discharge patients. From these, 48% were able to return home, and the rest were sent to nursing homes and other types of institutions.

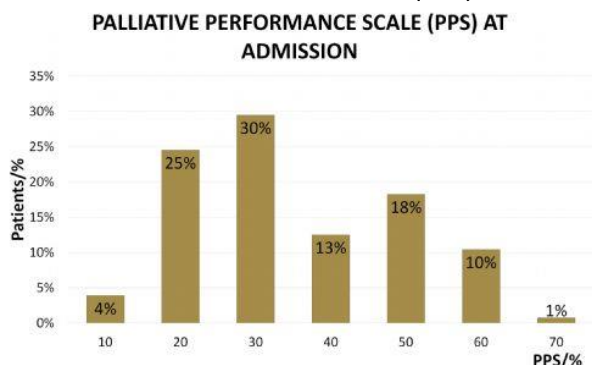

CONCLUSIONS: There is solid evidence that the involvement of family doctors in palliative care is an important factor to allow death at home, the preferred location for most Europeans.. It becomes imperative to invest in medical training and provide resources for the family physicians to be able to offer quality care at the end of life to their patients.

"Contraceptive methods used by 40 years and older women who applied Haseki Training and Research Hospital, Family Planning Unit"

Nazmiye Mehtap Hatunkız, Seçil Arıca

Department of Family Medicine, Haseki Training and Research Hospital, Istanbul, Turkey

Background & AIM: 40 years and older women's pregnancy rates decreased on with age. But these women fertilities continue. For this they need to use contraceptive methods. We try to detect usage frequency and continuing rate of several contraceptive methods chosen by 40 years and older women.

METHOD: A total of 398 40 years and older women who applied to family planning unit of our hospital for contraception in between January 2014 and December 2014 were analyzed retrospectively. We scanned that these women's age, education level, number of pregnancies, abortions, how the results the last pregnancy, recent pregnancy intervals those performed on an outpatient admission.

RESULTS: Mean age of the women was $44,1 \pm 3,4$. Women's age was maximum 53. The most common used contraceptive methods were copper IUD (%53,8) and condom (%14,8). Koitus interruptus was %13, Depo medroxyprogesterone acetate (DMPA) was %12,5. The highest continuation rate was for DMPA. Five of women didn't use any contraceptive methods. The average duration of last used method was $4,5 \pm 3,9$ years. The most common cause of outpatient visits were control of IUD (41.3 %) Maximum continuous DMPA (87.8 %) and the IUD (78.7 %), respectively.

CONCLUSION: To be protected from unwanted pregnancies of women 40 years and older period is a period in which they need to appropriate and effective contraceptive method. Women in this particular period, should receive counseling help from a health professional can assess the benefits and risks associated with that method when selecting available contraceptive methods.

Barrier contraception and IUD are suggested method for 40 years and older women %79,4 of these women applying family planning unit of our hospital had chosen these methods. There is needed to further studies investigating the factors influence on the preparation of contraceptive methods of 40 years and older women.

Level of Knowledge Regarding Insulin Therapy and Factors that Hinder Insulin Usage in Diabetic Patients

Ahmet Yilmaz¹, Faruk Kılınc², Abdullah Cim³, Muharrem Ak⁴

¹Dicle University Medicine Faculty Departments of Family Medicine

²Dicle University Medicine Faculty Departments of Endocrinology

³Dicle University Medicine Faculty Department of Genetics

⁴Zirve University Medicine Faculty Departments of Family Medicine

Diabetes Mellitus (DM) is a metabolic disorder characterized by insulin insensitivity and insulin resistance resulting in ineffectiveness and inefficiency of insulin in tissues. At this stage, the patients, whose HbA1C level is above 7.4, need to use insulin to achieve the blood glucose level indicated by American Diabetes Association. However, some patients may express reluctance or resistance to use insulin, and the treatment may be interrupted. We aimed to determine the factors that hinder the use of insulin in diabetic patients. A survey, consist of two sections, was performed based on theoretical knowledge about DM and insulin treatment. Totally 94 patients were participated to this survey whose HbA1c level was $\geq 7.4\%$. The sociodemographic features including age, gender, occupation, address and education level were registered. The data were analysed and frequencies were calculated using SPSS 18.0 Chi square and Spearman correlation tests were used, and P values and 95% confidence interval were calculated. $P < 0.05$ was accepted statistically significant. The mean age of the patients was $50,41 \pm 11,42$. The ratio of patients who believe the insulin usage worsen the disease was 19.2%, and who do not believe this idea was 33%. The 59.6% of the patients expressed that their religious beliefs were not against the use of insulin, and these patients also thought that it was a useful drug for DM treatment. Discussion It was observed that the patients, who do not use insulin (although they have to use it), did not have sufficient information on the effects of drugs. When we consider the mortality and morbidity of the DM, patients and their relatives must be provided sufficient information and guidance on the treatment of the disease by the health centre workers or the associated higher administrative authorities. If necessary, the use of insulin must be emphasized and the patients' blood glucose must be regulated

³Mid-West Specialist Training Scheme in General Practice

INTRODUCTION:

According to WHO primary care should be accessible, acceptable and available to all people equally. There are policy imperatives to include patients in the planning of primary healthcare initiatives. However, some groups have more difficulty in accessing primary healthcare than others and their voice is absent from planning processes. The aim of this study was to consult with marginalised groups to explore their experiences of accessing primary healthcare and identify their priorities for the delivery of care.

METHODS:

This qualitative study used participatory learning and action (PLA) methods. Using purposeful sampling we recruited members of marginalised groups in an urban area who were known to have difficulty accessing primary healthcare (n=11). We ran two focus groups with each marginalised group; initially to brainstorm experiences of accessing primary healthcare, and then to concentrate on ranking solutions in order of priority for attention by service planners. Data were co-analysed by researchers and participants following principles of inductive thematic analysis. Data from all six focus groups were examined by the research team for overarching themes.

RESULTS:

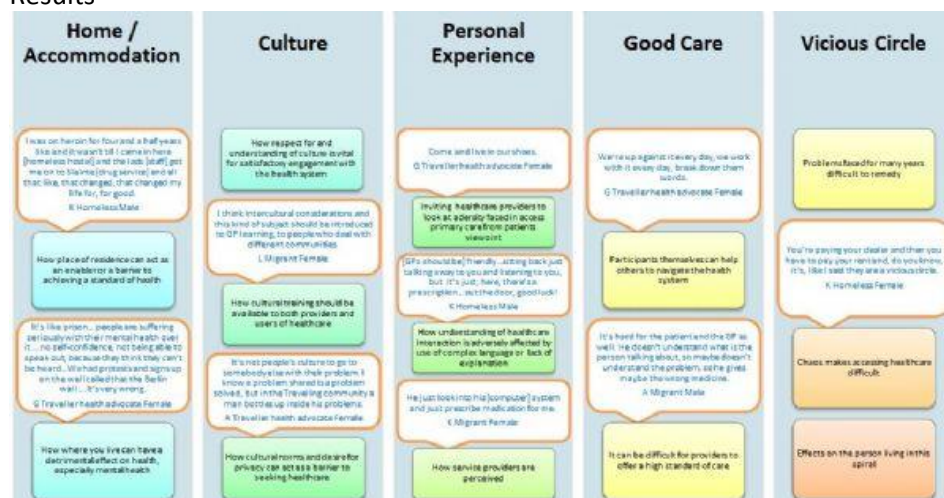

Five overarching themes were documented: (i) home/accommodation, (ii) culture, (iii) personal experience, (iv) good care and (v) vicious circle. Many of these themes describe issues around the social determinants of health including how personal mental health and societal discrimination can be barriers to healthcare. The importance of communication and building trust with healthcare providers was discussed, as negative experiences can deter seeking care. The concept of a vicious circle of ill health, personal chaos and barriers to access was also uncovered.

CONCLUSIONS:

PLA is a valuable method for supporting participants whose voices are absent from planning healthcare to identify priorities for their healthcare. Findings indicate the need for solutions to complex personal and structural problems that create barriers to healthcare for those who need it most.

Chronic Obstructive Pulmonary Disease – A View on a Medical Center

Maria Miguel Sá, Adriana Relvas, Ana Margarida Pinho, Ana Palhares Delgado, Ana Sofia Azenha, Celia Silva, Jacinta Vaz, Mara Silva, Nádia Correia, Sara Almeida, Tânia Dias
USF Famílias, ACeS Entre Douro e Vouga, Santa Maria da Feira, Portugal

Background & Aim

Chronic obstructive pulmonary disease (COPD) is an important cause of mortality and morbidity and in Portugal, most recent studies show a prevalence of 14.2%.

According with Global Initiative for Chronic Obstructive Lung Disease (GOLD) the diagnosis should be considered in individuals with symptoms and risk factors. The diagnostic confirmation is obtained with lung function tests. The proper guidance of these patients is a constant challenge in primary care services.

The goal of this study is to determine prevalence of COPD in the population of a Clinical Center called Unidade de Saúde Familiar (USF) Famílias. The objective also includes the characterization of those patients identified: diagnosis and therapeutical profile, disease duration, severity and risk of exacerbations.

Method

Descriptive transversal study involving a population of patients 40 years of age and over with the diagnosis of COPD (at December 31st 2013) in the referred Clinical Center. The data was collected from the electronic medical database. Variables selected were: gender, age, age at diagnosis, diagnosis criteria, airflow obstruction severity, risk of exacerbation, disease duration, suitable treatment and vigilance on primary care services.

Results

The prevalence of COPD in our Clinical Center was 4.3%, 68% of which were of male gender. In 93% of the patients the disease has duration under 10 years, and only 18% have the three major diagnosis criteria. The majority are at low risk for exacerbations.

As of what concerns to treatment, the long-duration bronchodilators and inhalators corticosteroids were most used.

Conclusions

The prevalence of COPD in USF Famílias is lower than the prevalence of this disease at a national level (4.3% versus 14.2%).

This analysis has helped to identify a problem related to an insufficient registering of data respecting symptom description, risk exposure, lung function test results and treatment.

Hypertension in adolescents

Albina Softic¹, Azijada Beganlic², Nadira Hodzic¹, Emina Hodzic¹, Sevko Sulejmanovic¹

¹Public Health Center Gracanica, Gracanica, Bosnia and Herzegovina

²Public Health Scientific Institution Tuzla and Educational Family Medicine Center Tuzla, Tuzla, Bosnia and Herzegovina

INTRODUCTION: Essential hypertension occurs in younger children, and with asthma takes is most common chronic disease of childhood. One of the factors that contributes to increase in blood pressure is a global epidemic of obesity in children and adults. This is a growing problem world wide.

OBJECTIVE: The aim of this study was to determine the prevalence of hypertension and prehypertension in young adulthood in adolescents aged 15-17 years in the area of Tuzla Canton.

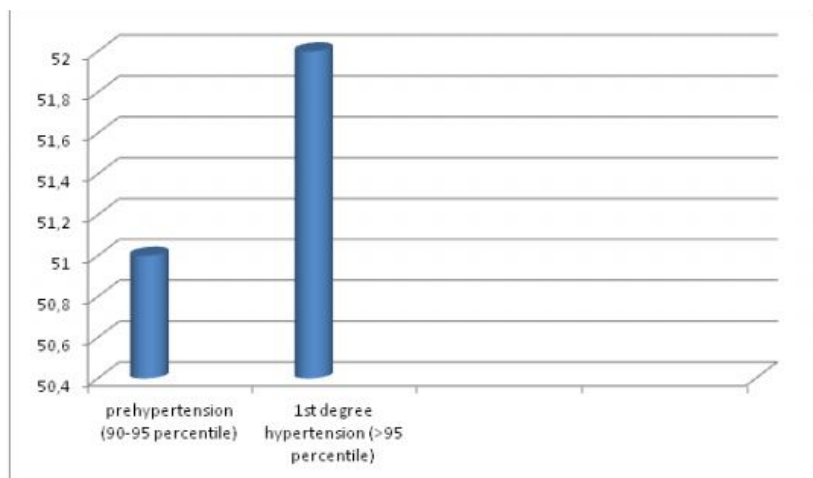

METHODS: We conducted a prospective clinical study to evaluate the prevalence of prehypertension and hypertension in a causal relationship with overweight and obesity in adolescents, students of first, second and third grades of high school. Hypertension in adolescents exists if the value of blood pressure above the 95 th percentile for age and height of an individual and prehypertension on the value of blood pressure, which is located between 90 th and 95 th percentile. All patients were performed by measuring blood pressure three times, not in the same day, in a sitting position, the first time on both upper arms, after at least 15 minutes. Respondents were determined BMI also.

RESULTS: A total of 103 802 (13%) of respondents have elevated blood pressure, 51 (6.4%) belong to the category of prehypertension in young adulthood and 52 (6.5%) first degree of hypertension category. Prehypertension more adolescents suffer with excessive BMI and obesity, 13% suffers prehypertension and hypertension 34% first degree in the categories of excessive BMI and obesity. Prehypertension among respondents with an ideal weight suffers 35 of 583 (6%), and hypertension and the level 17 of the remaining 548 (3%).

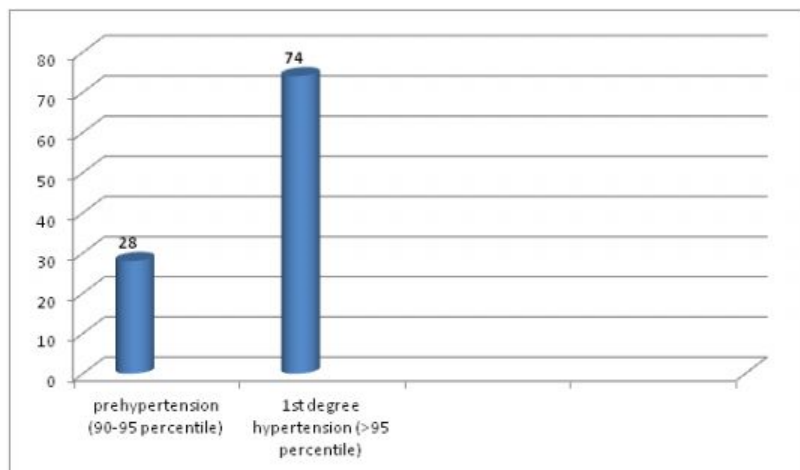

CONCLUSION: The prevalence of prehypertension and hypertension among adolescents in Tuzla Canton is very high. Overweight and obesity are risk factors for hypertension in adolescents.

Complications of diabetes mellitus type 2

Albina Softic¹, Azijada Beganlic², Nurka Pranjic³

¹Public Health Center Gracanica, Gracanica, Bosnia and Herzegovina

²Public Health Scientific Institution Tuzla and Educational Family Medicine Center Tuzla, Tuzla, Bosnia and Herzegovina

³University of Tuzla Medical Faculty, Tuzla, Bosnia and Herzegovina

BACKGROUND: Diabetes mellitus type 2 is one of the leading causes of morbidity and mortality in the world.

During the last decades diabetes mellitus typ 2 increasingly affects younger people, and it is a serious health's risk factor worldwide. Due to the complications of diabetes, it requires constant care for these patients.

OBJECTIVE: The aim of this study was to determine the frequency of complications of type 2 diabetes mellitus among patients who were treating in Family Medicine Department, Public Health Center Gracanica.

METHOD: A retrospective cross-sectional study was conducted on patients suffering from type 2 diabetes mellitus for more than five years. The following parameters, taken from their medical records were: age, sex, duration of disease, smoking status, BMI and complications: nephropathy, retinopathy, CAD (coronary arthery disease) and polyneuropathy.

RESULTS: Average age was 59.8 years. Average disease duration was 12.3 years. Of the total number of 50 respondents, number of respondents females were 45% and 55% males. Smokers were 37.5%, former smokers were 25% and non-smokers were 37%. Obese subjects were 47.5%, 32.5% overweight and normal body weight subjects 20%. Nephropathy had 62.5% of respondents, retinopathy had 82.5%, CAD 45% and 72.5% polyneuropathy.

CONCLUSIONS: Complications of type 2 diabetes mellitus in patients are highly frequent. Due to the average age of the patients can be concluded that these patients will have a significantly reduced quality of life in the future and be a huge burden to the health system. Significant efforts are needed in the primary prevention of type 2 diabetes mellitus for future generations, and prevention complications in patients with new diagnosis of diabetes.

Conversations of Exclusion

Austin O Carroll, David Wainwright, Derval Howley

Department of Health, University of Bath

Background & AIM: Homeless People have very poor morbidity and mortality profiles. We know that their usage of health service differs from that of the housed population and seems inappropriate and ineffective for caring for their health. This research sought to understand the Health Service Usage Behaviour of Homeless People in Dublin. This presentation relates to a barrier identified in that research which is a new concept called Conversations of Exclusion.

METHOD: A critical realist ethnographic approach was adopted and conducted in four sites frequented by homeless people in Dublin. This was supplemented by 37 semi-structured interviews with homeless people and 2 focus groups between homeless people and hospital doctors.

RESULTS: One of the factors identified in the research as contributing to the HSU pattern of homeless people were recurrent interactions between health professionals and patients whereby patients were either excluded or discouraged from attending the health service or self-excluded themselves from that or other such services. These interactions were described as Conversations of Exclusion. Four such conversations were described, the Benzodiazepine Conversation (where a patient asks for addictive medication); the Distrustful Conversation (where the doctor distrusts the patient); the Blaming Conversation (where the patient is blamed for their condition); and the Assertive Conversation (where the patients has not learnt to assert themselves in a manner that is not perceived as aggressive by the health provider).

CONCLUSIONS: These Conversations result in patients who are among the most unhealthy in society being excluded from health services. A technique for converting the Benzo Conversation into one of Inclusion will be presented. Conversations of Exclusion are one of the many barriers that exist for homeless people accessing such services.

Perceived benefits of mutual VdGM and Foundation for the Development of Family Medicine Exchange in Zagreb, Croatia?

Renata Pavlov¹, Süheyla Atalay²

¹Family Practice "Dr. Renata Pavlov", Zagreb, Croatia

²Department of Family Medicine, İstanbul Medeniyet University Göztepe Training and Research Hospital, İstanbul, Turkey

Background & Aims

In December 2014, Foundation for the Development of Family Medicine in Croatia and Vasco da Gama Movement organized 4-days exchange in Zagreb. 15 young doctors from 6 European countries took part. The program was divided in three parts. First, Croatian health care systems, family medicine (FM), medical education and quality improvement in FM were presented, followed by discussion on similarities and differences among countries. Two days were spent observing daily work of Croatian GPs in city and rural practices. Then, mini symposium was organised, Foundation's Days, where Croatians presented research works and colleagues system of FM in their respected countries. The aim of this survey was to evaluate effectiveness of Zagreb exchange program and to find out perceived benefits.

Methods

In this qualitative research, we asked participants to describe, in narrative way, benefits from the exchange program. 13 of 15 participants answered. Free-texts were analysed using thematic analysis method, first independently by three experts and than triangulated.

Results

Seven themes emerged from codes: 1. "My situation in relation to others", codes: same FM system; different types of FM residency; 2. "Organizational issues", codes: working in the shifts; e-recipes; 3. "Handling daily practice", codes: dealing with economic burden; combination of public and social health; 4. "Learning professionalism", codes: people who have faith and eager nothing is impossible; 5. "Personal growth", codes: I am not alone and I have a big family, 6. "Motivation for future work", codes: motivated me to start my own scientific project; 7. "Cultural issues", codes: hosts were so kind and sincere; home cuisine; unforgettable experience.

Conclusion

Results indicate that the exchange was effective and beneficial for participants, mostly because of getting broader view on FM and contributing to professional and personal growth.

Keywords: evaluation, exchange program, family medicine, VdGM, Croatia

Theme 1. My situation in relation to others - comparing and contrasting health care and GP/FM systems

Participants quotes – codes typical for the theme:

... “the same family medicine system...” “we share the same problems.....” all of us use similar practices and insights” ... “our GPs are very similar” “unlike the UK General Practice, in Croatia they use e-prescriptions.... “...not a big difference between Croatia and Turkey”..... “...patients have similar expectations”..... “We do not have anything like this” “different type of family medicine residency program“.... “Seeing different systems – I began to see our problems in a different window”.... “what exist out of my country”..

Theme 2. Organizational issues

Participants quotes – codes typical for the theme:

... “working in shifts can be beneficial for both sides, doctor and patients”.... “sharing same room by two doctors good”.... “good communication between primary care and secondary or tertiary hospitals”... “software used by Croatian GPs were more detailed for prescriptions, for example costs are included”... “such a PC system ...that you can see what has happened to your patient recently”.... “we also should change the method of payment for GPs, like in Croatia”.... “nurses who work just for home care were different than Turkey”.... “Croatia comprises private and state systems - often side by side...”

Theme 3. Handling daily practice

Participants quotes – codes typical for the theme:

.. “I’ve seen a skillful Croatian doctors in handling patients’ problems.... “recognized patient’s unique needs, such as posttraumatic-stress syndrome and demographic changes”... “I was impressed by the desire to combine such forward thinking in public and social health with daily practice” “I saw that patients had similar expectations” “how Family Physicians in Croatia deal with the economic burden”... “home visiting with Miro was interesting experience..”

Theme 4. Learning professionalism

Participants quotes – codes typical for the theme:

.. “I saw that for people who have faith and eager nothing is impossible”. “I was impressed by the motivation of GPs in Croatia to improve the recognition and academic credibility of GP as specialty”.... “how Family Physicians in Croatia deal with the getting their economic/social rights”.... “nothing to be achieved passively but needs investment in time, motivation and commitment by as family doctors”... “GP in Croatia are getting better position”... “the meeting with young GPs from other countries gives the opportunity to enlarge the net of our professional links”

Theme 5. Personal growth

Participants quotes – codes typical for the theme:

.. „I am not alone and I have a big FAMILY” “I’ve seen that retirement is not an end” ...
“exchange supported my enthusiasm””great experience to present my work life in English,
.....”this exchange help me to confirm the direction I want for my future”..

Theme 6. Motivation for future work

Participants quotes – codes typical for the theme:

.. “possibility to collaborate with colleagues with multi-centric research and/or professional projects” ... “working together, it is possible”.. “presentation of the research motivated me to start my own scientific project”... “presentation of the Foundation was really inspiring for my future”... “each exchange I took something or made me think, what could we change”.. “we got some inspiration from you”.....

Theme 7. Cultural issues

Participants quotes – codes typical for the theme:

... “people here are very kind, polite, friendly and always helpful” “home cuisine was unforgettable experience” “I’ve seen the banks open till late hours” “I thought long working hours could effect the employees' lives”..

Evaluation of the Predictive Index for osteoporosis as a clinical tool to identify at risk of osteoporosis in Korean men

Ji Hyun Moon, Lee Oh Kim, Hyeon Ju Kim, Mi Hee Kong

Department of Family Medicine, Jeju National University & Hospital, Jeju, South of Korea

Background & Aim

Indications for the bone mineral density (BMD) test to find osteoporosis in men less than 70 years has not yet been clarified. In a previous report, we proposed a Predictive Index for Osteoporosis (PIO) as a new index for identifying men who need to measure BMD. PIO was as useful as the osteoporosis self-assessment tool for Asian (OSTA) to identify candidates for the dual energy X-ray absorptiometry (DXA). But previous study had limitations about a single-center and small sample sized study. In this study, we evaluated usefulness of PIO using the nationally representative data of Korea National Health and Nutrition Examination Survey.

Methods

Participants measured BMD with DXA and calculated PIO with OSTA. Receiver operating characteristic analysis was used to obtain optimal cut-off points for PIO with OSTA and compare the predictability of osteoporosis between the two indexes.

Results

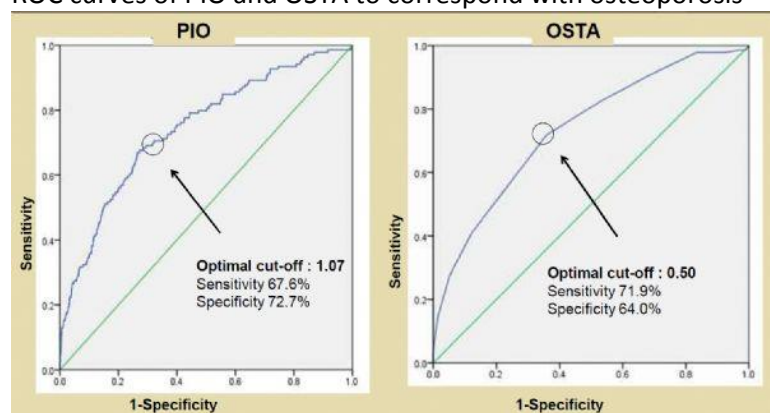

Both PIO and OSTA were useful clinical tools to identify a risk of osteoporosis in Korean men. The optimal cut-off value for PIO was 1.07, for which the sensitivity was 67.6%, the specificity was 72.7%, and the area under the curve (AUC) was 0.743. In the case of OSTA, using a cut-off point of 0.5, the sensitivity and specificity were 71.9% and 64.0%, respectively, and the AUC was 0.737.

Conclusions

The PIO was as useful as OSTA for screening index to identify candidates for the DXA in men aged 50-69 year.

Keywords: Osteoporosis, Predictive Index, Self-Assessment Tool

Should we wear a white coat in our practice? A cross-sectional study

Dagmar M Haller¹, Paul Sebo², François Herrmann³

¹Primary Care Unit, Faculty of Medicine, University of Geneva, Switzerland & Department of Community, Primary Care and Emergency Medicine & Department of Pediatrics, Geneva University Hospitals, Geneva, Switzerland

²Primary Care Unit, Faculty of Medicine, University of Geneva, Switzerland

³Geriatrics Division, Department of Internal Medicine, Rehabilitation and Geriatrics, Geneva University Hospitals, Geneva, Switzerland

Background and AIM: Previous studies show that patients prefer specialists and hospital-based physicians to wear white coats, but evidence from family practice is lacking. Our aim was to assess patients' preference for their family doctor to wear white coats.

METHODS: This cross-sectional study was conducted in Geneva, Switzerland. A random sample of 75 family doctors was contacted by post and 23 agreed to participate. In each practice, 50 to 100 consecutive patients coming to the practice for a scheduled consultation were invited to complete a survey about their expectations from the family doctor, including whether they preferred their doctor to wear a white coat or not. We examined the parameters associated with a preference for doctors wearing a white coat.

RESULTS: 1637 patients agreed to participate (participation rate: 97%, women: 63%, mean age: 64 years). Only 34% considered wearing a white coat as important. In multivariate analyses, older patients, those of Italian background (as opposed to Swiss origin), and patients consulting uncertified doctors and/or doctors wearing a white coat were more likely to consider white coats as being important.

CONCLUSIONS: These findings suggest that white coats are no longer considered a powerful symbol for a majority of patients in family practice. However, family doctors may wish to adjust their attire to meet the expectations of particular groups of patients.

Keywords: Patient expectations, White coat, Family practice, Health services research

Sleep Quality in Asthmatic Children

Bahadır Yazicioglu¹, Burcu Sezer¹, Sema Cetin Ayhan¹, Banu Gülcan Oksuz², Mahir Igde², Fusun Artiran Igde¹

¹Department of Family Medicine, Ondokuz Mayıs University, Samsun, Turkey

²Pediatric Clinic, Samsun Education and Research Hospital, Samsun, Turkey

AIM: Asthma is characterized with cough and dyspnea, especially rising at the late night hours. So asthmatic children mostly have low sleep quality and sleep disorders. We aimed to evaluate correlation between asthma and sleep quality.

METHODS: A cross-sectional study, was conducted between 15 February to 15 March 2014 at the Samsun Education and Research Hospital. 25 asthmatic children admitted to the pediatric allergy clinic and 25 children with non-asthma admitted to the general outpatient pediatric clinic selected with randomization for the study. Data are collected by pediatric sleep questionnaire (PSQ) which has developed by Dr. Ronald D. Chervin, and made Turkish validity and reliability by Pinar Oner et al. Pediatric Sleep Questionnaire consists of questions in two sub-groups to understand in night or sleep time behaviors and day time behaviors or potential problems. SPSS 16.0 package program calculated using the scores given level of significance was evaluated with chi-square test.

RESULTS: The study were a total of 50 children between the ages of 1 and 17 (7.9 ± 4.93) and 24 boys (%48), 26 girls (%52). Asthmatic children's scores in the subgroup with night and sleep time behaviors indicates a statistically significant difference compared to non-asthmatic children. According to behavior and potential problems of the day time sub-scale, the differences were not statistically significant.

CONCLUSION: Sleep is important for quality of life at all ages. Results show that, according to night behaviors and sleep quality sub-scale, asthmatic children sleep quality is affected. This low sleep quality may adversely affect the development of children. Emphasis to the asthmatic children's sleep quality may contribute to the development of these children and their quality of life.

The prevalence of Lithuanian population of familial cancer anamnesis (FCA)

Indrė Baužienė, Valerijus Morozovas

Faculty of Medicine, Vilnius University, Lithuania

Objective. Worldwide FC widespread about 10 %. We aimed to determine the frequency of FCA between the sexes and different age groups in Lithuania. Find out the most common localizations. Verify whether there is a statistically significant relationship between age and cancer localization in positive FCA group.

Materials and Methods. One time study was carried out in 2012-2014 years. We created self designed questionnaire about FC prevalence. 1200 respondents interviewed online. A statistical analysis was done and the Significance Assessed by a X-square test. The statistical Difference was Considered spreads across if the p value was below 0,05.

Results. FCA positive group accounts for 10,4 % (125): men accounted for 14.4 % (18), women - 85.6 % (107). 65.42 % (70) women were younger than 50 years old, male - 27.7 % (5). After 51 yers -34.58 % (37) women and 72.2 % (13) men. Statistically significant (p=0.002) women often have a positive FCA in 41-45 age group. Statistically significant (p=0.0001) positive FCA is the most common between 51-65 years men. 64,8% (81) of 125 respondents didn't have oncology, bet they matched positive FCA. In FCA -positive group breast cancer formed 8%, skin 5,6%, ovarian / testicular and prostate by 4,0%, blood 3,2%, large intestine 1,6%, lung cancer 0,8%, other locations 5,6 % and cancer localization wasn't known 2,4 %.

Conclusions. FC prevalence is similar in other countries. Women make up the majority of positive FCA. Increased incidence or the positive FCA observed in younger women and older men. In general, the biggest part of FCA group consists of 41-45 years group. Depending on the results, FCA history with people and their relatives should be intensively investigated in order to reduce this risk.

"Rating subjective feelings of pain, mood and general activity in patients with poly morbidity"

Zlata Mustafa Frasto, Amra Mustafa Lasic, Neda Mladen Ferizovic, Fuad Abit Husic, Lejla Mahmut Kurtalic
Public Health Center Sarajevo Canton, Bosnia and Herzegovina

INTRODUCTION: The structure of patients in the Public Health Centre Sarajevo is mostly with polymorbidity. Patients expect from health workers to improve the quality of their life and make it worth living.

OBJECTIVE: To examine whether the number of chronic diseases that the patient has influence his subjective experience of pain, mood, as well as general activity.

METHOD: The study is conducted by interviewing patients and examining medical records. Period: September-December 2014 in three family medicine teams of Public Health Center Sarajevo. Patients with two or more chronic diagnosis were tested. Examined variables: age, gender, number of diagnosis, numerical pain score during rest and descriptive assessment on quality of life: mood and general activity. Patients classified into three categories: small number (2-3), mean (4-6) and large number of diagnoses (7-10).

RESULTS: Total number of patients 120, average 61.9, SD 39.9 (55 patients up to 65 years and 65 over 65), M37 (30.8%) F83 (60.2%). 58 test subjects belong to category with small number of diseases, 53 to category with mean number of diseases, 9 to category with large number of diseases. There is no statistically significant difference in the subjective feeling of pain at rest among the three categories. $t=8306; p=0.081 > 0.05$. Subjective assessment of the quality of life—mood segment is descriptive: poor quality, neither good nor poor quality, good quality. There is no statistically significant difference in the subjective feeling of quality of life/mood, among the three categories. $t=8215; p=0.084 > 0.05$. Subjective assessment of general activities is also descriptive: poor quality, neither good nor poor quality, good quality. There is a statistically significant difference in the subjective evaluation of general activity among the three categories. $t=14\ 359; p=0.006 < 0.005$.

CONCLUSION: These findings should influence the guidelines which should be used to improve the tested segments of life for patients with polymorbidity.

A new means to promote organ donation: General Practitioners' views on discussing organ donation in the primary care setting - A qualitative study

Jennifer Nicola Maeve Rea, Richard Meakin

Primary Care and Population Health Department, University College London, London, United Kingdom

Background & AIM:

Organ shortages limit transplantation as a treatment for end-organ failure. Whilst England operates an opt-in system for donation, there is reliance on public proactivity and altruism for successful donor recruitment. At present, $<1/3$ of the UK population are registered as donors - more people need to be encouraged to donate. Previous work by this author revealed public expectation to find donation information in General Practice, suggesting an educational opportunity within primary care. Currently surgeries passively promote donation at registration or via posters/pamphlets in surgeries, there is no routine discussion with patients. Little research is available about active donation promotion in primary care or how GPs would respond to taking on this role.

METHOD:

A qualitative study design using semi-structured interviews with a purposive sample of 15 London GPs. Fram

RESULTS:

Participant GPs were conscious of the need to increase donor registration, but had limited education on donation or experience discussing it. Primary Care was acknowledged to be an ideal setting for donor recruitment and GPs were willing to increase their involvement in promotion. GPs accepted that discussion could provide meaningful donation education, but expressed concern that conversations could be time consuming and/or inappropriate for many patients. Optional discussions that were patient-led rather than doctor-led, were considered most suitable.

CONCLUSIONS:

Organ shortages in the UK are set to rise by 8% each year. With an opt-in system in place, we need to be more creative in our approach to donor recruitment. This study suggests that GPs promotional role could be expanded as part of a wider public drive to increase donation, and that discussion may have a place in promotion if offered selectively for patients who are hitherto undecided and wish to discuss further with a healthcare professional.

Pathological Internet use, cyber-bullying and mobile phone use in adolescence: a multicenter, school-based, cross-sectional study in Greece

Zoi Tsimtsiou¹, Anna Bettina Haidich², Anastasios Drontsos¹, Fotini Dantsi¹, Zafiria Sekeri³, Evangelos Drosos⁴, Nikolaos Trikilis⁵, Theodoros Dardavesis², Panagiotis Nanos⁶, Malamatenia Arvanitidou²

¹Urban Health Center of Evosmos, Thessaloniki, Greece

²Department of Hygiene, School of Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece

³Health Center of Litochoro, Litochoro, Greece

⁴Health Center of Siatista, Siatista, Greece

⁵Health Center of Chalastra, Chalastra, Greece

⁶3rd Health Authority of Macedonia, Thessaloniki, Greece

Background & Aim Although Internet is a very useful means of information retrieval, social networking and entertainment, potential hazards have been recognized in the vulnerable group of adolescents. We aimed in investigating the prevalence of Internet addiction (IA) and cyber-bullying behaviors in adolescents, their possible association and identify associated factors among socio-demographics, Internet habits and the use of mobile phones with Internet access.

Method In this cross-sectional, school-based study, 8053 students of 30 middle and 21 high schools (12 to 18 years old) in North Greece were invited to participate, based on a multistage stratified random sampling technique. Internet Addiction Test (IAT) was used along with experience of cyber-bullying (victim or/and perpetrator), socio-demographics, Internet activities and use of mobile phone with Internet access.

Results 5590 students participated (response rate 69.4%). We found that 30.1% had mild, 9.6% moderate and 0.4% severe IA, while 7.3% were cyber-bullying victims and 6.6% perpetrators during the last 12 months.

Ownership of mobile phones with Internet access was 65.2%. Younger age, hours online during a school day and surfing from mobile phones, visits in Internet cafes, use of pornographic sites, chatrooms and being a victim or perpetrator of cyber-bullying were associated with IA, while the use of athletic sites was inversely related. Hours of Internet surfing from mobile phones and IAT score were associated with both cyber-bullying profiles. Cyber-bullying victims were more likely to be female, use Facebook and chatrooms, while perpetrators to be male, use Internet longer and prefer pornographic sites. A perpetrator was 5.5 times more likely to have also been victim.

Conclusions Cyber-bullying behaviors are associated with IA and the longer hours of mobile phones use for Internet access were found associated with both conditions.

Reasons for consultation of gastric cancer in primary care in the Netherlands

Charles W Helsper¹, Kristel M Van Asselt², Roxanne Ten Bokkel², Gerline Van Den Brink¹, Niek J De Wit¹

¹Julius Centre for health and primary care, UMC Utrecht, Netherlands

²Department of Primary Care, AMC Amsterdam, Netherlands

Background and Aim

Gastric cancer is relatively rare with an incidence of 1,500 in the Netherlands. Since most patients are diagnosed in advanced stage of disease, mortality rate is high, with over 1,400 deaths each year. Moreover, gastric cancer causes a significant burden of disease. Earlier identification of gastric cancer patients is likely to reduce both mortality and disease burden.

Since symptoms and complaints are first seen in general practice, the aim of this study is to identify and quantify reasons for consultation of gastric cancer in primary care to improve early diagnosis.

Method

A case series using combined routine care data of the Julius general practitioners Network (JHN) and the GP-network-AMC (HAG-net-AMC) was performed. Files of patients diagnosed with gastric cancer between 1996 and 2014 were extracted and manually screened for recorded reasons for consultation. Screened text included coded and uncoded (free text) data.

Results

Patient files of 103 gastric cancer cases were studied. Recorded reasons for initial consultation were; abdominal pain (68.0%), anemia (39.8%), decreased appetite (36.9%), nausea (36.9%), reflux (35.9%), weight loss (33.0%), vomiting (29.1%) and constipation (23.3%). In over 70% of cases, a combination of two or more complaints was found. In 50% a combination of three or more complaints occurred.

The combination of; abdominal pain and/or decreased appetite and/or nausea and/or reflux, was found in 82.5% of patients. Abdominal pain and/or anemia occurred in 82.5%. Alarm symptoms were found in 49.5%.

Conclusion

Abdominal pain is the most frequently recorded reason for consultation in gastric cancer patients in primary care. Most GPs recorded more than one complaint. Alarm symptoms were recorded in approximately half of the patients. To determine the diagnostic value of these findings in primary care, further research is needed.

Our One-Year Experience in a Single Center in the Home-Care Nursing Services

Bahadır Yazicioglu¹, Mahcube Cubukcu²

¹Department of Family Medicine, Faculty of Medicine, Ondokuz Mayıs University, Samsun, Turkey

²Department of Family Medicine, Samsun Education and Research Hospital, Samsun, Turkey

Aim

A person who is bedridden usually needs full-time care and attention. This means that a care team will likely be working together. Bedsores are caused by prolonged pressure against the skin. They occur most on the lower part of the body. Advanced medical care in the patient's home care is becoming more common. We aimed to evaluate given the home care nursing services by Samsun Education and Research Hospital.

Methods

As of January 2011 home care nursing services are provided by the Samsun Education and Research Hospital. Patients older than 16 years are visited by going to their homes. Patients were examined, taken to the list of observation and treatment, medical records are kept meticulously. Retrospective medical record scanning, our one year experience in a single center were examined.

Results

Our clinic since it opened a total of 1939 patients were visited at home. Treatment services given the current number is 914 (612 female (%67), 302 male(%33)) patients. 884 patients died, 19 patients transferred to the other home-care service unit, 66 patients fully treated, 23 patients or relatives wanted to terminate home-care service, 33 patients were excluded from the follow-up due to change of address. We have 697(%76) bedridden, 217(%24) semi-independent patients. The number of visits made to patients were 2719. The number of dressing in last year were 1067. And the most common invasive procedure were urinary foley catheter (n=586). Blood examination was made of 408 patients. 203 patients were asked to consultation from other specialist physicians.

Conclusion

Home care services are utilized by people of all ages and backgrounds. However the program is predominantly used by elderly with multiple health conditions and limited economic means. People can receive a variety of essential medical treatments in the comfort of their own homes.

Alcohol consumption among young adults in Lithuania

Mante Barzdenyte, Monika Niedvaraite, Daiva Makareviciene, Greta Salciute, Ana Chaleckaja, Ignas Barzdenis, Virginijus Sapoka, Vytautas Kasiulevicius
Vilnius University Faculty of Medicine, Lithuania

BACKGROUND AND AIM: The data about alcohol using in young adult subjects is poor in Lithuania. The aim of our survey was to evaluate alcohol consumption models among young adults.

METHODS: A randomized survey was performed by carrying out anonymous 32 questions questionnaire covering the period from 2014 to 2015 years, collecting data on basic characteristics, tobacco and alcohol consumption models. A modified alcohol dependence scale (ADS) was used. Questionnaire was completed by 797 respondents, 794 were taken to the final analysis. Main selection criteria was age from 18 to 29 years. According to estimates of the ADS, respondents were divided into 5 groups: 0, 1-13, 14-21, 22-30, 31-47.

RESULTS: Among 794 participants, 70.0% were women, 95.2% - unmarried, mean age was 22.2±2.3 years. Of all, 50.1% respondents lived in the capital city Vilnius. The majority of subjects (41.3%) lived with their parents, 20.1% - together with the lover, and 17.1% lived in dormitory. According to the survey 92.6% had university education. Unemployed were 69.9% participants, 30.4% of young adults had steady jobs. Non-smokers were 61.2%, but a reasonable proportion of the respondents (38.8%) were constantly smoking or attached themselves to social smokers. Women had a significantly lower estimate of ADS than men ($p = 0.004$). Those who lived with their parents or the lover had lower ADS ($p = 0.034$). It was also noted that the unemployed participants were in a significantly larger alcohol dependence risk compared to the working population. There was no connection among age, city, social situation and the resulting estimate of ADS.

CONCLUSIONS: Our research showed that less alcohol consume in employed female, living with their parents or lover. **Keywords:** alcohol use, alcohol consumption, young adults

ADS Interpretation Guide

<u>ADS Raw Score</u>	<u>Interpretation</u>
0	No evidence of alcohol dependence was reported. However, this does not necessarily mean that the individual is free of dependence symptoms. Assess the validity of self-reports.
1-13 (1st quartile)	Low level of alcohol dependence. Symptoms are probably psychological, rather than physical. Moderation drinking strategies may be considered if there are no contradictions. Score of 9 or more is highly indicative of a current diagnosis (DSM-III) of alcohol abuse or dependence.
14-21 (2nd quartile)	Intermediate level of alcohol dependence. Psychological problems related to drinking are likely. Psychological dependence may still be characteristic, but look for signs of physical dependence and withdrawal symptoms.
22-30 (3rd quartile) Out-Patient/	Substantial level of alcohol dependence. Physical dependence is likely. Medical disorders, psychiatric symptoms and social problems related to alcohol abuse are probable. Abstinence treatment goal should be recommended. Clients are more likely to recognize that abstinence is the only way to improve.
31-47 (4th quartile)	Severe level of alcohol dependence. dependence is highly likely. Serious psychiatric symptoms and medical disorders related to drinking - such as liver disease - are likely. Abstinence is recommended. Check for seriousness of intentions to comply with treatment.

Study of the impact of volatile organic compounds inside of motor vehicles on human health

Paula P Rodriguez Casal¹, Ana Belen Piñón Gamallo¹, Sandra Daponte Angueira², Enrique González De La Ballina², Iris Martinez³, Santiago Perez Cachafeiro¹, André Gameiro Mendes³

¹Department of Primary Care, Integrated Management Area Pontevedra-Salnes, Galicia, Spain.

²Department of Gastroenterology, Integrated Management Area Pontevedra-Salnes, Galicia, Spain.

³Automotive Technology Centre of Galicia, Spain

INTRODUCTION: The air pollution is one of the major impacts on public health. The OSHA (Occupational Safety and Health Administration) and the IAIAQ (Promoting actions for healthy indoor air) describe the substances involved in the poor quality of indoor air, including volatile organic compounds (VOCs) and acknowledging that these substances can produce several health effects.

OBJECTIVE: The objective of this study is to evaluate the signs and symptoms which may result from exposure to VOCs and to check if they can affect driving ability.

METHODS: We made a health questionnaire, and the study volunteers were asked about a signs and symptoms that may develop during driving. It was disseminated online in Spanish and English with the collaboration of CTAG (Automotive Technology Centre of Galicia). They were activated from August to November 2014. The data were statistically analysed.

RESULTS: 269 responses were obtained. Most respondents were women (52%) between 26-35 years old (56%). the 73% did not suffer any illness on that moment and the 74% were declared not smoker. The 98.8% of respondents regularly use a car to get around and mostly (95%) occupied the driver's seat. The most frequent symptom was fatigue or tiredness in 60.66%, appearing after more than thirty minutes of driving (49.40%), and the 38.10% said it is low intensity. The rest of symptoms occur in less than 50% of respondents.

CONCLUSIONS: Currently, although there are a lot of studies on outdoor air, research in the field of indoor air quality in vehicles is still limited. The data presented shows the need to evaluate the long-term exposure to VOCs and health risks related for drivers and passengers.

Impact of Influenza Vaccination on Acute Respiratory Infections in Family Medicine

Sanda Kreitmayer Pestic, Azijada Beganlic, Olivera Batic Mujanovic
Family Medicine Department

BACKGROUND: The beginning of flu season always bring new concerns to a family medicine doctors. In this study we were interested in the relationship between influenza vaccination status and acute respiratory infections.

OBJECTIVES: To find out if there is difference among patients with chronic pulmonary diseases and chronic patients without pulmonary diseases, both vaccinated against influenza, in getting acute respiratory disease.

METHODS: This retrospective study included 138 patient records (experimental group), age 65 or more, with asthma and/or COPD who were vaccinated in 2013/2014. The controlled group was matched by age and gender, had at least one chronic disease, and were not influenza vaccinated. After reviewing 276 medical records, statistical analyses were performed. We also reviewed 70 medical records of unvaccinated patients with no chronic diseases, for additional comparison.

RESULTS: The influenza vaccinated patients with chronic respiratory diseases showed a minimal statistically insignificant difference versus the control group of influenza unvaccinated patients in catching acute respiratory infection/disease and in number of visits to their family doctor. The number of acute respiratory infections and visits to doctor was smaller in the vaccinated group compared to the unvaccinated chronic patient group. The differences were inconclusive due to small sample in the control group of patients.

CONCLUSIONS: The study showed statistically insignificant difference among both groups for acute respiratory disease and the number of visits to family doctor in the flu season.

²Istanbul University, Cerrahpasa Medical Faculty, Department of Family Medicine M.D, Resident

³Istanbul University, Cerrahpasa Medical Faculty, Department of Public Health M.D, Assistant Professor

⁴Istanbul University, Cerrahpasa Medical Faculty, Department of Family Medicine M.D, Professor

AIM: The registered patients in family medicine department of Cerrahpasa Medical Faculty between 2004-2014 were analyzed retrospectively and the frequency of complaints and diagnoses were evaluated to create a patient profile. **MATERIAL-METHOD:** A total of 748 patients admitted to the family medicine outpatient clinic were analyzed retrospectively by student-t test and χ^2 . They were examined by either of three doctors; one resident, one senior doctor and one professor. **RESULTS:** There were 324 male patients and 424 female patients. Their mean age was 53.13 ± 15.62 for males and 55.14 ± 15.66 for females ($p > 0.05$). The referral rate was 14.4%, prescription rate was 32.9% and diagnostic tests were needed in 77.3% of patients. In the registered male patients, complaints like chest pain ($p = 0.046$) and overweight ($p = 0.02$) were more frequent than female patients. In the female patients; musculoskeletal pain ($p = 0.001$), dizziness ($p < 0.05$), dyspepsia ($p < 0.05$) and oedema ($p = 0.014$) were more commonly encountered. In male patients, hypertension ($p < 0.01$), diabetes ($p < 0.05$), hyperlipidemia ($p < 0.001$) and cardiac diseases ($p < 0.05$) were observed more than female patients whereas anemia ($p < 0.01$), thyroid diseases ($p < 0.05$), gastrointestinal system diseases ($p = 0.043$) and musculoskeletal system diseases ($p < 0.01$) were more frequent in female patients. There was no difference between referral, prescription and diagnostic tests in terms of gender. **DISCUSSION:** Hypertension, which can be diagnosed easily in primary care was the most frequent disease in this study (32.4%). This finding is in concordance with the result of the Patent 2

study conducted by Turkish Hypertension and Renal Diseases Association in 2012 in Turkey (%31.8). Hypertension was the most common disease in males (32.5%) and second most common disease in females (28.5%). Its early diagnosis is important to prevent stroke, myocardial infarction and ischemic heart disease. Malignant diseases were least encountered in the patient group. This may result from their direct admittance to related specializations. Increasing consciousness and knowledge level in screening and referral of malignant diseases in primary care is recommended.

⁴Vicomtech-IK4. San Sebastián. Spain

⁵Neurovascular Research lab. Vall d'Hebron Research Institute. Universitat Autònoma de Barcelona. Spain

⁶Hospital de Barcelona. Spain

⁷Hospital Municipal de Badalona. Spain

Background & AIM: Silent brain infarcts predict an increased risk of stroke, especially in hypertensive patients. The retinography is a useful technique that allows non-invasive visualization of the vascular tree. This study evaluates the utility of retinography with nonmydriatic fundus camera as a risk factor of silent brain infarcts in hypertensive population aged 50 to 70 years old without previous clinical stroke.

METHOD: Cross-sectional, observational, analytical study. 976 hypertensive adults aged 50 to 70 years old who underwent a Magnetic Resonance Imaging Study (MRIS) to detect silent brain infarcts in context of ISSYS project (FIS 10/00705). Case is the patient who had silent brain infarcts diagnosed by MRIS. An interview to obtain socio-demographic data, drug treatment, cardiovascular risk factors and comorbidities was performed. EKG, basic blood test and a retinography analysis by nonmydriatic fundus camera was performed in all individuals and retinal vascular abnormalities were determined. Measurement of arterio/venous ratio using semi-automatic measurement and retinal changes by Keit-Wagener classification was performed by an experienced ophthalmologist.

RESULTS: 775 participants, MRIS and retinography analysis was obtained. Silent brain infarcts prevalence was 81 (10.5%). In a multivariate logistic regression analysis a pathological arterio/venous ratio (<0.666) increases the OR: 3.85 (95% CI 2.2 to 6.8) of having silent brain infarcts and a Framingham-calibrated Registre Gironí del Cor (REGICOR risk) > 10 increases OR: 3.74 (95% 1.7 to 8.3) of having silent brain infarcts. Keit- Wagener classification grades 1-4 does not increase significantly the risk.

CONCLUSION: Pathological arterio/venous ratio and REGICOR risk charts are independent risk factors for silent brain infarcts. Arterio/venous ratio could be used as a risk factor of silent brain infarcts in order to stratify specific population into risk groups and take actions to prevent future strokes.

The Usage Level of Family Planning Method Among The Married Women Aged Between 15-49 in a Primary Health Care Region of Samsun

Mahcube Cubukcu¹, Bahadir Yazicioglu²

¹Department of Family Medicine, Samsun Education and Research Hospital, Samsun, Turkey

²Department of Family Medicine, Faculty of Medicine, Ondokuz Mayis University, Samsun, Turkey

Aim: Family planning is the planning of when to have children, and the use of birth control and other techniques to implement such plans. Other causes commonly used include sexuality education, prevention and management of sexually transmitted infections, pre-conception counseling and management, and infertility management. This study has been carried out to determine the usage level of family planning method among the married women aged between 15-49 in Vezirkopru district in Samsun.

Methods: In the district Vezirkopru of Samsun city, married women in the 15-49 age range, family physician's records about family planning methods examined retrospectively. Used or not used contraceptive methods by women were divided into groups.

Results: 937 women were included in the study age range 15-49. It was determined that 61% of the women (n=572) use a method of birth control and 39% (n=365) do not use any method. The prefer of contraceptive methods were; 146 women use traditional protection methods, 217 women had tubal ligation, 114 women's partner use condoms, 60 women have intrauterine device (IUD), 30 women take oral contraceptives, 5 women to make estrogen injections. The causes of why protection methods not used were; 44 women were breast-feeding, 110 women did not want to use any contraceptive method, 48 women wanted to get pregnant, 92 women were pregnant, 8 women were infertile, 63 women were postmenopausal.

Conclusions: Women do not know modern methods of contraception. Contraceptive methods are not used effectively. Based on these results it is recommended that patients can be informed about contraception and men be included in planned undertakings for more effective family planning services.

Feasibility and results of abdominal ultrasound in primary care

María Cordobés Millán¹, Sílvia Crespo Blas¹, Ana Marqueño Ellacuría¹, Marc Tarín Martí¹, Angela Inés Vieira Rodríguez¹, Manel García Lareo², Yolanda Linares Sicilia¹, Diego Sebastián Yanel², José Miguel Baena Díez²

¹Resident de Medicina Familiar i Comunitària, CAP La Marina, Barcelona, Espanya

²Metge de Família, CAP La Marina, Barcelona, Espanya

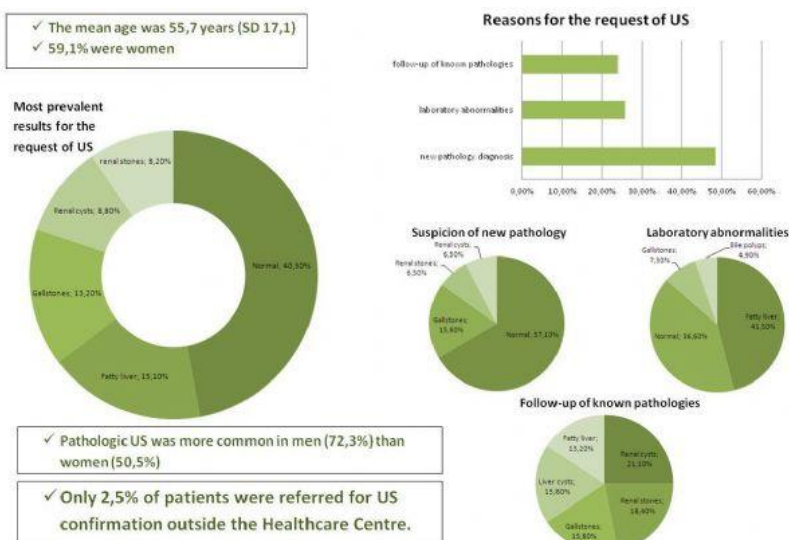

Background and aim. Abdominal ultrasound is a diagnostic tool used frequently in general practice. The aim was to study the results and feasibility of abdominal ultrasound in Primary Care.

Method. Cross-sectional study was performed in a urban health centre. 159 patients were included over a period of 14 months. Ultrasounds were performed by a general practitioner after an specific training. The protocol included the following variables: age, gender, reason for request (laboratory abnormalities, known pathologies' follow up, diagnosis of new pathology, and other reasons), and ultrasounds diagnosis. Proportions were compared using Chi-square test and the mean with t-test.

Results. The mean age was 55.7 years (SD 17.1), 59.1% were women. The most frequent reasons for the request were: diagnosis of new pathology (48.4%) laboratory abnormalities (25.8%) and known pathologies follow up (23.9%). The most prevalent results were: normal ultrasound (40.3%), fatty liver (15.1%), gallstones (13.2%), renal cysts (8.8%) and renal stones (8.2%). When new pathology was suspected the most common diagnoses were: normal ultrasound (57.1%), gallstones (15.6%), renal stones (6.5%), and renal cysts (6.5%). In the case of laboratory abnormalities the results were: fatty liver (41.5%), normal ultrasound (36.6%), gallstones (7.3%) and bile polyps (4.9%). When known pathologies were controlled: renal cysts (21.1%), renal stones (18.4%), gallstones (15.8%), liver cysts (15.8%), and fatty liver (13.2%). Pathologic ultrasound was more common in men than women (72.3% versus 50.5%, p = 0.006) and when comparing laboratory abnormality and diagnosis of new pathology (63.4% versus 42.9%, p = 0.029). Only 2.5% of patients were referred for ultrasound confirmation outside the health centre.

Conclusions. Abdominal ultrasound in Primary Care is feasible, allows the follow up of known pathologies, and permits the diagnosis of new diseases.

Tinnitus prevalence and effect on sleep quality

Erkan Melih Sahin, Mustafa Turan Ozdemir, Yusuf Haydar Ertekin, Aysegul Uludag
Department of Family Medicine, Canakkale Onsekiz Mart University, Canakkale, Turkey

Background & Aim

Tinnitus is a global problem effecting 278 million people and up to 15% of the population. Clinical conditions like depression and suicide are seen in about 20% of the tinnitus patients that also have serious decline in health quality mostly attributed to decline in sleep quality. The aim of this study is to determine the prevalence of tinnitus in adults living in Çanakkale, Turkey and effect of tinnitus on sleep quality.

Method

Study sample were selected from Çanakkale adult population 18 years and older who attend to primary care centers for any reason using a cluster sampling. Demographic characteristics, tinnitus symptom and medical history were questioned and Tinnitus Reaction Questionnaire (TRQ) and Tinnitus Handicap Questionnaire (THQ) were applied to detect severity of tinnitus. Subjective sleep quality was evaluated using Pittsburg Subjective Sleep Quality Index (PSQI).

Results

Tinnitus were found 36 (7.2%) of the 500 participants. Mean TRQ score was 18.8 ± 8.9 , and mean THQ score was 20.9 ± 10.3 in tinnitus patients. Mean PSQI score of the participants was 4.4 ± 2.6 and there were 171 (34.2%) people with a 5 or higher PSQI score which interpreted as worse sleep quality. PSQI score of the tinnitus patients (5.8 ± 3.1) were significantly higher than others (4.3 ± 2.5) ($U=5813$; $p=0.002$). Rate of worse sleep quality among tinnitus patients (12.3) were significantly higher than the non-tinnitus patients (4.6%) ($\chi^2=10.040$; $p=0.002$). The PSQI score did not correlate with TRQ or THQ scores.

Conclusions

The prevalence of tinnitus found lower in our region according to our results. Participants might not declare lesser symptoms that did not effect their quality of life. Our results confirmed the relation of sleep quality and tinnitus. Sleep quality should be a part of the follow-up of tinnitus patients for a proper health care.

Keywords: Tinnitus, prevalence, sleep quality

"The Prevalence of Internet Addiction and Related Factors among Healthcare Workers"

Dilek Kusaslan Avci, Huseyin Avni Sahin

Department of Family Medicine, Medical Faculty of Yuzuncu Yil University, Van, TURKEY

AIM:

The aim of the study was to determine the prevalence of Internet addiction and related factors among Healthcare Workers.

METHODS:

A total of 180 health workers were included in the study in a university hospital in Van. Research data were collected with a questionnaire consisting of two parts. In the first section there were 24 questions including socio demographic information, smoking and methods of coping with stress. The second section includes Turkish version of Internet Addiction Scale.

RESULT:

The study population consisted of 81 female (44.5 %) and 99 male (55.5 %). Participants were physicians (31.1%), nurses (47.8 %) and other employees (21.1 %). The results showed that, 57.1 % of the physicians, 53.4 % of the nurses and 31.5 % of other employees were at high-risk group. Furthermore 10 % of the females and 17 % of the males were at high risk group, 37.5 % of the females and 42 % of the males were at low risk group. The rate of chat with friends as a method of coping with stress were 61.1% in the high risk group, 40.2% in the low risk group and 22.4% in the risk-free group. The results showed that, 60.4 % of smokers and 44.3 % of non-smokers were at risk-free group.

CONCLUSIONS:

Even though Internet addiction rates were lower among participants who prefer going for a walk, reading a book, going shopping, doing housework or playing musical instruments as a method for coping with stress, were high among others. New strategies are essential in terms of gaining healthy attitudes among health workers.

Face and content validation of a symptom diary for patients with suspected urinary tract infection (UTI) in primary care

Anne Holm, Gloria Cordoba, John Brodersen

The Research Unit for General Practice and Section of General Practice, Department of Public Health, University of Copenhagen, Copenhagen, Denmark

BACKGROUND & AIM

Studies investigating UTI often include patient-reported outcomes measures (PROMs), but none of the existing PROMS were validated for complicated UTI and they had not considered that each item in a questionnaire can contribute differently to the measurement of the construct. The aim of this study was to develop and validate a condition-specific PROM on symptoms in adults with UTI in primary care divided into three domains: patient-reported symptom severity, bothersomeness and impact on daily activities.

METHOD

The study group identified symptoms and activities relating to UTI from the literature. Response categories were added to generate a first draft version of the diary. Content validity (relevance and coverage) was ensured by conducting single interviews and focus groups with women and men who had previous had at least one UTI. Participants were recruited from the university practice clinic, urological departments (men), a seniors’ activity center and the researchers’ network.

RESULTS

The first draft version of the PROM encompassed 21 items (eight symptoms and five daily activities) and response categories from 0 (none) to 3 (a lot). Two focus groups and nine single interviews resulted in 23 additional items. One item was discarded as not relevant. In the final interviews, no new items appeared, and we concluded, data saturation was reached (see table).

CONCLUSIONS

All three domains were confirmed to be relevant for patients with an UTI. The domains of symptom severity encompassed 18 items, the domain bothersomeness 18 items and the impact on daily activities domain seven items. The items included in these three domains will be psychometrically validated using the partial credit Rasch model for polytomous items.

Keywords: Urinary Tract Infections [Mesh], Symptom-diary, Patient-reported outcomes

Impact Of Low-Density Lipoprotein Cholesterol On Complete Blood Cell Parameters In Non Diabetic Women

Esra Durmuş, Cenk Aypak, Münevver Tulunay, Hilal Yüksel, Hülya Yıkılkan, Derya İren Akbıyık, Süleyman Görpelioğlu

Department of Family Medicine Dışkapı Yıldırım Beyazıt Research and Training Hospital, Ankara, Turkey

Background & Aim

Epidemiological and clinical studies have clearly established the link between low-density lipoprotein cholesterol (LDL-C) and atherosclerosis-related cardiovascular consequences. Whereas diabetes mellitus and obesity have been associated with leukocytosis, the relationship between serum LDL-C and other hematopoietic lineages is poorly defined. Therefore we aimed to examine the relationship between serum LDL-C and complete blood count (CBC) indices in non-diabetic Turkish women.

Methods

The study was carried out among adult women who attended routine health examination at Family Medicine outpatient clinics of Dışkapı Yıldırım Beyazıt Research and Training Hospital. Sixty, nonsmoker, non-diabetic women without hematological diseases and who were not receiving any medications known to affect blood, glucose and lipid metabolism were recruited to study. Subjects were divided into groups according to their serum LDL-C levels (group 1: LDL-C < 160 mg/dl and group 2: \geq 160 mg/dl).

Results

The mean age of the study population was years. There were no statistical differences in age, body mass index, waist circumferences, fasting blood glucose, creatinine, total cholesterol, triglycerides, high density lipoprotein-cholesterol alanine aminotransferase and white blood cell counts between two groups. LDL-C, hemoglobin, hematocrit and platelets were found to be higher in group 2. There were inverse associations among Hct, Hgb and LDL-C in group 2. ($\rho = -0.441$; $p = 0.017$ and $\rho = -0.454$; $p = 0.013$ respectively).

Conclusions

As LDL-C levels impact cardiovascular disease risk, there is a need for understanding of the underlying interactions between LDL-C and CBC components.

Illness Perception Characteristics in Chronic Obstructive Pulmonary Disease Patients And Factors Affecting Illness Perception

Gulden Bilgin¹, Elif Cirit², Ismail Arslan², Didem Sunay³, Oguz Tekin²

¹Department of Chest Diseases, Ankara Training and Research Hospital, Ankara, Turkey

²Department of Family Medicine, Ankara Training and Research Hospital, Ankara, Turkey

³Department of Family Medicine, Kecioren Training and Research Hospital, Ankara, Turkey

Chronic obstructive pulmonary disease(COPD) is a systematic disease which is characterized with non reversible progressive airflow obstruction. In the present study, a revised form of Illness Perception Questionnaire (IPQ) was used, and the relationship between the severity of the disease and various factors of IPQ were investigated in COPD patients.

The study was carried out at the Ankara Training and Research Hospital between January and June 2014. One hundred forty-seven patients (109 males, 38 females) were included in the study. Patient selection was based on the following criteria: regular COPD treatment for a minimum of six months, age >18 years, voluntary participation, and ability to be in contact. Informed consent forms were obtained from all patients. Ethics approval was obtained from the institutional ethics committee.

The study revealed that COPD stage, age, and loss of strength had an effect on the perception of the disease as chronic. In addition, the research demonstrated a positive correlation between age and scores. We found that COPD stage, age, and pain had an effect on the perception of disease outcomes as severe. The research revealed a positive correlation between age, disease stage, and scores. The mean scores were higher in patients with pain. In conclusion, disease perception is associated with patients' experiences throughout the disease, course of disease, and coping mechanisms. The number of studies on the disease perception is limited in Turkey. We believe that our study is instructive in this field, and the investigation of different variables, which could affect disease perception, in larger study groups might contribute to the analysis of disease perception.

Awareness of hypoglycemia symptoms in patients with type 2 diabetes mellitus

Michail Vakas¹, Kyriakoula Tsolaki², Alkmini Theochari³, Foteini Fragkoudi⁴, Sofia Kourtparasidou⁵, Nikolaos Papanas¹, Dimitrios Papazoglou¹

¹University General Hospital of Alexandroupolis, Evros, Greece

²Health Center of Sapes, Rodopi, Greece

³Health Center of Orestiada, Evros, Greece

⁴Health Center of Prosotsani, Drama, Greece

⁵Health Center of Amyntaio, Florina, Greece

INTRODUCTION: The aim of this study was to evaluate the knowledge of patients with type 2 diabetes mellitus (T2DM) on hypoglycemia in certain areas of northern Greece.

Patients and METHODS: This study included 195 diabetic patients (117 females, 78 males), who visited us in primary health care units. Of these, 77% were of rural or suburban origin. We used a questionnaire of closed-type questions.

RESULTS: Overall, 195 patients, 94 (48.2%) had experienced one or more episodes of hypoglycemia from the onset of the disease, and 44 (46.8%) of those were under sulfonylurea treatment. The mean T2DM duration was 13 years. To the question "Has your physician informed you about hypoglycemia symptoms and how to cope with it?" 99 patients (50.8%) responded negatively, and to the question "Do you know what the symptoms of hypoglycemia are?" 80 patients (41%) answered that they were not aware of them.

CONCLUSIONS: A substantial proportion of our T2DM neither recognized hypoglycemia symptoms nor had been informed about them by their physician. Regrettably, almost half of primary care physicians in our region had neglected the very important task of educating patients on the symptoms and dangers of hypoglycemia.

Social and health problems and Family Health Strategy: a diagnosis of Vila DNOCS, a village of Brasília, capital of Brazil

Ananda Dos Santos Conde, Thiago Cavalcante Magalhães, Ubirajara José Picanço De Miranda Junior
Escola Superior de Ciência da Saúde(ESCS), Brasília, Brasil

Background & AIM: The DNOCS Village, in Federal District of Brazil, is a place with a history of migration culminating in current social and health problems character. Actually, 488 families live there and the professionals of Family Health are the only social facilities on village. These professionals are in problem, because are surrounded by violence, unemployment and lack of effective public policies, interfering in the planning of health activities in the village. **METHOD:** To understand the challenges of the local health professionals, we elaborated a social and health diagnosis from a risk scale based in the form A of the Information System for Primary Care (Ministry of Health- Brazil). This scale is based on risk sentinels and was adapted of Coelho e Savassi scales (COELHO; SAVASSI, 2011). **RESULTS:** In total were analysed 545 forms. It has been demonstrated that unemployment (in 190 families - 34.86 % of forms), Hypertension (131 families - 24.03 % of forms) and the illiteracy (105 families - 19.26% of forms), are the main problems recorded in the records. However, problems such as violence - that was experienced during the observation of the health professionals in their activities in the village - not were registered (only 1 form from 545 forms), corroborating for a misperception of the local situation. **CONCLUSION:** The results demonstrate the close relationship between health and social structure and as well the failures to registration of the health problems on the forms analysed. The systematic use of the forms can be a instrument to reorganizing the demand, but also can help not only in prioritizing home visits, as well can assist the communication between primary care and resource health managers and other social policies.

"{" Vitamin D levels and related factors in patients with Hashimoto's Thyroiditis "}"

Melike Kurtoğlu Yakıcı¹, Irem Cantürk¹, Zuhale Aydan Sağlam¹, Celal Ulaşoğlu²

¹Istanbul Medeniyet University Göztepe Training and Research Hospital; Department of Family Medicine

²Istanbul Medeniyet University Göztepe Training and Research Hospital; Department of Gastroenterology

" AIM: To assess the 25-OH vitamin D(VitD) levels in patients with Hashimoto's thyroiditis(HT) and assess the relationship with some related factors.

MATERIALS-METHODS: Serum VitD levels were assessed in 109 HT patients (M/F:11/98; age:53.8±14.7years) and 104 healthy euthyroid controls (M/F:24/80;age:52.4±14.7years). VitD status was defined as normal (≥30ng/ml), insufficient (20-29ng/ml), deficient (10-19ng/ml) and very deficient (<10ng/ml).The groups were analysed accordingly with related factors (age, gender, sufficiency of exposure to sunlight, TSH, B12 and being under medication of L-thyroxine).

RESULTS: Mean VitD level was lower in HT patients than controls(p=0.006) which was 17.3±9.5ng/ml and 21.1±6.8ng/ml for males, and 18.1±13.5ng/ml and 19.3±8.5ng/ml for females in HT and controls(p=0.84 vs p=0.25;resp).Defining VitD levels as normal, insufficient, deficient and very deficient revealed an increase in ratio of HT/control cases as 0.77, 0.84, 0.88 and 2.9 respectively(p=0.04)*.The geometric mean of Vit D level was 1.25±0.18 and 1.17±0.24 for HT and controls, respectively(p=0.006).Vit D levels of young, middle and old age groups in HT and control group were similar(p=0.77;p=0.10 resp.).Insufficient solar ultraviolet B exposure indicated significantly lower vit D levels in HT patients as expected(p=0.01). Age, gender, B12 level, TSH levels and receiving L-thyroxine had no significant influence on VitD levels.In median test, there was no difference between age groups of HT cases, while in young healthy group predominantly females had lower VitD levels(p=0.046).VitD was highly correlated with HT and the HT/control case ratio increased as the vitamin level decreased.Very deficient VitD group revealed a three-fold increase in the risk of HT. VitD levels were significantly influenced by exposure to solar UV-B in all groups.

Discussion and CONCLUSION: Low VitD levels seem to be related with Hashimoto's thyroiditis and appropriate sunlight exposure may be helpful for these patients. Large scaled randomised studies are necessary to clarify the role and possible benefits of VitD replacement in managing HT. "

Observational study of home visits for the Prehospital Emergency Care

Ana Isabel Beiro Piñeiro, Paula Pilar Rodriguez Casal, Elisa Romero Garcia, Carmen Arca Pichel, Santiago Perez Cachafeiro

Department of Primary Care, Integrated Management Area Pontevedra-Salnes, Galicia, Spain.

INTRODUCTION:

Prehospital Emergency Care (PEC) performs attention to patients out-of-hours health centres services and not accessible places by hospital services. There are multiple studies that investigate the demand for the PEC, but there are few publications which have described the special features of the urgent home care.

OBJECTIVE:

Our aim is to describe the features and types of urgent home care in the PEC.

METHODS:

A cross sectional study was designed. Socio-demographic and clinical data of patients seeking home health care for 6 months (September 2014 to February 2015) were collected. Different parameters of affiliation, dating, diagnosis and treatment were included. The data were treated statistically.

RESULTS:

A total of 162 visits were observed. Most (65.4%) patients were older than 76 years and they were women (64.2%). More than half of health care (56.2%) were in the afternoon, in an urban area (63%). the 48.1% of home visits were made by taxi whose were being alerted by the call centre (061) in 71% of them. About half (51.2%) remained at their home. The diseases most frequently requested were respiratory infection (24.7%), neurological disorders (21%) and certification of death (17.3%).

CONCLUSIONS:

The home visits were 2% of the total number of patients seen in these 6 months. Two parts of three were persons over 75 years. People's life expectancy is increasing, so it would be reasonable to expect in the near future more

home visits in elderly people or people confined to bed or with serious mobility limitations. This study is important in order to being prepared to what we could more frequently find in a situation with just us and our doctor's bag.

Study of the impact assessment of exergames in BMI percentile range of children aged 7-14

Ana Belen Piñon Gamallo¹, Paula Pilar Rodriguez Casal¹, Santiago Perez Cachafeiro¹, Margarita Boullosa Estevez¹

¹Department of Primary Care, Integrated Management Area Pontevedra-Salnes, Galicia, Spain.

²Department of Pediatrics, Integrated Management Area Pontevedra-Salnes, Galicia, Spain.

INTRODUCTION:

Overweight and obesity on children is one of most serious problems of the public health in the century XXI. While practicing physical activity (PA) is essential for growth and health in childhood, over the last decades children sedentary has been increased. The appearance of videogames on the market which involve PA, called exergames, it creates the opportunity for children to employ more energy than is used on classic games, representing a new alternative for maintaining an active lifestyle.

OBJECTIVE:

To evaluate the association between BMI percentile range and the use of active videogames on children of 7-14 years.

METHODS:

A cross-sectional descriptive study was performed. The data was collected for 12 weeks, under parental consent. It was made with volunteer children who attended at the consultation of paediatrics in Marín (Pontevedra).

RESULTS

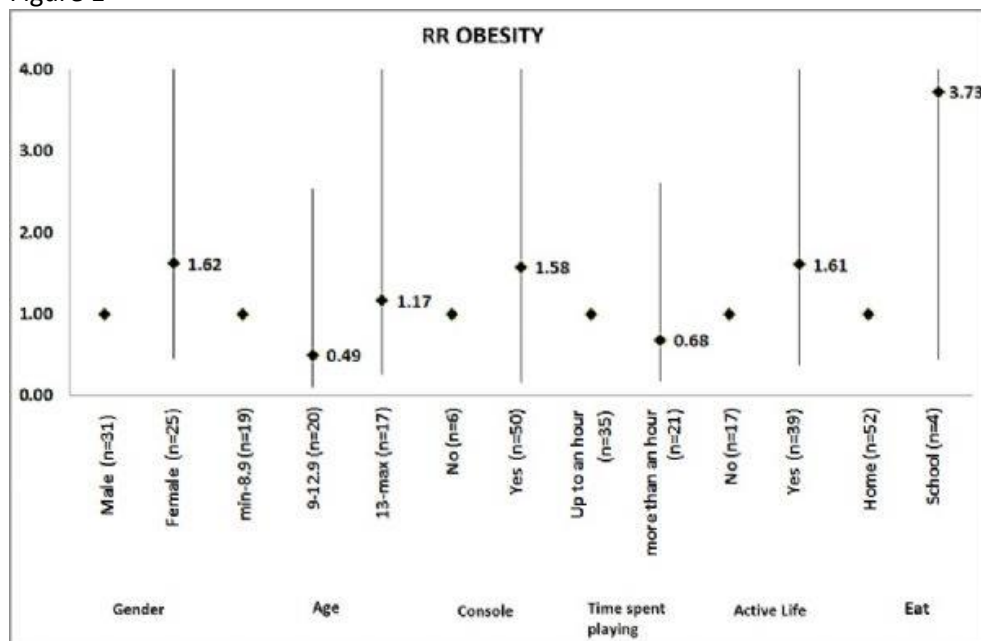

The survey of 56 children, 31 males (55.36%) and 25 women (44.64%) with a mean age of 11.10 years was performed. Approximately a quarter (23.21%) were above the 95th percentile of weight. The 89.29% have a home console, the most frequent is the Wii (51.79%) and the PlayStation (42.86%). The 69.64% of them have exergames. Only 6% of those with console are overweight, compared to 16.67% of those without. The time spent on active consoles is 1.86 hours a week, while employing 4,56hours in other aerobic activities.

CONCLUSIONS

The exergames represent a new alternative of PA which if practiced regularly it could reach the daily minimum recommended PA. However, we have to keep in mind that not all active videogames require the same intensity of PA. So we think it is necessary more research in this field.

Drug Usage Habits of Admitted Patients to Department of Family Medicine Outpatient Clinic

Bahadır Yazıcıoğlu, Fusun Yaris, Mustafa Fevzi Dikici

Department of Family Medicine, Faculty of Medicine, Ondokuz Mayıs University, Samsun, Turkey

Introduction&Aim

Rational drug usage has been defined as "in accordance with the patients' clinical symptoms and individual characteristics in sufficient duration and dose of medication the lowest price and easily providing".

There are some criterias of it just like true indication, correct drug, appropriate dose and duration, patient informed adequately, observing the usage medication process and evaluation. Left-over drug is one of them. It is aimed to investigate the drug usage habits of admitted patients at our clinic and measure the prevalence of "left-over drugs" at home and the affecting factors.

Methods

Research was performed by 51 voluntary patients who admitted to Ondokuzmayis University Faculty of Medicine Department of Family Medicine Outpatient Clinic between 01-25 July 2014 that selected randomly. Drug usage questionnaire prepared by reviewing literature and applied to patients participating in the research. Results were analyzed with descriptive statistical tests by SPSS 16.0 packet programme.

Results

In our study, 19 men (37.3%) and 32 women (62.7%) participated. The average age of participants were 39.8 year (± 12.14). The percentage of those keep left-over drug at home was found 70.6% (n = 36). The 45.1% of patients (n = 23) apply a physician firstly, 41.2% (n = 21) begin treatment with drugs in the home and 13.7% (n = 7) await the healing of the disease without doing anything when get sick. The 78.4% of patients (n = 40) has left full or part of the prescribed medications before end of the treatment.

Conclusion

Most of participants have left-over drug at home. Approximately, half of our patients are trying to treat themselves when they are sick. It is concluded that patients use drugs irrationally, Further studies on drug usage habits and rational drug usage in society can be beneficial for the promotion of rational drug usage.

Intervention for smokers through new communication technologies: What perceptions do patients and healthcare professionals have? A qualitative study

Jose Manuel Trujillo Gómez¹, Laura Díaz Gete², Carlos Martín Cantera³, Raquel Burón Leandro⁴, Elisa Puigdomenech¹, Beatriz García Rueda⁵

¹Institut Universitari d'Investigació en Atenció Primària Jordi Gol (IDIAP Jordi Gol), Barcelona, Spain

²Primary Healthcare Centre, La Sagrera, ICS, Barcelona, Spain;

³Primary Healthcare Centre, Passeig de Sant Joan, ICS, Barcelona, Spain

⁴Primary Healthcare Centre, Turo, ICS, Barcelona, Spain

⁵Primary Healthcare Centre, Navarclés, ICS, Barcelona, Spain

Background and AIMS: The use of information and communication technologies (ICTs) in the health service is increasing. In spite of limitations such as lack of time and experience, the deployment of ICTs in the healthcare system has advantages and utility for patients and health professionals. ICTs may be helpful as either interventions on their own or as complementary tools to help patients stop smoking. The aims were to gather opinions from medical professionals and smokers about an email-based application designed by our research group (TABATIC) to help smoking cessation and identify the advantages and disadvantages associated with interventions based on the utilization of ICTs for this purpose.

METHODS: A qualitative, descriptive–interpretative study with a phenomenological perspective was performed to identify and interpret the discourses of the participating smokers and primary healthcare professionals. A theoretical sample was designed for the selection of participants. Data were obtained through two techniques: semi-structured individual interviews and discussion groups, which were recorded and later systematically and literally transcribed together with the interviewer's notes. Data were analyzed with the ATLAS TI 6.0.

RESULTS: Seven individual interviews and four focal groups were conducted. The advantages of the application based on the email intervention designed by our research group (TABATIC) were said to be the saving of time in consultations and ease of access for patients who found work timetables and following a program for smoking cessation incompatible. The disadvantages were thought to be a lack of personal contact with the healthcare professional, and the possibility of cheating/ self-deception and a greater probability of relapse on the part of the smokers.

CONCLUSIONS: Patients and healthcare professionals viewed the email-based application to help patients stop smoking as a complementary aid to face-to-face consultations. Nevertheless, ICTs could not substitute personal contact in the smoking cessation program.

¹⁰Primary Healthcare Centre, Calella, ICS, Barcelona, Spain

Background and AIMS: Obesity and physical inactivity are associated with chronic diseases and mortality. Sedentary behavior is increasingly common in primary care consultations. The aim of the study is to determine the magnitude of this behavior in overweight and obese patients, their relationship with chronic diseases, activities that are performed sitting and their willingness to diminish them.

METHODS: Descriptive observational study. 464 mild obese and overweight patients (41.6% male, 51.9±10.10 years, 54% of them had a job) from 25 Primary Health Centres (PHC) were selected. The study variables were: age, gender, chronic diseases, prolonged sitting time and sitting activities in working and nonworking days (Marshall Sitting Questionnaire, MSQ) and willingness to diminish them (stages of change).

RESULTS: The overall median was 6.2 hours/day of sitting time on working days and 6.0 hours of non working days. 49.6% were sedentary (≥6 hours a day sitting). The most frequent pathologies were: hypertension (44.4%) and dyslipidemia (41.2%). The main sitting activities were: a) working day: work or academic activities 34.4% sitting (2.1 hours) and watching TV 33.3% (2 hours); b) non-working day: the most frequent activity was watching TV 49.9% (3 hours). Regarding to willingness to reduce the sitting time, 47.6% had not considered to change this behavior (precontemplation phase).

CONCLUSION: The present findings show that about half of patients with overweight and obesity are sedentary and therefore a high-risk group to target for reducing prolonged sitting time. Knowing that activities performed in sitting position and willingness to change will help us design interventions in primary care to reduce this behavior. The study is partially funded by Instituto de Salud Carlos III (PI11/01082).

Is It Possible No Psychotropic In Jail?

Suat Sincan¹, Zekeriya Aktürk², Abdulkadir Kaya², Kenan Taştan²

¹Atatürk University Student Health Center

²Ataturk University Medical Faculty Department of Family Medicine

Introduction

It's usually difficult to work in a jail, as a family physician. Usually, drugs have been given for the relaxation of prisoners but unfortunately, the prisoners who have used these drugs are bleeding wounds of prison and are responsible for the majority of criminal cases in these institutions.

Method

The number of prisoners using psychotropic drugs were determined in an E type closed prison in Erzurum. Solutions and alternative treatment plans were created in a meeting with specialist physicians on Psychiatry, Neurology and Physical Therapy. Drugs that have been used by convicts who were referred to hospital, have been replaced with non-psychotropic drugs suitable for the alternative treatment. Unless medical necessity, the green prescription and psychotropic drugs were not suggested for the prisoners.

Results

164 of 550 prisoners (29.8%) were using green prescription medication, and 46 of 550 prisoners (8.3%) were using psychotropic drugs. Because of the taking these drugs high and uncontrolled doses, it was seen that 728 prisoners harming to himself and someone else in the form of cut were happening per year. Six months later, the number of prisoners using green prescription drug decreased to 0 (0%) and the number of prisoners using gabapentin, etc. 11 (2%). After the first year, a total of 8/ year, at the end of the second year 4 / year were encountered with a cut in the form of self-mutilation incident, depending on the dose of drug intake inappropriately.

Discussion

Prisons are places that are difficult for physician because of incompatible prisoners and the drugs they use. These drugs are given to prisoners to pacify them, may cause greater legal and illegal problems. Therefore, if there in no indication, such drugs avoid prescribed, can significantly reduce criminal incidents that may arise in prison.

Results Of Fecal Occult Blood Screening Among Prisoners

Suat Sincan¹, Zekeriya Aktürk², Abdulkadir Kaya², Kenan Taştan²

¹Atatürk University Student Health Center

²Ataturk University Medical Faculty Department of Family Medicine

Introduction

Given to the prison health services, the Ministry of Justice, the Ministry of Internal Affairs and the Ministry of Health's signed together the 'Triple Protocol' which was implemented after the Health Transformation project in Turkey. Thus, according to the regulations and provisions of all tasks assigned to the tripartite protocol, family physicians should be employed in prisons. One of these tasks is fecal occult blood screening in between 50-70 years old people.

Methods

In this study, we examined convicts and arrested people who stayed in Campus of Erzurum Prison and all males from 50 - 70 years were enrolled in this study. The study protocol has explained, those who accepted to participate in the study, filled the informed consent form. A questionnaire for demographic data were obtained. Results positive, has been consulted by the relevant departments to treatment and follow-up program in Erzurum Regional Training and Research Hospital and colonoscopy was applied.

Results

Out of 1452 prisoners 189 (13%) were identified between the ages of 50-70. 161 prisoners (11%) who participated in the study from 189, fecal occult blood test were applied. Out of 24 positive (1,6%), 22 patients (1,5%) underwent colonoscopy in Erzurum Regional Training and Research Hospital. 2 convict did not want to make colonoscopy. In 8 (0,5%) identified hemorrhoids while in 2 (0,1%) hyperplastic polyps, in 1 (0,05%) tubular adenomas, in 1 (0,05%) colon cancer is detected. In 10 (0,6%) were found to be normal colonoscopic findings.

discussion

Therefore, family physicians working in prisons, do precisely defined tasks in family medicine and triple protocol provisions of regulations while avoiding unnecessary referrals to allow granting effective health care; will protect the doctor from legal point of view. In prisons, it is necessary to do the screening tests for early diagnosis and treatment of major diseases.

Assessment of anxiety, problem solving and personality traits of the patients who were admitted to smoking cessation clinic

Özlem Büyükçiçek¹, Yarkin Özenli², Kenan Topal¹, Nurgül Bozkurt³, Önder Tuğal², Çiğdem Gereklioğlu⁴

¹Adana Numune Training and Research Hospital, Department of Family Medicine, Adana/Turkey

²Adana Numune Training and Research Hospital, Department of Psychiatry, Adana/Turkey

³Denizli State Hospital Chest Diseases Clinic, Denizli, Turkey

⁴Baskent University Medical Faculty, Department of Family Medicine, Ankara/Turkey

BACKGROUND: Smoking is among the major causes of fatal diseases. The difficulty of smoking cessation is assumed to arise from genetic and environmental factors beside the psychopharmacologic effects of nicotine. Socioeconomic status and personality traits have not been investigated intensively. We aimed to investigate anxiety, problem solving ability, personality traits and their relationship with nicotine addiction level in smokers.

MATERIAL-METHOD: This cross-sectional case-control study was conducted with 132 patients and 126 volunteers. State-Trait Anxiety Inventory (STAI FORM TX-1, STAI FORM TX-2), Problem Solving Inventory (PSI), Eysenck Personality Inventory and Fagerström Test were used for assessments. Smokers were asked to fulfil the all tests, non-smokers did not fulfill Fagerström Test.

RESULTS: While mean age was 35.15±10.12 years for smokers, it was 36.93±11.27 for non-smokers. State anxiety scores were 43.7±4.9 and 45.1±5.3 for smokers and non-smokers, respectively (p=0.03). Trait anxiety scores were 48.9 ±6.2 and 46.3±4.7 for smokers and non-smokers, respectively (p=0.000). Mean Fagerström test score was 5.04±2.81 for smokers. Mean Problem Solving Inventory score was 113.9±26.6, and 96.1±29.8, respectively for smokers and nonsmokers (p=0.000). The mean score of neuroticism was 3.52 ± 1.80 and 2.21±1.77 for smokers and non-smokers, respectively (p=0.000). Mean score of psychoticism was higher among smokers (1.93±1.37 vs 1.48±1.29, p=0.008). There was no statistically significant difference between groups in terms of extraversion (p=0.71). Mean score of lying was 3.85±1.50 and 4.30±1.35 for smokers and non-smokers (p>0.80).

CONCLUSION: It is not a reasonable approach to focus on only the organic diseases in nicotine addiction. Psychiatric examination, psychological tests should be performed and the disorders should be treated. In this context, it is important to follow a holistic, biopsychosocial approach and provide psychiatric support. Our study reveals the need for adopting a multidisciplinary approach in treatment of nicotine addiction.

P-1051**Prevalence of functional dyspepsia and associated psychological factors, in the urban area of Leon Municipality, Nicaragua. A Community Based Study 2003 – 2004**Edgar Martin Peña¹, Nawi Ng², Douglas R Morgan³¹Multiprofessional Teaching Unit of Family and Community Care-Zaragoza II Sector, Zaragoza, Spain. Centre for Epidemiology and Health Research, University of Nicaragua, León.²Unit of Epidemiology and Global Health Umeå University, Sweden³Department of Medicine, Vanderbilt University, Nashville, TN, USA. Department of Medicine, UNC Chapel Hill, NC, USA.

BACKGROUND: The diagnosis and classification of Functional Dyspepsia in the general population has been a focus of researchers since the 1980s. Nonetheless, there are few community-based studies on this issue, particularly in Latin America. **AIM:** To measure the prevalence of functional dyspepsia and to analyze the psychological factors associated with functional dyspepsia, in the urban area of Leon, Nicaragua. **METHODS:** The study design is a cross-sectional survey, with household interviews. It was conducted within a demographic and health surveillance system (DHSS) of the Leon Municipality, Nicaragua. A sample of 1617 inhabitants (18 to 65 years old) was randomly selected from the DHSS. Three different instruments were used: the Rome II modular questionnaire to measure Functional Dyspepsia, Harvard-Uppsala trauma questionnaire focused on posttraumatic stress, rape and war experience; and finally conflict tactic scales to determine domestic violence. Socioeconomic Status (SES) was measured with the poverty index based on unsatisfied basic needs. **RESULTS:** The prevalence of functional dyspepsia in the community was 11.6%, affecting more females (12.6%) than males (10.2%). Domestic violence was significantly associated with Functional Dyspepsia in the logistic regression model (OR: 1.61, IC95% 1.10, 2.37). **CONCLUSIONS:** The prevalence of Functional Dyspepsia was 11.6%. Domestic violence was identified as an important independent risk factors for functional dyspepsia our final logistic regression model. **ACKNOWLEDGEMENTS:** This study was supported by a grant from the Rome Foundation (DM). The study infrastructure was provided for by the Centro de Investigación en Demografía y Salud (CIDS, Center for Epidemiology and Health) of the University of Nicaragua, León, as a member of the global INDEPTH Network

NO								
Total	1617 (100.0)	962 (100.0)	655 (100.0)		813 (100.0)	352 (100.0)	452 (100.0)	

In statistical terms, women experienced more physical, emotional or sexual abuse (domestic violence) in comparison with men (p value < 0.001). Otherwise men have statistically significant relation with the war experience in relationship with women (p value < 0.001)

Association of functional dyspepsia with psychologic exposures, using univariate and logistic regression models of analysis.

Risk Factor	Functional dyspepsia		Univariate		LogReg Model	
	YES	NO	ORc	IC95%	ORadj	IC95%
Domestic Violence	NO	137	1181	1		1
	YES	51	248	1.72	1.18 - 2.49	1.61
Rape	NO	165	1312	1		1
	YES	23	117	1.56	0.97 - 2.51	1.52
War Experience	NO	167	1256	1		1
	YES	21	173	0.91	0.56 - 1.47	1.09
Poverty	NO	111	956	1		1
	YES	77	473	1.40	1.02 - 1.91	1.33

In our univariate model, FD was statistically associated only with domestic violence and poverty. The likelihood to have FD increased 72% with experience of domestic violence and 40% with poverty compared to without these conditions, after controlling for gender and age. We hypothesized that the self-reported experience of domestic violence, rape and war experience would be correlated with each other (multicollinearity). To know the existence of correlation influence between these variables we analyzed the applied variance inflation factor (VIF) and tolerance following for the logistic regression model. The results obtained in all variables were under 1.16 for VIF and above 0.86 for tolerance, showing little relationship between them. Therefore, we included all variables in the regression model adjusted by age and gender. The final result suggested that a person exposed to domestic violence was 61% more likely to develop FD compared to those who did not experience domestic violence, regardless of gender, age or other studied exposures.

The Evaluation Of The Patients Who Have Complaint with Headache Sociodemographic Features and Migraine Awareness

Selin Haliloğlu¹, Sefer Günaydın², [Seçil Arıca](#)¹

¹Department of Family Medicine, Haseki Education and Research Hospital, Istanbul, Turkey

²Department of Neurology, Haseki Education and Research Hospital, Istanbul, Turkey

AIM: Headache is a very common complaint and we wanted to analyze the relationship of the differences between migraine awareness, knowledge and sociodemographic features among the unresolved patients complaining from headache.

METHOD: We established a uniform survey which was filled by the same researcher. 105 patients were enrolled to obtain information about their sociodemographic profiles (age, sex, education level, marital status, occupation, salary), alcohol consumption and smoking, concomitant chronic diseases, quality of sleep, relatives with headache complaint, headache attack features (onset and the attack periods) medications used before and

the patient knowledge about migraine. The patients who were diagnosed with migraine earlier were excluded from the survey.

RESULTS: 105 patients with headache complaints were enrolled in this research among whom 49 were males and 56 were females. The average age was 35.1 ± 11.3 . The patients claiming to have knowledge about migraine was 53.3 % (56) of the group. Among this group 21.4 % (12) claimed to get their knowledge from their family, 23.2 % (13) from friends, 26.8 % (15) by searching the web, 28.6 % (16) from their doctor. The patients who believed that neurology department was the right place to diagnose migraine and establish migraine awareness was 66.1 % (37) while 28.6 % (16) believed family medicine is the right place to do so. The most significant parameters in our survey are found to be age $p=0.026$, education level $p<0.001$ and pain period $p=0.001$ to analyse migraine awareness. The patients' knowledge level is decreased proportionally by age and in contrast increased with education level and pain period.

CONCLUSION: This research shows that migraine awareness is more common among the highly educated people with high socioeconomic positions in society. Gender does not make any difference about the awareness, however it is noticeable that there is no relation between age, sleep time and headache attack periods.

Results of infectious diseases screening in among prisoners

Suat Sincan¹, Zekeriya Aktürk², Abdulkadir Kaya², Kenan Taştan²

¹Atatürk University Student Health Center

²Ataturk University Medical Faculty Department of Family Medicine

Introduction

Given to the prison health services, the Ministry of Justice, the Ministry of Internal Affairs and the Ministry of Health signed together the 'Triple Protocol' which was implemented after the Health Transformation project in Turkey. Thus, according to the regulations and provisions of all tasks assigned to the tripartite protocol, family physicians should be employed in prisons. One of these tasks is screening of infectious diseases on risk groups.

Methods

We examined prisoners who stayed in Campus of Erzurum Prison. The study protocol has explained, those who accepted to participate in the study, filled the informed consent form. A questionnaire for demographic data were obtained. From the blood samples, hepatitis, syphilis, acquired immune deficiency syndrome markers were investigated in the Erzurum Public Health Laboratory. Hepatitis B vaccine was applied to those with the negative markers.

Results

We examined 1108 prisoners who stayed in Campus of Erzurum Prison. 967's (87,2%) no markers were positive. We were applied hepatitis B vaccine for those people. On 99 prisoners (8.9%), hepatitis B antibody have been identified. On 3 prisoners (0,3%) VDRL positivity was detected. On 29 prisoners (2.6%) were identified carriers of hepatitis B, on 7 prisoners (0,7%) hepatitis C positivity was detected. Hepatitis B carriers who were identified 17 cases (1.5%) were newly diagnosed. On 4 prisoners (0,4%), including two foreign nationals, acquired immunodeficiency syndrome have been identified.

Discussion

Prisoners can go to hospital only with a referral from a family physician. Therefore, family physicians working in prisons, do precisely defined tasks in family medicine and triple protocol provisions of regulations while avoiding unnecessary referrals to allow granting effective health care; will protect the doctor from legal point of view. In prisons, it is necessary to do the screening tests for early diagnosis and treatment of major diseases.

Osteoporosis in a Primary Health Care Unit

Nuno Namora, Maria João Abreu, Maria Inês Madureira, Tiago Ribeiro, Luísa Ferraz, Fernanda Rodrigues
USF DuoVida - ACES Alto Ave, Portugal

BACKGROUND: Osteoporosis is characterized by decreased bone mass and microarchitectural deterioration of bone, leading to increased risk of fracture. Osteoporotic fractures represent a major public health problem because of its high prevalence, medical consequences, decreased in quality of life and economic and social costs. Recent studies indicate that the prevalence of osteoporosis in Portugal is 10.2%.

AIM: Determine the prevalence and characterize the osteoporosis in the population of a primary care unit.

METHODOLOGY: Observational, descriptive, analytical and transversal study in adult patients of a primary care unit with the osteoporosis code (L95) of the International Classification of Primary Care - 2nd edition. Through consultation of the electronic health records in February 2015, the following variables were gathered: gender, age, body mass index (BMI), smoking, alcohol, diabetes mellitus, hypertension, previous fracture, DEXA and therapy. Statistical analysis was performed in SPSS.

RESULTS: The prevalence of osteoporosis was 0.45% (n = 68), with a mean age of 69 years. 89.7% patients with osteoporosis were female, 91.2 % were non-smokers and 8.8% had a previous fracture. The population average BMI was 28.6 kg/m². The average alcohol consumption was 52.97g/week. In terms of comorbidities, 10.3% were diabetic and 42.6% were hypertensive. DEXA was performed in 29.4% patients, 30% of which performed it within the last 5 years. In terms of DEXA results, 15% had normal criteria, 40% showed osteopenia and 45% had osteoporosis. With regard to therapy, in 61.8% of cases it was prescribed at least one bisphosphonate.

DISCUSSION: The prevalence of osteoporosis found is much lower than reported in the literature, which can be justified by the absence of medical records. It is therefore necessary to alert physicians to the correct fulfilment of diagnostic criteria. This will allow the General Practitioners a more direct intervention through pharmacological and non-pharmacological measures.

Serum alkaline phosphatase level as an early diagnostic tool in colorectal cancer

Bojan Zoran Pavkovic, Marina Slobodan Brankovic, Marija Marjan Zaric

Department of General Practice, Health Center "Dr Simo Milosevic"

Background&Aim

Serum alkaline phosphatase (ALP) levels is frequently elevated in patients with colorectal cancer (CRC). The significance of ALP as a predicting tool for CRC is not sufficiently well recognized.

The aim of study was to evaluate correlation between serum ALP levels as nonspecific blood test, fecal occult blood test (FOBT) as screening method for gastrointestinal bleeding, carcinoembryonic antigen (CEA) values as tumor marker and colonoscopy findings as final diagnostic procedure for CRC.

Method

The retrospective, observational study involved 151 patients, aged 50-74 years, whose medical records were reviewed and statistical analysis was done to evaluate the significance of ALP as predicting tool for CRC.

Results

A total of 151 patients were divided into two groups.

Observed population consisted of 73 patients, 41 females (56%) and 32 males (44%), who underwent colonoscopy which revealed the existence of tumor masses, and pathological findings confirmed malignancy.

Control group consisted of 78 patients, 42 females (54%) and 36 males (46%), from the general population, all without confirmed malignancy.

For a period of six months before further diagnostic procedures increased levels of ALP were recorded in 39 patients (53%) in observed population and in 13 patients (17%) in control group. There was statistically significant difference ($p < 0.005$).

CEA levels were elevated in 25 patients (34%) before colonoscopy is performed.

It was found that 23 patients (92%) with elevated levels of CEA had also increased levels of ALP.

FOBT was positive in 70 patients (96%), and in all who had increased levels of ALP.

Conclusions

Increased levels of serum ALP is associated with CRC. It is nonspecific blood test, but should arouse suspicion of CRC among other pathologic entities.

It is advisable to use of serum ALP levels as early diagnostic predicting tool for CRC, because it is a simple, low cost and relatively sensitive method.

Modern management of severe knee osteoarthritis with low power lasertherapy(L.L.L.T) associated with local steroid infiltration versus conventional therapy by GPs

Mihai Sorin Iacob, Sorina Saftescu, Adriana Carpinisan

Department of Family Medicine, Advitam Medicis Medical Center, Timisoara, Romania.

BACKGROUND: Knee osteoarthritis is a degenerative arthropathy, progressive, disabling, affecting elders, characterized by degradation of joint cartilage, bone remodeling and inflammatory changes in the synovial membrane. This study aims to present the results of LLLT, with red and infrared emission with 1800mW in comparison with classic therapy.

METHOD: We conducted a prospective, randomized, controlled study over three years, on 450 patients, using two laser devices. Imaging (US, MRI, x-ray), along with biomarkers were performed to make an accurate and fast diagnosis.

Inclusion criteria were: obese patients older than 60 years, with moderate / severe knee osteoarthritis, documented on X-Ray:II-III grade by Kellgren-Lawrence Scale.

Exclusion criteria were: other comorbidities with organ failure, diabetes, malignancies, fracture history, treatment with systemic corticosteroids, anticoagulants.

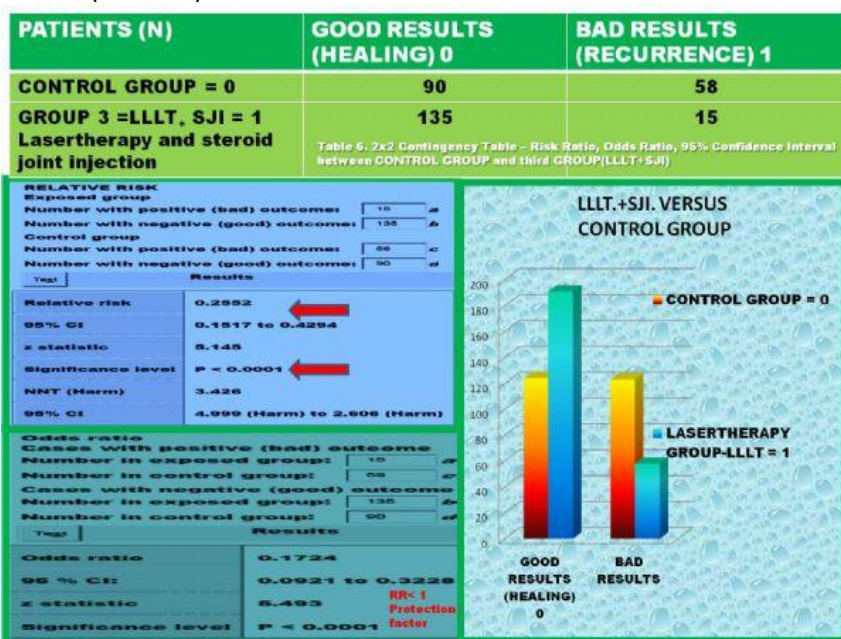

Cases studied were divided randomly into three groups: first - the Control Group received only conventional therapy: NSAIDs and analgesics, second includes patients treated with lasertherapy LLLT and third includes patients treated with local steroid infiltration associated with lasertherapy. The therapeutic protocol that we followed were: LLLT radiation density 4 - 10 J/cm², pulsed emission 9 Hz, IR spectrum radiation 870 nm and for joint infiltration we used Dexamethasone 4mg/ml with five exposures.

RESULTS: Elements evaluated in each patient before and after treatment were: pain on a Visual Analogue Scale (VAS), motion functional Scale, joint mobility, the quality of life, radiological changes. Our cure rates were: 60% in the first, 70% in the second and 90% in the third group of patients, with appreciation of personal satisfaction between 7 and 10 and significant reduction of pain, p<0,001, Relative Risk 0,40(Benefit), 95%CI 0,27 to 0,59, Odds Ratio 0,25 for exposed group with LLLT.

CONCLUSIONS: The combination of LLLT with steroid infiltration significantly improved outcome by 30% compared to those treated conventional. Laser therapy treatment is non-invasive, painless and shows excellent tolerance.

Heart Failure in a Primary Care Population: What can we improve?

Maria João Abreu, Nuno Namora, Tiago Ribeiro, Maria Inês Madureira, Fernanda Rodrigues, Luísa Ferraz
USF Duovida - ACES do Alto Ave, Guimarães, Portugal

BACKGROUND: Heart failure (HF) is a disorder with increasing prevalence in recent decades, associated with high morbidity and mortality. According the EPICA study, the estimated overall prevalence of HF in the Portuguese population was 4.4%, with a marked increase with age.

AIM: Determine the prevalence and characterize the HF in the population of a primary care unit.

METHODS: Observational, descriptive and retrospective study in adult patients of a primary care unit with the HF code (K77) of the International Classification of Primary Care - 2nd edition. Data was obtained by consulting the electronic health record in February 2015 to characterize the population about: gender, age, body mass index (BMI), alcohol abuse, medical comorbidities, echocardiography (date of the last) and therapy. Statistical analysis was performed in SPSS.

RESULTS: 139 cases were considered with the diagnosis of HF, so the prevalence of this disease was 1,3%. The mean age was 74.5±14.0 years, with a predominance of female (59,4%). The population average BMI was 28.6±5.9 kg/m² and alcohol (g for week) was 100.6 ± 137.3. About 75% of patients had a history of hypertension, 23% had diabetes mellitus, 25% had atrial fibrillation, 12% history of stroke and 9% had myocardial infarction. It was found that 69.9% (n=93) of patients had registered echocardiography, and 72% (n=67) of these had echocardiography in the last 5 years. About therapy, in 82.7% (n=110) of patients were prescribed a modulator of the renin-angiotensin system. Diuretics were prescribed in 75.2% (n=100) and beta-blockers in 43.6% (n=58) of the patients.

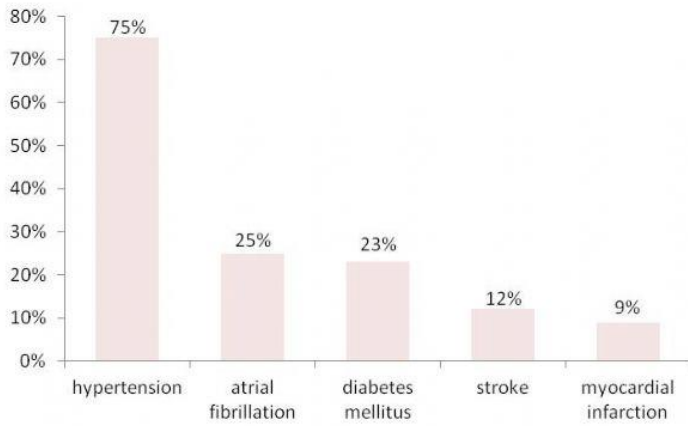

CONCLUSION: It was found that the prevalence of HF is lower than reported in the literature, which can be justified by the absence of clinical records. The General Practitioners have an important role in the early diagnosis of this disorder, thus reducing the morbidity and mortality associated with it.

Medical Relief in Malaysia: Examining the experiences of medical volunteers in the recent flood disaster relief management and their burnout rates. (Study protocol)

Nurainul Hana Shamsuddin¹, Aneesa Abd Rashid¹, Hani Syahida Salim¹, Siti Zulaikha Zakariah¹, Mohammad Ikram Mohd Salleh², Abdul Rashid Abdul Rahman³

¹Department of Family Medicine, Faculty of Medicine & Health Science, University Putra Malaysia

²Cyberjaya University College of Medical Sciences

³Malaysian Institute for Graduate & Higher Training (MIGHTy)

There are many Non-Governmental Organisation (NGOs) involved with flood relief projects to help the current existing resources available in Malaysia. NGOs have been involved in many aspect of relief including medical relief. The last 2 years of flood events in Malaysia were exceptionally larger in magnitude compared to previous flood events in the past decades. Therefore the effort in providing medical relief to flood victims recently had prevailed problems as we lack experience in coordinating large scale relief locally. Hence, we plan to bridge this gap by exploring experiences of volunteer health care providers involved in this process. As a number of the volunteers are involved repeatedly, we to determine if there is burnout amongst them. The main objectives of this study are to explore the views and experiences of health care provider volunteers involved in the recent flood disaster relief in Malaysia and to determine whether burnout is prevalent among medical volunteers in the recent flood disaster relief in Malaysia. The exploratory objectives would be done as a qualitative study, where as the burnout prevalence would be determined through a cross-sectional study using a validated questionnaire, the Maslach Burnout Inventory.

The qualitative arm would be carried out through focus group discussions and in-depth interviews. This study will be carried out at the states where the HCP volunteers reside, either from the affected states or others during the recent flood. Expected outcomes are knowledge regarding the experiences, contributions, and preparedness of health care provider volunteers involved in the recent flood disaster relief in Malaysia, their challenges and unmet needs and the prevalence of burnout amongst health care provider volunteers in medical relief in the NGOs. This knowledge will further be used to improve accessibility and efficiency of medical relief in future disaster management, which in turn would be more cost-effective.

Why have outpatients visited a family doctor and attended regular outpatients and why have regular outpatients terminated to visit a family doctor ?

Shin Matsumura, Tadao Okada

Department of Family Medicine, Tessyokai Kameda Family Clinic Tateyama, Japan

Background & Aim

However, continuity of care are known as one of the five key principles of primary care, it sometimes comes to an end. I try to reveal the reason why regular outpatients terminated to visit a family doctor by analyzing 3 year of medical chart.

Method

A retrospective chart review was conducted in outpatients from 1 Apr 2012 to 12 Mar 2015. The main outcome measures were the status and period.

Results

1954 charts were reviewed, total number of patients were 5044 and counting as there is no overlap outpatients were 1954. 271 patients attended regular outpatients and 168 patients have still continued to visit now. 103 patients terminate regular outpatients and 44 patients did at their reasons, 7 patients did at doctor's reasons, and 52 patients did by agreement. Some did not come to reservation because of cerebral infarction etc. by looking

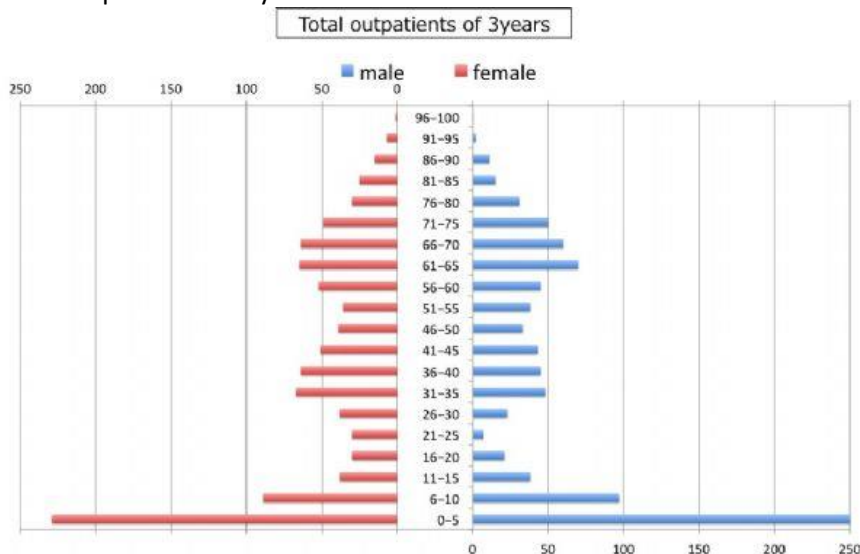

back later.

Conclusions

Half of regular outpatients terminated by agreement and some resumed as regular outpatients. I thought termination because of outpatients, there were compelling reasons by looking later. I might have maintained more continuity of care through the intervention such as letters or making a phone call to know the circumstances at that time.

¹Diabetes Center, Tzanio General Hospital, Piraeus, Greece

²Cardiology Department, Tzanio General Hospital, Piraeus, Greece

AIMS

This prospective observational study focuses on the biomarkers and the echocardiographic findings that could predict the new onset of LVDD on type 2 diabetes patients

MATERIALS & METHODS

We enrolled 48 volunteers (26 males) with type 2 diabetes of mean age 55.4 ± 10.0 years, mean HbA1c $7.5 \pm 1.5\%$, mean BMI 29.4 ± 5.1 Kg/m² and mean diabetes duration 2.8 ± 0.8 years with normal both systolic and diastolic cardiac function. We collected demographic, clinical and laboratory data and performed echocardiographic evaluation to each participant. Fasting plasma was drawn for BNP, sST2 and hs-CRP measurements. This procedure was repeated every 12 months for a 48-month time period.

RESULTS

At baseline: 41.7% of recruits had arterial hypertension, 45.8% dyslipidemia, 45.8% smoking. On metformin therapy was the 91.7% while 27.1 on SU, 8.3% on DPP-4 inhibitors, 8.3% on glinides and 4.2% on insulin therapy. Among the anti-hypertensives, 18.8% was on ACE-inhibitors, 16.7% ARB's, 4.2% HCT and 4.2% b-blockers. At the end of the study 28 subjects had LVDD. Univariate analysis showed that the presence of LVDD was related with: BMI ($p=0.05$), therapy with ARB's ($p=0.05$), hs-CRP ($p=0.02$), HDL-C ($p=0.03$), fasting triglycerides ($p=0.003$) and Left Ventricular Myocardial Index (LVMI) ($p=0.03$). No correlation was observed between LVDD and sex, age, diabetes duration, history of hypertension, dyslipidemia, smoking habits, oral antihyperglycemic agents, ESR, fibrinogen, total cholesterol, LDL-C, uric acid, BNP and sST2. Logarithmic regression analysis revealed that the new onset of LVDD was positively correlated with hs-CRP levels ($p=0.02$) and fasting triglycerides ($p=0.02$) and negatively with the therapy with ARB's ($p=0.05$)

CONCLUSIONS

Higher hs-CRP levels and fasting triglycerides may predict the new onset of LVDD – the echocardiographic depiction of diabetic cardiomyopathy - in type 2 diabetes patients with normal cardiac function, while therapy with ARB's may play a protective role in this 4-year prospective study.

4DSQ scores in a random sample of Turkish women and related factors

Gamze Şenol¹, Nurver Turfaner Sipahioğlu², Suphi Vehid³, Fikret Sipahioğlu⁴

¹As. Dr. Department of Family Medicine, Cerrahpasa Medical Faculty, Istanbul University, 34303

²Assoc. Prof. Department of Family Medicine, Cerrahpasa Medical Faculty, Istanbul University, 34303, Istanbul, Turkey

³Assoc. Prof. Department of Public Health, Cerrahpasa Medical Faculty, Istanbul University, 34303

⁴Prof. Dr. Department of Internal Medicine, Cerrahpasa Medical Faculty, Istanbul University, 34303

AIM: The aim of this study was to analyze depression-anxiety-distress and somatization levels with 4DSQ scale in a random sample of Turkish women and search its relationship with their demographic data.

MATERIAL-METHOD: The study group consisted of 106 women with mean age 52±15.23. Turkish version of 4DSQ scale was applied to all participants and their demographic data were questioned. The results were analyzed with SPSS 21 using one-way anova, chi-square and student-t test.

RESULTS: Demographic factors related with depression were; age (p=0.046), BMI (p=0.012), menopause duration (p=0.023), time after marriage (p=0.017), diabetes (p=0.042), employment (p=0.008), treatment (p=0.012), education (p=0.006) and consuming dairy products (p=0.004). Demographic factors related with distress were; BMI (p=0.058), hyperlipidemia (p=0.056), rheumatologic diseases (p=0.069), neurologic diseases (p=0.036) and education (p=0.058). Demographic factors related with somatization were; age (p=0.057), menarcheal age (p=0.005), time after marriage (p=0.021), smoking (p=0.003), number of packages (p=0.026), number of births (p=0.018), employment (p=0.045), cardiac diseases (p=0.003), hypertension (p=0.016), thyroid diseases (p=0.048), treatment (p=0.001) and consuming protein (p=0.045). Demographic factors related with anxiety were; smoking (p=0.002), number of packages (p=0.001), cardiac diseases (p=0.005), menopause duration (p=0.038).

CONCLUSION: Smoking was related with anxiety and somatization, employment was related with somatization and depression, education level was related with depression and menopause duration was related with depression and anxiety, time after marriage was related with depression and somatization and age, BMI and education were related with depression.

"{" The effect of cigarette on diabetic complications "}"

Orhan Yılmaz¹, Zuhal Aydan Sağlam¹, Kaan Güngör²

¹Istanbul Medeniyet University Göztepe Training and Research Hospital; Department of Family Medicine

²Istanbul Medeniyet University Göztepe Training and Research Hospital; Department of Endocrinology

GOAL: Cigarette is one of the alterable risk factor of many diseases especially cardiovascular disorder and cancer. Cigarette increases micro and macrovascular complications on diabetic patients by damaging endothelial functions. The aim of our study is to assess the effect of cigarette on diabetic complications in a small-scaled group of patients.

METHOD: This study was practised on November-December 2014 as a cross-sectional analytic at Diabetes polyclinic of İstanbul Medeniyet University Göztepe Training and Research Hospital. Voluntary patients who are 18 or older with type-2 diabetes applied to the Diabetes polyclinic and smoking and non-smoking patients were compared in terms of demographic, metabolic features and complication frequency. The description of regulation was acknowledged as HbA1c≤%7. The analysis of the data was fulfilled by using frequency, chi square and t-test. P<0.05 was acknowledged as significant.

FINDINGS: Demographic features and complication rates of 206 patients suffering type-2 Diabetes Mellitus who were involved in the study can be seen on Table 1. Smoking habit of men was significantly high (p=0,000). Both groups differed in terms of diabetes age, average HbA1c and utilization of insulin (p=0,000). Considering the factors of microvascular and macrovascular complications, there were no differences between those who smoke and who do not (p=0.28; p=0.92). Not surprisingly, micro and macro complications increased on those who smoke

and who do not as the diabetes age increased ($p=0.018$; $p=0.020$). There were more frequent microvascular complications on smoking women than men($p=0.007$).

RESULT: Our study claims that cigarette has no effect on micro and macrovascular complications. Besides, microvascular complications were more frequent on women who smoke. The reason we cannot show the effect of cigarette on complications may be lack of sufficient time or patient. Moreover, we need more patients and extended studies in order to answer why microvascular complications are observed more frequently on women.

The importance of COPD screening methods in Primary Care

Madalina Daniela Graure, Alexandru Claudiu Coman, Juana Flores Torrecillas, Florentina Guillen Cavas
Cartagena Casco Antiguo Health Center, Cartagena, Murcia, Spain

• Background & Aim

COPD is usually diagnosed in advanced phases when secondary complications appear. Most of the medical care of these patients takes place in General Practice, therefore it is important to establish preventive activities from the beginning to reduce the long term complications.

Microspirometry is a rapid and easy method to diagnose decreased pulmonary function with results comparable to classic spirometry.

Our main objective is to detect COPD in adult patients who smoke or had smoked, using microspirometry, COPD Diagnostic Questionnaire (CDQ) and COPD-PS.

• Method

Patients included in the study are aged 35 to 75 and are active or ex-smokers (≥ 10 pack years). Those diagnosed with COPD, asthma or with a history of respiratory infection in the last 4 weeks are excluded.

The calculated sample size is 370 (confidence level of 95%, 5% precision rate, estimated loss 5%).

For collecting data we are using opportunistic sampling methods.

Once selected the patients, they will have to complete the two questionnaires. Microspirometry will be performed using the Vitalograph COPD-6 microspirometer in those who obtain more than 4 points in the COPD-PS and/or 17 points in CDQ. Those who obtain a $FEV_1/FEV_6 < 0.7$ will be diagnosed as possible COPD.

The possible COPD patients will be referred to the Pneumology Department for confirmation.

Variables: gender, age, pack-years, result COPD-PS, result CDQ, FEV_1/FEV_6 . Data will be processed in SPSS-18.0 using univariate and bivariate analysis techniques.

• Results

The results obtained by now show that microspirometry is a valid method for diagnosing COPD at its early stages thus early treatment can be considered also increasing the chance of smoking cessation.

• Conclusions

We hope that with this study we will demonstrate the benefits of early diagnosis of COPD in General Practice by using microspirometry.

The impact of the economic crisis on the organization, implemetation and programming of vaccination in infancy and childhood

Maria Gianniki, Michail Migkos, Maria Bakola, Konstantina Mavridou, Paraskevi Voulgari, Alexandros Drosos
Rheumatology Clinic, Department of Internal Medicine, Medical School, University of Ioannina, Ioannina, Greece.

Background & AIM: The worsening economic problems has brought effects on social and health level. The world faces the challenge to prevent the economic crisis becoming a social and a health crisis. The aim of this study is to defend the vaccination which should stay unaffected by the economic crisis.

METHOD: In the current study it has been conducted a combination of primary and secondary research. Secondary research is a literature review of authoritative scientific sources and legislation. The primary research was conducted through interviews with standardized questionnaires addressed to Health officers.

RESULTS: On the administrative level, fundamental reform is the amendment, which provides free supply and administration of vaccines in public structures to the uninsured. Despite the economic crisis, vaccination coverage of children in Greece remains at satisfactory levels. However, problems occur in covering specific vaccines such as repetitive doses of MMR, DTaP and polio. Also, delay is observed in performing pneumococcal, meningococcal, hepatitis B and HPV vaccines. Problems still exist in the coverage of special population groups (migrants, Roma). As a corollary of the above is the resurgence of diseases such as tuberculosis, meningococemia, pneumococcal respiratory infections, diseases which can be prevented by immunization. Vaccination coverage and the vaccination itself are directly related to demographic and socioeconomic factors (uninsured, unemployed, young age parents with many children(>3) and immigrants). Finally, is observed an increase of visits in outpatients clinics on public structures, which is directly correlated with the reduction in the percentage of families addressed now, in the midst of crisis, only in private pediatrician for childhood vaccination.

CONCLUSIONS: The economic crisis has adverse effects on the implementation of the immunization program, which are not recorded in their entirety, because immunization is a long process. The entirety of these effects will be the subject of reflection in the future.

Trends in peptic ulcer and gastro-oesophageal reflux disease registered in primary care and consecutive drug utilization in Croatia, 2005-2013

Vlatka Topolovec Nižetić

Foundation for the development of family medicine in Croatia

Background & aims

In daily practice we witness increase of utilization of drugs for peptic ulcer (PU) and gastro-oesophageal reflux disease (GERD). H₂-receptor antagonists (H₂RA) and proton pump inhibitors (PPI) have revolutionized the treatment of both groups of diseases. Aim of this study was to investigate if the trends of the consecutive drug utilisations were following the morbidity trends of PU and GERD registered in Croatian primary care (PC).

Methods

The study is observational and longitudinal, based on routinely collected data. The main sources of data collection were Croatian Health Service Yearbooks and annual reports of Agency for Medicinal Products and Medical Devices (HALMED), 2005 - 2013. We extracted the morbidity data related to the K diagnoses (ICD-X), number and structure of the registered diagnoses. From the HALMED Reports we obtained the data about the usage of the H₂RA and PPI drugs, types of drugs (ATC classification index) and amount expressed in DDD/TID.

Results

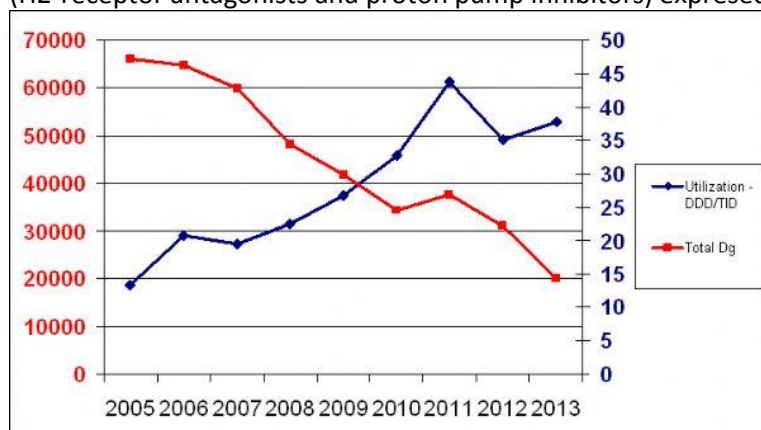

Number of PU and GERD diagnosis is in continuous decline, with the exception of year 2011 when it has slightly increased. Over the observed period, a number of diagnoses have declined by 70%, from 65,942 diagnoses registered in 2005 to 20,039 diagnoses in 2013. Overall utilization of H₂RA and PPI drugs has been increasing. Overall increase in the observed period was 183%, from 13.33 DDD/TID in 2005 to 37.72 in 2013. Utilization of H₂RA has increased by 34%, while utilization of PPI has increased by 345%.

Conclusions

The obtained results clearly indicated that the H₂RA and PPI drugs utilisation is not in association with the morbidity trends of PU and GERD registered in Croatian primary care. It could only be explained by utilization of those drugs in patients who use NSRI and other who are poly-medicated because of multi-morbidities, but further research are needed.

Clinical characteristics and survival in polymedicated elderly patients

Ricardo Enrique Reolid Martínez¹, Inmaculada Hernández Cerón¹, Marta Martínez Ruiz², Ana Belén Sánchez López³, Gema María Tello Nieves³, María Candelaria Ayuso Raya¹, Remedios Martínez Carmona³, Ignacio Párraga Martínez³

¹Albacete Area IV Health Centre, Health Care Service of Castilla-La Mancha, C/Seminario 4, 02006 Albacete, Spain

²Albacete Area V-B Health Centre, Health Care Service of Castilla-La Mancha, C/Profesor Macedonio Jiménez s/n, 02006 Albacete, Spain.

³La Roda Health Centre, Health Care Service of Castilla-La Mancha, C/Mártires 63, 02630 La Roda, Albacete, Spain.

BACKGROUND AND AIM:

To describe the clinical characteristics of polymedicated elderly patients in Primary Care and analyze their survival estimated as a function of comorbidity.

METHOD:

Cross-sectional study made in six consultations of family medicine of four basic areas of health. 275 individuals \geq 65 years who consumed more than five drugs for at least six months were selected through consecutive sampling. Sociodemographic variables, cardiovascular risk factors, health problems (CIAP-2 classification), drug consumption and survival estimated by the Charlson comorbidity index (CCI) were collected. Descriptive, bivariate and multivariate (multiple linear regression) analyzes were performed.

RESULTS:

The mean age was 76.5 years (SD: 6.7). 55.6% suffered from more than five diseases. The most common health problems were endocrinological 93.8%, cardiovascular 92.0%, locomotive 57.8%, respiratory 25.8%, digestive 24.0% and psychological 22.3%. 85.8% had hypertension, 57.1% dyslipidemia and 41.1% diabetes. The average number of drugs consumed was 8.2. (SD: 2.1). The median survival estimated at 10 years by CCI was 24.4% (interquartile range, 1.1% -53.4%). Survival showed a statistically significant inverse correlation regarding the number of health problems ($r=-0,309$; $p<0,001$) and the number of drugs ($r=-0,285$, $p<0,001$). Through adjustment with a multiple linear regression model, the variables associated with increased survival estimated at 10 years were: younger age, female sex, less number of drugs consumed, and absence of ischemic heart disease, stroke, peripheral artery disease, heart failure, diabetes, digestive, respiratory and urological problems.

CONCLUSION:

The vast majority of polymedicated elderly patients have endocrine and cardiovascular diseases. More than half of them suffer from more than five pathologies. Survival in polymedicated elderly people is related with the variables included in the CCI as with others such as sex, number of drugs consumed and the presence of any Urological, digestive or respiratory problems.

Comparative Trial between High Intensity Lasertherapy (HILT) versus Low Power Lasertherapy (LLLT) associated with Trigger Point Injections in treatments of chronic low back pain

Mihai Sorin Iacob, Sorina Saftescu, Madalina Gligor

Department of Family Medicine, Advitam Medicis Medical Center, Timisoara, Romania.

In the GP practice, we often face with low back pain, that cause problems both, patients by long periods of inactivity and suffering, and physicians regarding management of this complex pathology. This study aims to present the results of LLLT, with red and infrared 685/830 nm wavelength with 1800 mW-power, compared with the results obtained after treatment with HILT in infrared emission 810/980 nm wavelength, 7W-power.

METHODS: Inclusion criteria were patients with chronic nonspecific back pain of various causes such as: degenerative vertebral joints and soft tissue disorders, or lumbar vertebral disk herniation with radiculopathy, but without neurological deficit without chronic diseases. We conducted a prospective study (RCT) over three years, on 750 patients, using two laser devices (semiconductor source). Steroid used in Trigger Point Injections (TPI) was Dexamethasone 4mg/ml. Cases studied were divided into three groups: First Group includes patients with classic medication, Second Group included patients treated with LLLT associated with TPI and Third Group included patients treated with HILT associated with TPI. Elements evaluated to each patient were: pain on a visual analogue scale (VAS) and a motion-functional scale (MFS) of the low back disability with scoring from 1 to 10.

RESULTS: Our healing rate was 48% in the first, 78%in second and 88%in third group with significant pain reduction. All these data, were entered in electronic database designed by us in Microsoft Access. Analysis of risk and data obtained on patients by: VAS and MFS scales, before and after treatment, within each group was compared by Student' t-test, $p<0,01$ and among all three groups after the final evaluation of patients by ANOVA, $p<0,001$.

CONCLUSION: The combination of HILT with steroid infiltration had significantly improved outcome with 40% compared to conventional therapy. HILT is proved to be more effective than LLLT in management of chronic low back pain.

Conclusions

Conclusion:

1. The combination of **HILT** with steroid infiltration had significantly improved outcome with 40% compared to conventional therapy and can be consider the treatment of LBP with best outcome.
2. **HILT** is proved to be more effective than **LLLT** in management of chronic low back pain combined with steroid TPI. ($p < 0,001$)

Association of Mean Platelet Volume levels with cardiometabolic parameters, neurological outcome and mortality in patients with ischemic stroke

Christos Verras, Angeliki Angelidi, Evangelos Fousteris, Athanasia Papazafeiropoulou, Georgios Kapsalakis, Chariklia Sagia, Froso Efstratiadis, Georgios Christofilidis, Asimina Ganotopoulou, Andreas Melidonis
Diabetes Center, Tzanio General Hospital, Piraeus, Greece

Introduction - Purpose

The Mean Platelet Volume (MPV), a morphological marker of platelets, has been associated with cardiovascular events and it is a potential predictor of increased mortality and adverse outcomes in people with cardiovascular disease. The purpose of this study is to investigate the possible association between MPV with cardiovascular risk factors as well as the neurological outcome and the length of hospitalization in patients with ischemic stroke.

Material and method

We studied 78 patients (55% men, 45% women) with a mean age: 75.7 ± 7.3 and 79.4 ± 6.8 for men and women respectively, hospitalized for ischemic stroke. Twenty-five patients had previously known or newly diagnosed atrial fibrillation (AF), 37 had diabetes mellitus (DM) while 29 were smokers.

Severity of neurological deficit according to the National Institutes of Health Stroke Scale (NIHSS) was estimated on admission and on discharge from the hospital.

Results

The MPV showed a positive association with the outcome (NIHSS admission and discharge score) in patients with AF ($p < 0.05$) as well as the presence of diabetes mellitus and NIHSS admission score of these patients ($p < 0.05$). Furthermore, MPV was positively associated with the duration of hospitalization (6.7 ± 3.1 , $p < 0.05$) and a borderline significant trend with smoking ($p < 0.10$). No correlation was found between MPV and other cardiovascular risk factors and mortality of patients.

Conclusions

High levels of MPV are associated with a worse outcome particularly in people with AF. Moreover, MPV levels are associated with a longer duration of hospitalization but not a higher incidence of mortality in patients with ischemic stroke.

Correlation between Fetuin-A with biomarkers in morbidly obese patients prior to and six months after bariatric surgery

Christos Verras¹, Yannis Simos², George Ayiomamitis³, Evangelos Fousteris¹, Athanasia Papazafeiropoulou¹, Spyridon Konitsiotis², Angelos Evangelou², Nikiforos Dimitrios Kiortsis², Andreas Melidonis¹

¹Diabetes Center, Tzanio General Hospital, Piraeus, Greece

²Laboratory of Physiology, Medical School of University of Ioannina, Ioannina, Greece

³2nd Surgical Department, Tzanio general Hospital, Piraeus, Greece

Background and aims

The liver secreted glycoprotein Fetuin-A has been recently associated with insulin resistance, atherosclerosis and obesity. The objective of this study is to examine any possible correlation between Fetuin-A with these biomarkers in morbidly obese patients prior to and six months after bariatric surgery.

Materials and methods

We recruited 20 morbidly obese patients (mean BMI: 43.0±3.0 kgr/m²) who were admitted to the surgery clinic of our hospital to undergo programmed bariatric surgery (laparoscopic sleeve gastrectomy). Forty percent of our sample was males and 20% had type 2 diabetes. Fasting blood samples collected before and 6 months after surgery were analyzed for glucose, HbA1c, lipidemic profile, hs-CRP, fibrinogen, insulin and Fetuin-A. We calculated HOMA-IR index and lipid accumulation product (LAP) to all participants. Bioelectric impedance was performed in all patients for the assessment for fat mass and fat free mass at baseline and at 6 month follow up.

Results

The mean body weight loss during the study period was 31.5±11.81 kgs, of which 25.54±21.48 Kgs were fat mass. Mean (±SD) serum Fetuin-A levels at baseline were 0.27 (±0.05) g/l which did not show difference compared to the 0.26 (±0.07) g/l of the follow up re-examination (p=0.808). Baseline Fetuin-A levels correlated with total cholesterol levels (r=0.582, p<0.05), LDL-cholesterol (r=0.540, p<0.05) and fat mass (r=-0.549, p<0.05) prior to bariatric surgery. No correlation was found with the rest of the study parameters at baseline. Follow up Fetuin-A levels did not show any correlation with any of the study parameters. The changes of Fetuin-A levels correlated with baseline triglycerides levels (r=0.592, p<0.01).

Conclusion

Our study demonstrated that Fetuin-A levels remained unchanged besides the significant weight loss achieved within the first 6 months after bariatric surgery, possibly indicating that this time period after the surgery is too short to reveal significant changes.

Does the sense of possession of basic professional competences have any effect on occurrence of burnout syndrome in family physicians?

Olgu Aygün¹, Vildan Mevsim²

¹Karabağlar 2 family health center

²Dokuz Eylül University, Medicine Faculty, Family Medicine Department

BACKGROUND:

Burnout syndrome is a major problem especially among health care workers. Many factors are known to be associated with this syndrome. Sense of individual skills and achievement are affected by one's education and competence in his/her professional practice. Higher the sense of individual skills and achievement, lower the occurrence of burnout syndrome.

Research question:

Does the sense of possession of basic professional competences have any effect on occurrence of burnout syndrome in family physicians?

METHOD:

This study is designed as a nested case-control study. Study population is physicians working in family health centres in Izmir. The sample was selected by cluster sampling method. Data were collected via a questionnaire consists of demographic variables and questions to measure sense of professional competences described by EURACT and Maslach Burnout Inventory Personal Achievement subscale (MBI-PA). Case and control groups were formed based on MBI scores. Student's t test, chi square test, correlation analysis and logistic regression analysis were used to analyse the data.

RESULTS:

There were 113 cases and 113 controls. Both groups were matched with respect to age and gender. Number of male and female participants was same for both of the groups; 64.6% male and 35.4% female. Mean ages of case and control groups were 44.7±6.9 and 44.8±6.8 respectively. MBI-PA scores were 23.04 for cases and 14.6 for controls. In case and control groups, the rates of physicians who have strong sense of competence were 36.3% and 84.1% respectively. Cases were more likely to participate postgraduate medical congresses and activities.

CONCLUSION:

Strong sense of competence is associated with low occurrence of burnout syndrome in primary care physicians. Postgraduate and continuous medical education is important in adoption of core competencies in primary care.

Long term changes of metabolic parameters in T1DM patients on the switch from MDII TO CSII with BMI categorization

Alexandros Kamaratos, Evangelos Fousteris, Christos Verras, Athanasia Papazafeiropoulou, Ioannis Bakalis, Vasiliki Liosi, Viktoria Katsouri, Parthenopi Alexandropoulou, Styliani Iraklianiou, Andreas Melidonis
Diabetes Center, Tzanio General Hospital, Piraeus, Greece

This study addresses the impact of continuous subcutaneous insulin infusion (CSII) on each BMI category of type 1 diabetes patients under typical multiple daily insulin injections through a 3-year prospective follow up period. We compare the effectiveness of CSII on each BMI category as long as it concerns glycemic control, frequency of hypoglycaemia and needs of insulin units per day, given the fact that possible insulin resistance might alter the results as BMI rises.

81 patients with T1DM treated with multiple daily insulin injections were finally recruited after signed informed consent. We documented detailed medical history, clinical and laboratory findings for each participant before the launch of CSII and each year later on for 3 consecutive years. For statistical analysis we divided the study population according to their BMI: Group A: BMI<18,5: underweight, Group B: 18,5<BMI<25: Normal, Group C: 25<BMI<30: Overweight, Group D: BMI>30: Obese.

81 participants were divided into the 4 study groups: A: 2 patients, B: 40 patients, C: 25 patients and D: 14 patients. Except the group A, all the rest groups presented better glycemic control, within the first year of follow up which maintained throw-out the total follow up period ($p<0.01$) without change of BMI. Lesser hypoglycemias were noticed even from the first year after CSII especially for groups B & D ($p<0.01$). All study groups preserved initial basal insulin rate at first year but reduction was noticed for 2nd and 3rd year of re-examination.

This study is the first to show the impact of switch from MDII to CSII on a Greek cohort of type 2 diabetes patients according to BMI category. CSII ameliorates rapidly and safely the glycemic control of type 1 diabetes patients regardless the BMI category of each patient. Hypoglycemic events were significantly reduced in normal weight and obese patients.

Health information on TV shows and health literacy in primary care patients with coronary heart disease; a descriptive survey in two districts of Istanbul

Berk Barış Özmen¹, Tahir Koray Yozgatlı¹, Ilayda Dalgakıran¹, Pınar Topsever²

¹School of Medicine, Medical Student, Acibadem University, Istanbul, Turkey

²Department of Family Medicine, Acibadem University, Istanbul, Turkey

INTRODUCTION: Television (TV) shows have a profound effect in people's lives, these elements in everyday life also play a critical role in the perception of health and are able to affect health literacy among individuals. Health literacy, in turn, may change the course of a disease by benefitting patient compliance and disease coping process. Patients with a chronic disease (coronary heart disease (CHD)) are targeted for this study, which aims to identify habits, attitudes and beliefs about TV shows containing health information, as well as, health literacy level.

METHOD: A descriptive survey study will be carried out in family health centres enrolling 150 coronary artery patients aged 40-65. Except for sociodemographic and health related information, patients will be asked about their habits regarding watching TV health shows and their attitudes and beliefs about credibility of health information sources via a survey designed by the researchers. Health literacy will be assessed by the Turkish versions of REALM and NVS tests. The data gathered will be analyzed with a quantitative method to identify possible relationship of exposure to health information on TV shows and health literacy in primary care patients with CHD.

RESULTS: Preliminary results of the study will be presented during the conference.

The role of soluble ST2 and the correlation between of inflammatory and biochemical markers in morbid obesity

Christos Verras¹, Athanasia Papazafeiropoulou¹, George Ayiomamitis², Evangelos Fousteris¹, Panagiota Spyropoulou³, Spyridon Matsagos³, Spyridon Konitsiotis⁴, Angelos Evangelou⁴, Dimitrios Nikiforos Kiortsis⁴, Andreas Melidonis¹

¹Diabetes Center, Tzanio General Hospital, Piraeus, Greece

²2nd Surgical Department, Tzanio general Hospital, Piraeus, Greece

³Blood Bank Service, Tzanio General Hospital of Piraeus, Greece

⁴Laboratory of Physiology, Medical School of University of Ioannina, Ioannina, Greece

Background & Aims

Obesity is associated with various metabolic pathways by chronic low-grade inflammation of adipose tissue and the related cardiovascular encumbrance, by acceleration the process of atherosclerosis. In the present study we study the correlation of the new ST2 inflammatory marker (soluble ST2) with classical inflammatory and biochemical markers in morbidly obese individuals.

Materials & Methods

We recruited 35 obese persons [23 female /12 male, middle aged (\pm SD): 38.9 ± 10.4 years, 42 ± 4 Kg/m² BMI]. Medical history and demographic characteristics as well as measurement of the levels of soluble ST2 were documented for all participants. The 28.6% of participants in the study had type 2 diabetes, 25.7% arterial hypertension, 31.4% dyslipidemia, 11.4% chronic obstructive pulmonary disease (COPD), while the 51,4% were smokers.

Results

The value of soluble ST2 (\pm SD) of the participants was 13.9 ± 4.2 ng/mL higher than reference values of healthy results supplied by the manufacturer of the kit. Multivariable analysis of the results showed that the levels of soluble ST2 were positively related with the presence of COPD ($p = 0.01$), the number of white blood cells ($p =$

0.02), the levels of SGOT ($p = 0.04$) and waistlines ($p = 0.02$) and negatively with the INR ($p = 0.01$) and TSH levels ($p = 0.05$). There were no statistically significant correlations with age, sex, presence of diabetes, arterial hypertension, smoking, BMI, waist circumference, mass of adipose tissue, the levels of HbA1c, fibrinogen, hs-CRP, plasma lipids and other indicators of liver biochemistry.

Conclusions

Increased levels of soluble ST2 of morbidly obese patients seem to be associated with increased waist circumference. The correlation was not confirmed with classical parameters of inflammation, such as hs-CRP and biochemical indicators such as the lipid profile. Further research on this field with larger populations need to be done.

Effect of levonorgestrel-releasing intrauterine system on cardiovascular risk factors

Ana Paula Fonseca, Isa Cruz, Márcia Soares

USF Cruz de Celas, Coimbra, Portugal

Background and Aim

The levonorgestrel-releasing intrauterine system (LNG-IUS) is an effective and long-term reversible contraceptive. Currently, it has gained importance in perimenopausal women. Concerns remain that progestin absorbed systemically from the device can aggravate the cardiovascular risk. The aim of this study was to compare cardiovascular parameters between 2 groups: women using LNG-IUS and women using nonhormonal intrauterine devices.

Method

We designed an analytic study of a retrospective cohort of woman using intrauterine devices on a primary care unit. Exclusion criteria was hypertension, diabetes, dyslipidemia, thyroid dysfunction, menopause and women without analytic control. Study variables: cholesterol, diastolic and systolic blood pressure, glucose, corporal mass index (CMI), age, tabagism and time since device introduction. Statistical analysis was performed by using SPSS 21. Descriptive statistics are shown as mean \pm standard deviation. We used t-test to investigate the differences between both groups and we considered as statistically significant when $p < 0.05$.

Results

Fifty women were enrolled: 26 using LNG-IUS and 29 using nonhormonal intrauterine system. Mean age was 41.9 ± 6.4 years, CMI was 24.1 ± 3.9 Kg/cm², 18% were smokers and the evaluations were performed 3.0 ± 1.5 years after the insertion of intrauterine device.

No statistically differences were observed between the levels of cholesterol, blood pressure and glucose. However, levels of systolic blood pressure, glucose, total and LDL cholesterol were higher in the hormonal device group.

Conclusions

We admit the existence of type I and II errors.

In our study, the use of LNG-IUS was not associated with adverse effects on cardiovascular factors. However, further studies are needed to confirm these results.

P-1075**Evaluation of family care-givers' knowledge on warfarin in home care settings**

Nisa Solmaz, Feyza Çelik, Münevver Tulunay, Doğukan Doğruel, Mustafa Arslan Bircan, Cenk Aypak, Derya İren Akbıyık, Hülya Yıkılkan, Süleyman Görpelioğlu

Dışkapı Yıldırım Beyazıt Training and Research Hospital, Ankara, Turkey

Background&Aim

Warfarin is the most widely prescribed oral anticoagulant in the world. It has been shown that increasing patients' knowledge about warfarin usage via a structured education, lowers those side effects and leads to better outcomes. Therefore we aimed to determine warfarin education levels of family care-giver in our home care settings.

Method

We conducted this cross sectional study among care providers of patients (n=80) who have been followed up by Dışkapı Yıldırım Beyazıt Research Hospital Home Care Service. We obtained information via phone call if those care-givers had received education about warfarin from medical professionals. We collected the data about age, sex, all prescribed drugs, underlying disease, last three months INR (International Normalized Ratio) values, history of hemorrhage from medical records of home care service.

Results

There were 59(74%) women and 21(26%) men included in the study. The mean age was 76.1 ± 9.6 years. Warfarin associated hemorrhage was seen 16 (20%) of 80 patients during the last three months. Only sixteen (20%) care-givers have received an unstructured verbal warfarin education from a medical professional. There are no significant statistics in comparison between warfarin education group and control group regarding hemorrhage, INR monitoring frequency, therapeutic INR range weekly warfarin dose, in last three months period.

Conclusions

A huge investment of time and finances has been directed to optimising the outcomes of patients requiring oral anticoagulant therapy. Our findings have revealed that warfarin education of care givers of home-care patients who are among the most vulnerable population, is inadequate despite intense monitoring visits. A multidisciplinary and a real structured education program may improve family care-givers' warfarin knowledge and result in better anticoagulation control which leads to fewer visits and reduction in health care costs.

P-1076**Prevalence of peripheral arterial disease in patients smokers with diabetes mellitus – Study in a primary health care institution**

Sara Quelha, Felicidade Malheiro

USF Arca d'Água; ACeS Porto Oriental; Porto; Portugal

Background and AIM: Peripheral arterial disease (PAD) is characterized by atherosclerotic occlusion of the arteries of the lower limbs and is a marker of systemic vascular disease. Diabetes mellitus and smoking are the main risk factors for its development, and 2/3 of patients are asymptomatic. In diabetic patients the prevalence estimated vary between 10-40%, with maximum in the sixth and seventh decades of life. Clinical history and physical examination is sufficient for the diagnosis of PAD, with the ankle-brachial index (ABI) is performed in all patients with risk factors for heart disease. The aim of this study is to evaluate the prevalence of PAD by evaluating the ITB, in the institution's patients most at risk for developing the disease - diabetes, smoking, the sixth and seventh decades of life.

METHODS: Search the computer system MIM@UF, of all patients between 50 to 69 years with ICPC2 codes P17 (Tobacco Abuse) and T90 (Diabetes mellitus non-insulin dependent). Descriptive and analytical observational cross-sectional study.

RESULTS: Of the 44 evaluable patients, the reason for female gender: male was 1: 8 and the average age was 59 years; 61.4% of patients were asymptomatic and of these, 41% had PAD. Of patients with intermittent claudication 61.5% had PAD. Only 4 patients reported pain at rest. The average value of HbA1C was 7.5 g / dl. Of the 21 patients with abnormal ABI, more than half (52%) did not show any clinical complaints. Only 3 patients with PAD had no other risk factors or injury already established elsewhere.

CONCLUSIONS: The prevalence of PAD was 47.7%, with the majority of asymptomatic patients. This study allowed the early diagnosis of disease in diabetic patients smoking, reinforce teaching, stratify risk and intervene in the prevention of complications, particularly in the coronary and cerebral lesions.

Relationship between body mass index and estimated glomerular filtration rate

Bojan Zoran Pavkovic, Marija Marjan Zaric

Department of General Practice, Health Center "Dr Simo Milosevic"

Background & Aim

Obesity is significant risk factor for chronic kidney disease (CKD). Glomerular filtration rate (GFR) provides an excellent measure of renal function.

The aim of study was to determine the existence of possible links between body mass index (BMI) and renal function.

Method

BMI was calculated based on anthropological measurement of patients.

Renal function was evaluated by the estimated glomerular filtration rate (eGFR) using the Modification of Diet in Renal Disease (MDRD) study equation.

Data were collected during 2014 and statistical analysis was done using SPSS 19.0 software to evaluate the relationship between BMI and eGFR.

Results

The study included a total of 65 patients, 36 females and 29 males, aged 20-64 years, all without clinical history of diabetes mellitus, cardiovascular event or renal failure.

Subjects were divided into three groups according to BMI: normal weight ($18.5 \leq \text{BMI} \leq 24.9$), overweight ($25 \leq \text{BMI} \leq 29.9$) and obesity ($\text{BMI} \geq 30$).

Analysis showed statistically significant difference in eGFR between normal weight patients and both singly, overweight and obese patients ($p < 0.05$), but not between overweight and obese patients ($p > 0.05$).

It was found that normal weight patients had better renal function compared to both, overweight and obese patients.

Conclusions

Overweight and obesity are associated with decreased filtering capacity of kidneys.

In obese patients should always pay attention to renal function in order to prevent the occurrence of CKD.

Keywords: BMI, eGFR, chronic kidney disease

⁶Department of Department of Biophsica, Trakya University, Medical Faculty, Edirne, Turkey

AIM: The objectives of this study were to evaluate the relationship between hypertension and cognitive impairment, to identify risk factors associated to the development of cognitive impairment (zinc, copper, vitamin B12, folic acid, gender, age, body mass index, dyslipidemia).

METHODS: This study is a cross-sectional study and included total 90 participants as 30 normotensive (ages; 51,18±6,80) and 60 hypertensive subjects (ages; 53,83±7,71). All the participants underwent a standardized clinical assessment, which included a medical history, and physical and neurological examination together with the Mini Mental State Examination (MMSE) tests. Normal cognitive function was defined as MMSE >24. Zinc and Copper levels of serum were determined by a atomic absorbtion spectrophotometer with flame.

RESULTS: MMSE were found to be significantly lower in hypertension patients ($p<0.01$). Vitamin B12 level was observed to be significantly higher hypertension patients than control group ($p<0.01$). Trace elements status parameters; copper and zinc levels were no significant differences in hypertension patients than control group. In the >10 years hypertension group MMSE ($p<0.05$), vitamin B12 ($p<0.05$) and zinc ($p<0.05$) had significantly lower than <5 years hypertension patients. Vitamin B12 and zinc levels were significantly lower ($p<0.05$) in hypertension patients with cognitive impairment. A positive correlation were found between zinc and MMSE ($r=0.281$, $p<0.05$) and vitamin ($r=0.399$, $p<0.01$). Significant negative correlation was observed between zinc and diastolic hypertension ($r=-0.294$, $p<0.05$).

CONCLUSIONS: These results suggest that decreased zinc level can be relationship of cognitive decline in hypertension patients.

pattern of Pap smears among women attending primary health care centers and hospitals in al-mukalla city, Yemen

Rasha Saleh Bazighifan

Hadramout university-almukalla city-hadhramout-Yemen

INTRODUCTION: Pap smear test is one of the most important tests for women to detect cervical cancer in low socio-economic countries. Cervical cancer is considered preventable, as the premalignant stages can be detected by Pap smear examination. This study aimed to identify the pattern of cervical smears and the factors that affect them and compare them among women attending primary centers and hospitals thereby improving the women health in Al-mukalla city, Yemen.

METHODOLOGY: a cross - sectional study was carried out on women aged 18 years to 60 years were collected who had visit the Obstetrics and Gynecology Clinic at primary centers and hospitals. The data was collected by recording the answers in questionnaires and performing cervical smears by extended tip spatula, then the smears immersed in 96%alcohol solution and were sent for staining and reported by pathologist. Analysis was done by using the SPSS for Windows system version 20.

RESULTS: 10.5% of cervical smears were abnormal and classified as precursors of cervical cancer. Percentage of precursors of cervical cancer in hospitals was 13.7 %, while in primary health care centers was 7.1%. Three types of precursors of cervical cancer were diagnosed which were (ASCUS) 5 (23.8 %), (LSILs) 14 (66.7%) and (HSILs) 2 (9.5 %).

CONCLUSION: Yemeni women would accept having a Pap test if properly offered to them. the precursors of cervical cancer were present in our society with high prevalence. The older age (33 yrs. and more), multiparty more than 3, long use of oral hormonal contraceptive five years and more, increased sexual activity for husbands and clinical cervical lesions per vaginal examination are the predictors of intraepithelial neoplasia of cervix.

Evaluation of the knowledge and practices of primary care professionals in throne to approach alcohol: Study AlcoAP

Fernando Leiva Cepas, Esperanza María Romero Rodríguez, Adriana Cabello Chanfreut, José Cuevas Cruces, Joao Miguel Madeira Martins, Javier López Moreno, José Ángel Fernández García, Luis Ángel Pérula De Torres Teaching Unit of Family and Community Medicine of Córdoba, Andalusian Health Service, Junta de Andalucía, Spain

OBJECTIVES: To assess the knowledge, attitudes and practices of doctors and nurses in primary care (PC) to the implementation of interventions postulated by the Program of Preventive Activities and Health Promotion - PAPPS- target consumers patients alcohol (screening and temperance) advice.

Design: Observational descriptive, transversal.

Location: Multicenter. Health Centers of the National Health System in Spain.

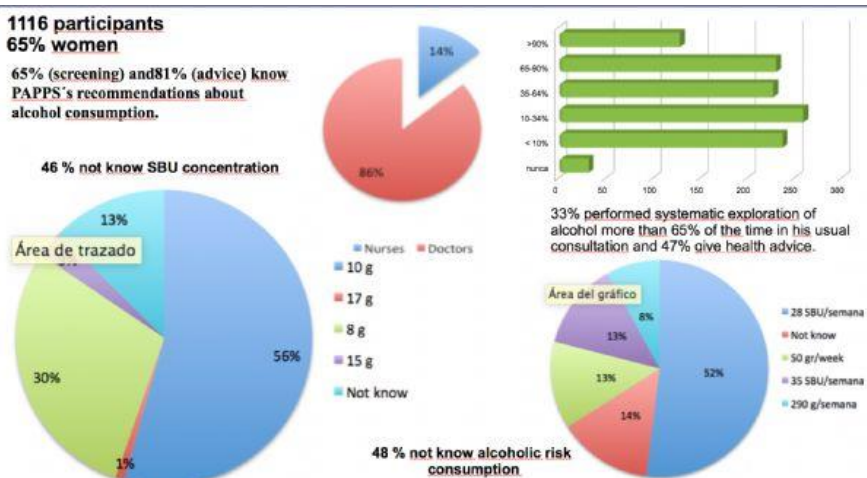

METHODS: Population: doctors and nurses PC. For an alpha error of 5% and an accuracy of 3% and a rate of 50%, would be recruited for the study to 1058 professionals. They were invited to engage all partners and professionals semFYC a sample selected through stratified sampling by autonomous communities and type of health facility. Once established their intention to participate, they completed an online survey. Variables: socio-labor, knowledge and practices on the approach in patients taking alcohol. Descriptive and inferential statistics (P <0.05 bivariate and multivariate analysis) will be made.

Applicability: Through the results of this study seeks to determine the knowledge, attitude and approach to PC professionals regarding this problem in our country, quite unknown aspects, so that thus may recommend to the Authorities Health intervention measures to increase the knowledge, awareness and implementation of preventive interventions temperance professionals PC.

Ethical and legal aspects: the protocol was approved by the Research Ethics Committee of Córdoba. Informed consent to the participants as well as the treatment of personal data will be required under the law of data protection

Keywords: Alcohol, Alcohol prevention, primary care

Bmi values in rural team family medicine

Sedina Bosankic, Dusanka Becirovic, Mirsada Crnogorcevic Pamukcic, Senada Hrcic

Department of family medicine, Health center Zivinice, Bosnia and Herzegovina

INTRODUCTION: The body mass index (BMI) is a measure of relative size based on the mass and height of an individual. BMI categories: less than 18.5 kg / m²-malnutrition; 18.5-24.9 kg / m² ideal nutritional status, 25-29.9 kg / m²-over-nourished and over 30 kg / m² obesity.

OBJECTIVE: To analyze the value of BMI in patients in rural family medicine team.

METHODS: Searched the 1471 medical records and was allocated 649 cards in which the recorded value of BMI. Data collected from medical records are entered in the form of data collection, which was created for this study. Recorded the following data: number of health records, age, sex, value of BMI, and the number of chronic diseases from which the patient is treated.

RESULTS: The research included 649 patients, 277 men (43%) and 372 women (57%), aged 18-94 years. The average age stood at 46.3 years. BMI values ranged from less than 18,5 to 47 kg / m². The average BMI was 28.3 kg / m². BMI below 18,5 kg / m² had 6 patients (0.9%), the value of 18-25 kg / m² had 192 (29.5%) patients, 25-30 kg / m² had 200 (31.1%) patients a BMI greater than 30 kg / m² had the 251 patients (38.5%). The majority of patients (347-53%) were healthy, with no chronic diseases. A chronic disease had 96 (15%) patients, two chronic disease had 83 (13%) patients and three or more chronic diseases had 123 (19%) patients.

CONCLUSION: In rural family medicine team is most obese patients, then those who are over-nourished, while the lowest number of malnourished patients. There is a positive correlation between the amount of BMI with one and then the number of chronic diseases on the other. Value BMI increases with age is the number of chronic diseases.

"Galactogogues and breastfeeding - what is the evidence?"

Maria Ana Sobral¹, Mario Cruz¹, Daniela Runa¹, Susana Medeiros¹, Inês Dias Ferreira², Sara Magalhães¹

¹Unidade de Saúde Familiar AlphaMouro, Rio de Mouro, Portugal

²Unidade de Saúde Familiar Venda Nova, Amadora, Portugal

INTRODUCTION: Often some mothers feel unable to extend the breastfeeding period according to their expectations. Whatever the reason, the use of lactation facilitators arises as an attempt to support the breastfeeding period extension by increasing milk production. Thus, the aim of this study is to determine the evidence of the effectiveness of galactogogues on the duration of breastfeeding and increase of milk production.

METHODS: We searched electronic databases for systematic reviews (SR), meta-analysis, randomized controlled trials (RCT), clinical trials, observational studies and guidelines published between January 2005 and January 2015 in English, Spanish and Portuguese. We searched MEDLINE, Clinical Queries, Cochrane Library, National Guideline Clearinghouse, CMA Infobase, NHS Evidence Search, DARE, Bandolier, Evidence-Based Medicine (BMJ) using MeSH terms "galactogogues" and "breast feeding". To rate the evidence we used the OCEBM Levels of Evidence.

RESULTS: We obtained 38 entries in our search. Of those, 34 were identified by reading the title. We selected 23 articles that met the inclusion criteria by reading the abstract. After reading these articles we excluded 19 articles, which did not answer our outcomes or address our objective. We obtained a final total of 4 articles: 3 SR and 1 RCT. None of the articles addressed breastfeeding duration, only evaluating the increase in milk production.

Several galactogogues were evaluated on the SR, but their conclusions were based on few trials with limited data.

CONCLUSION: There is no evidence of galactogogue effectiveness on the duration of breastfeeding. There is evidence of a modest increase in milk production on the short term in mothers of preterm infants who have insufficient breast milk production with the use of domperidone and some evidence that growth hormone might have a role in increasing milk production. However it is important to consider the potential risks of using these drugs.

Keywords: Breastfeeding; Galactogogues; Breastfeeding duration; Milk production

Results

Reference	Type of article	n	Population	Intervention	Comparison	Outcome	Results	Level of evidence
Timothy J Donovan The Cochrane Library 2012	SR with MA	59	Mothers of premature infants in neonatal unit with insufficient milk supply	Domperidone (10 mg, 3 times daily) since day 14	Placebo	Increase in milk volume	Modest increase in milk volume of 99,49ml daily	2
Mylove Mortel Journal of Human Lactation 2013	SR	587	Mothers with or without enough milk supply	5 herbs: Shatavari, torbangun, fenugreek, milk thistle, Japanese herbal mixture	Placebo	Increase in prolactinemia or milk volume	There is no evidence of an effect due to heterogeneity of the studies	1
McInnes RJ Maternal and Child Nutrition 2008	SR	148	Mothers of premature infants in neonatal unit	Domperidone Metoclopramide Oxytocin Growth hormone	Placebo	Increase in milk volume or breastfeeding duration	Domperidone* – increase milk volume Metoclopramide* * and Oxytocin spray*** – no effect, both studies were small Growth hormone**** – modest increase in milk volume	*2 **2 ***2 ****2
Knoppert DC Journal of human lactation 2013	RCT	15	Mothers of premature newborns	Domperidone 20 mg 3 times daily for 4 weeks, at week 5 twice daily and once daily for week 6	Domperidone 10 mg 3 times daily for 4 weeks. At week 5 twice daily and once daily for week 6	Increase in milk volume	20 mg instead of 10 mg was associated with clinical, but not statistically significant increase in milk production	3

Awareness of gestational diabetes mellitus among pregnant women in a health center in Turkey

Emel Kelestemur¹, Esengul Turkyilmaz², Irep Karatas Eray¹, Ayse Filiz Yavuz Avsar³

¹Department of Family Medicine, Ataturk Training and Research Hospital, Bilkent, Ankara, Turkey

²Department of Obstetrics and Gynecology, Ataturk Trainig and Research Hospital, Bilkent, Ankara, Turkey

³Department of Obstetrics and Gynecology, Yildirim Beyazit University, Bilkent, Ankara, Turkey

Background and AIM: Gestational diabetes mellitus (GDM) is defined as glucose intolerance that is first diagnosed during pregnancy. GDM is a kind of diabetes with a high risk of maternal and fetal morbidity. For the decrease in fetal morbidity and prevention of Type 2 diabetes mellitus (DM) development in mother, a 1-h 50-g oral glucose tolerance test (50g OGTT) is strongly recommended for 24-28 weeks of gestation according to guideline of the society of endocrinology and metabolism of Turkey (TEMED). Lately, it has been observed that the number of pregnancies, who do not attend OGTT, is continuously increasing. This study was done to understand the reasons of that increase and measure the knowledge of pregnancies about OGTT. METHOD: This study is consisted of a questionnaire, which is designed to measure the knowledge of pregnancies about the OGTT with 14 questions. It was conducted on pregnancies admitted to pregnant clinic during the months of February-2015 and April-2015. RESULTS: Three hundred and forty-two pregnant women participated in the study. Mean age of the women was 27.7 years and mean week of gestation was 19.3. Overall, 52.1% women did not want to attend OGTT and 63.2% of that believed that OGTT was harmful for both mother and fetus. 48.7% of the women, who believed that OGTT was harmful, acquired this knowledge from the television/radio. CONCLUSION: Person-oriented preventive medicine is one of the major responsibilities of family doctors. Advising and education are indispensable for periodic health examination. However, because of the wrong and non-evidence based information on the media, some of the screening test such as OGTT, can be refused. The decrease in the incidence and prevalence of disease having a high risk of morbidity including GDM can be achieved only with correct and evidenced based advising and education given by family doctors.

Assessing how well Diabetes is controlled in General Practice

Madalina Daniela Graure, Alexandru Claudiu Coman, Elena Martínez García, Jose Pedro Olivo Ros, Victor Arroyo Moreno, Juana Flores Torrecillas, Rosa María Requena Ferrer
Cartagena Casco Antiguo Health Center, Cartagena, Murcia, Spain

• Background & Aim

A maintained chronic hyperglycemia in diabetics results in micro and macrovascular long term complications increasing morbidity and mortality. Our main objective is to determine if the diabetics from our health centre present an adequate metabolic control.

Specific OBJECTIVES:

- Determine the prevalence of DM I and II
- Determine the HbA1c and the prevalence of cardiovascular risk factors: BMI, abdominal perimeter (AP), high blood pressure (HBP), hypercholesterolemia (HCL), hypertriglyceridemia (HTG), smoking, renal function
- Determine the prevalence of metabolic syndrome and high cardiovascular risk (SCORE)
- Determine which DM treatment is best related to good metabolic control

• Method

Design: cross-sectional study

Inclusion criteria:

- ≥18 years
- DM I or II

Exclusion criteria:

- Disabled patients
- Pregnant women
- Who do not want to participate

Sample size: 302 (95% confidence level, 5% precision rate, estimated loss 5%).

Sampling: simple random

Once selected the patients, they are called to come to the center on Fridays for data collecting.

Variables: gender, age, type of DM, HbA1c, BMI, HBP, HCL, HTG, smoking, metabolic syndrome, if they present HbA1c annual control, SCORE, DM treatment, renal function (glomerular filtration rate, creatinine, microalbuminuria).

Those who present an inadequate control are scheduled for treatment adjustment.

Data will be processed in SPSS-18.0.

• Results

Our study will finish in May of 2015. The data collected and processed until this date indicates that our patients could be better controlled and that most of them present metabolic syndrome. Overweight and obesity is a major risk factor present in more than 50% of the patients. Renal function should be better investigated.

• Conclusions

Our study will offer real information about the control of DM and if enough attention is given to other cardiovascular risk factors which increase global mortality. Our results will help us implement new follow-up strategies for a better control.

Depression Levels And Affecting Factors In Health Care Workers

Kenan Taştan¹, Abdulkadir Kaya¹, Beytullah Ismet Demirhan¹, Suat Sincan²

¹Ataturk University Medical Faculty Department of Family Medicine

²Atatürk University Student Health Center

Introduction and OBJECTIVES: Depression is important health problem, because of the prevalence and causes loss of ability. Lifetime prevalence ranged 10%-20%. Depression has presented at the beginning the most common diagnosis among all disorders in patients who presented to primary health care. In many studies, the role of working environment was determined in mental health disorders on workers. In this study, we aimed to discuss the factors that affect depression levels on health professionals.

METHOD: 337 people were taken randomly, admitted to policlinic of workplace health service in Atatürk University. Beck Depression Screening Scale Turkish translation for primary care were applied to patients. Results were analyzed with SPSS. Fisher's exact test and Mann-Whitney test were used. P value <0.05 was accepted for significant.

RESULTS: The average age of people in the study was 34.6±10.2. 56.9% of respondents (n=192) were female, 43.1% (n=145) consisted of men. The average of the scores obtained from the Beck Depression Screening Scale of the patients were 1.7±2.2. In this study, 11.3% (n=38) people 5 and above, 1.5% (n=5), people also took scores of 10 and above. 9.8% of participants (n=33) had received a diagnosis of depression before. The average of the depression scores of these individuals were significantly higher than those without a previous diagnosis (P<0.001). The situation of participants receive a diagnosis of depression before between marital status was not a significant relationship (p=0.13).

Conclusion and DISCUSSION: Depression ratio of health workers in a study in Brazil found 16%. Our study seems to be lower than that rate. Depression rate in people who participated in the study were close to the lower limit of depression rate in our country. Such as working in a hospital and in occupations that have night duty, there is a need for wider participated studies related to mental disorders.

Screening for abdominal aortic aneurysm - an evidence-based review

Vítor Portela Cardoso¹, Paula Mendes²

¹USF Gualtar, ACES Cávado I, Braga, Portugal

²USF Maxisaúde, ACES Cávado I, Braga, Portugal

Background and AIM: An Abdominal Aortic Aneurysm (AAA) is defined when the diameter of the aorta is greater than 3 cm. The estimated prevalence is 4-9% in men and 1% in women. Although usually asymptomatic, the rupture of an AAA is associated with a mortality rate of 80%. If detected early, the mortality rate of elective surgery for AAA is 5%. Our aim was to review the evidence of mortality and adverse effects of screening for AAA in asymptomatic adults.

METHODS: We conducted a research for meta-analyzes (MA), systematic reviews (SR), randomized clinical trials (RCT) and clinical practice guidelines (CPG), in the data sources National Guideline Clearinghouse, Guidelines Finder, Canadian Medical Association Practice Guidelines, Cochrane, DARE, Bandolier, Medline and Index of Portuguese Medical Journals, published between 01/01/2003 and 03/23/2013 in Portuguese, Spanish, English and French languages, using the MeSH terms abdominal aortic aneurysm and mass screening. We used the Oxford Centre for Evidence-Based Medicine scale for assessment of levels of evidence (LE).

RESULTS: Of 337 articles obtained, 10 met the inclusion criteria (2 MA, 1 SR and 7 CPG). The SR and the MA selected showed that screening for AAA significantly decreased mortality in men aged between 65-75 years old, but not in women. A reduction in all-cause mortality was observed in one MA, which estimated a number needed

to screen of 156. This is lower than the number needed to screen in current cancer screening programs. Screening doubled the number of elective surgeries and decreased the number of emergency surgeries for ruptured AAA by half.

CONCLUSIONS: Consistent, good quality evidence demonstrated a reduction in mortality from AAA by screening asymptomatic men aged ≥ 65 years (LE1). The treatment of AAA is associated with significant risk of death and surgical complications, which may be acceptable in individuals at high risk.

Keywords: abdominal aortic aneurysm, mass screening, mortality, side effects.

Substance consumption in Paredes teenagers and young adults

Carlos Franclim Moreira Silva¹, Paulo Alexandre Azevedo Pereira Santos², Paula Alexandra Rocha³

¹USF S. João do Porto

²Faculdade de Medicina da Universidade do Porto

³CIES-IUL e ICS- Universidade do Minho

BACKGROUND: Habits, lifestyles and potential risk behaviors are mainly acquired during adolescence. Paredes, a county in the north of Portugal, is on top 10 of the youngest municipality, with people between 14 and 24 years of age counting for 14,1% of total inhabitants.

AIM: To characterize substance use habits of young inhabitants of Paredes.

METHODS: We conducted a cross-sectional study with population basis of young people aged 14 to 24, living in Paredes. An auto-administrated questionnaire was distributed using the random route method to a stratified cluster sample of 746, from May/2013 to September/2014. We accepted an alpha error of 0,05.

RESULTS: The majority of young people have tried alcohol (81,9%), specially males ($p=0,017$), with the median of 15 years old for the first time. Tobacco was used by 54,5%, mainly by males ($p=0,001$). The median of the first time for tobacco was 15 years old. Cannabis was experienced by 13,9%, most in males ($p<0,001$) with the median age for the first time at 16 years old. Dropping out of school system is significantly associated to high prevalence of harmful habits.

CONCLUSIONS: The consumption of harmful substances is a major health problem in this population, mainly in the male gender. The school appears to have a protective effect in teenagers and young adults

Keywords: adolescence, substance use, tobacco

Is the prevalence of smoking in Federation of Bosnia and Herzegovina decreased in 2015?

Olivera Batic Mujanovic¹, Azijada Beganlic¹, Larisa Gavran², Edita Cerni Obrdalj³, Amra Zalihic³

¹Family Medicine Teaching Centre of Health Centre Tuzla; Department of Family Medicine, Medical Faculty of Tuzla University, Tuzla, Bosnia and Herzegovina

²Family Medicine Teaching Centre of Health Centre Zenica; Department of Health Care in Community, Health Faculty of Zenica University, Zenica, Bosnia and Herzegovina

³Family Medicine Teaching Centre of Health Centre Mostar; Department of Family Medicine, Medical Faculty of Mostar University, Mostar, Bosnia and Herzegovina

Background & AIM: Cigarette smoking is the largest preventable risk factor for morbidity and mortality in developed countries. We compared prevalence of smoking in people attended primary care centres from three cantons in Federation of Bosnia and Herzegovina 2015 and 2012.

METHODS: Study included people attended 16 primary care centres 2015 and 21 primary care centres 2012 from three cantons: Tuzla Canton, Unsko-Sanski and Posavski Canton. Every family medicine team, involved in the Program of Additional Training in Family Medicine, completed questionnaire for 100 patients about their smoking status and readiness to quit smoking. Data collections were performed between February-March 2012 and 2015.

RESULTS: Study included 3700 participants (aged 10-88 years): 1761 (47.59%) men and 1939 (52.41%) women. Prevalence of smoking 2015 is significantly lower than 2012 (40.06% vs. 47.71%; $p<0.0001$). Significantly more men than women are still smokers (50.82% vs. 38.58; $p<0.0001$). Number of ex smokers remained approximately the same 2015 and 2012 (17% vs. 17.1%; $p=0.9$). Significantly more men than women are still ex smokers (21.98% vs. 12.62%; $p<0.0001$) 2015 and 2012. Significantly more women than men have never smoked (61.95% vs. 22.95%; $p<0.0001$) 2015 and 2012. Significantly lower percentage of smokers don't think to quit smoking 2015 compared to 2012 (48.67% vs. 53.6%; $p=0.05$), while percentage of smokers who think to quit in the next six months is approximately the same 2015 and 2012 (38.53% vs. 37.5%; $p=0.68$). Significantly higher percentage of smokers are ready to quit smoking immediately 2015 compared to 2012 (12.79% vs. 8.88%; $p=0.01$).

CONCLUSION: Results of this study shows that the prevalence of smoking in Federation of Bosnia and Herzegovina

is still very high. It suggests more effective interventions of primary care teams to identify people who smoke and offer them comprehensive advice and appropriate treatment to quit smoking.

³Adana Numune Training and Research Hospital, Department of Psychiatry, Adana/Turkey

⁴Baskent University Medical Faculty, Department of Family Medicine, Ankara/Turkey

BACKGROUND: To investigate social support status, sexual life satisfaction, anxiety and depression risk and quality of life of the breast cancer patients who were being followed up and treated at Medical Oncology Clinic of Adana Numune Research and Training Hospital.

MATERIAL-METHOD: This is a cross-sectional study conducted with 107 women who were admitted between 1 August 2014 and 31 October 2014. Demographic characteristics, breast cancer risk factors, disease process of the patients were questioned. Arizona Sexual Experience Scale, Multidimensional Perceived Social Support Scale, Hospital Anxiety and Depression Scale, World Health Organization Quality of Life Scale Short Form Turkish version (WHOQOL-BREF TR) were applied to the patients. Two independent sample t-test, One Way Anova, Chi-square tests were used for statistical analysis.

RESULTS: Mean age of the patients was 49.5±10.4 years (range 26 to 74 year). While 43.9% of the patients were illiterate, 42.1% were graduates of elementary-intermediate school, 14% were graduates of high school-university. Of the patients, 87.9% were in low income group, 12.1% were in moderate-high income group, 68.2% (n=73) of the patients were married. Anxiety risk was found in 29.0% (n=31) and depression risk was found in 58.9% (n=63) of the patients. Social support and quality of life were seen to be poorer in patients with high anxiety risk (p=0.010, p=0.0001). Satisfaction from sexual life (p=0.0001), social support (p=0.0001) and quality of life (p=0.0001) were found poorer in the patients whose depression risk was high.

CONCLUSION: The patients with breast cancer should not be only biologically treated but also psychological and social support should be provided and quality of life should be improved. High ratios of anxiety and depression require multidisciplinary approach. These measures which are taken during follow up and treatment would improve quality of life.

Assessment of Health Care Utilization in Different Sociocultural Groups Living in Adana Province

Aslı Korur¹, Nafiz Bozdemir², Esra Saatçi², Çiğdem Gereklioğlu¹, Süheyl Asma¹

¹Başkent University, Department of Family Medicine, Adana, Türkiye

²Çukurova University, Department of Family Medicine, Adana, Türkiye

Background&AIM: The aim of this study was to assess the utilization of health care settings in different sociocultural groups in the city center of Adana, the relationship between sociodemographic parameters and utilization of health care systems and to show the ecology of medical care.

METHOD: We enrolled 685 person living in three different sociocultural regions (high, moderate, poor) in Adana province. The study was conducted from 1 May 2009 to 15 June 2009. Sociodemographic data collection questionnaire, health attitude behavior assessment questionnaire and short form-12 (SF-12) short health scale were completed face-to-face. Data was installed and analyzed with statistical package programs.

RESULTS: Of 685 individuals, 504 (73.6%) were women, 181 (26.4%) were men, the mean age was 36.68±13.89 years (range:18-83). Of individuals, 273 (39.9%) were primary school graduates, 520 (75.9%) were married, 479 (69.9%) had a history of moving to Adana, 577 (84.2%) had social insurance, 368 (53.7%) assessed their socioeconomic status as 'moderate'. There was significant relationship between the educational status, social insurance status, socioeconomic status and marital status and MCS-12, a subscale of SF-12. (p<0.05) The most preferred health care setting was the secondary health care for both acute and chronic health problems. There was a significant relationship between the preferred health care settings and sociodemographic parameters (gender, educational status, age, social insurance, socioeconomic status) (p<0.01) During the last one month, 540 participants (78.8%) reported at least one health problem, 433 (38%) had self-care, 323 (28.4%) admitted to a secondary health care unit, 309 (27.1%) admitted to a primary health care unit and 2 (0.5%) were hospitalized. **CONCLUSIONS:** The utilization of health care settings is influenced by sociodemographic parameters. The most

preferred health care setting is the secondary health care. Primary care should be improved and strengthened.

Exercise and Diabetes: A transversal study in a Portuguese Health Center

Sara Neves Costa, Sara Madeira, Joana Gabriel, Carina Vargas

USF Mactamã, ACES Sintra, Portugal

Background and AIM: The treatment of Type 2 Diabetes Mellitus (T2DM) is based on 3 bases, diet, physical exercise (PE) and pharmacotherapy. The importance of PE on T2DM justifies its recommendation by several scientific institutions.

The family physician (FP) has a fundamental role promoting behaviour changes, especially on chronic diseases. The aim of the study was characterize the relevance and knowledge of T2DM patients concerning the role of PE in the management of their disease.

METHODS: We conducted an observational, transversal, descriptive and analytical study, between April and September 2014. The population included the adult patients with a diagnostic of T2DM followed in the Unidade de Saúde Familiar Mactamã.

The data was collected by a questionnaire (especially design for this study) that included the evaluation of the Physical Activity Index.

RESULTS: 7% of the 98 patients were classified as active and 42% reported doing PE exercise as part of their T2DM treatment. The risk of being inactive increases with age (OR[CI95%]:1,07[1,01-1,13]), it's 3 times higher in women (OR[CI95%]:2,95[1,07-8,08) and increases with the Body Mass Index (OR[CI95%]:1,13[1,00-1,28]).

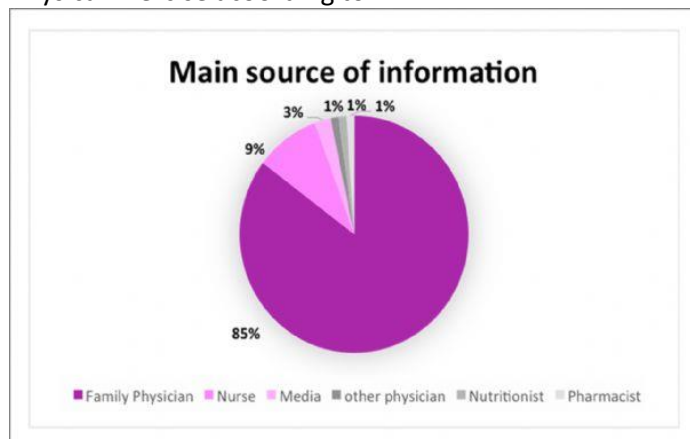

The majority of patient knew how to identify the PE recommendations and the main source of information was the FP. The patients said they were advised to practice PE in almost all appointments and considered being satisfied with the received information.

CONCLUSION: The prevalence of PE reported is equivalent to other national studies. The fact that the patients know the recommendations and are satisfied with the medical counselling, does not determine the practice of PE in the majority of this sample.

It would be important to evaluate, in future studies, the patient's motivations and limitations to practice PE in order to improve the FP interventions and increase the PE practice in T2DM patients.

Online structured education with email facilitation for people with type 2 diabetes: pilot study

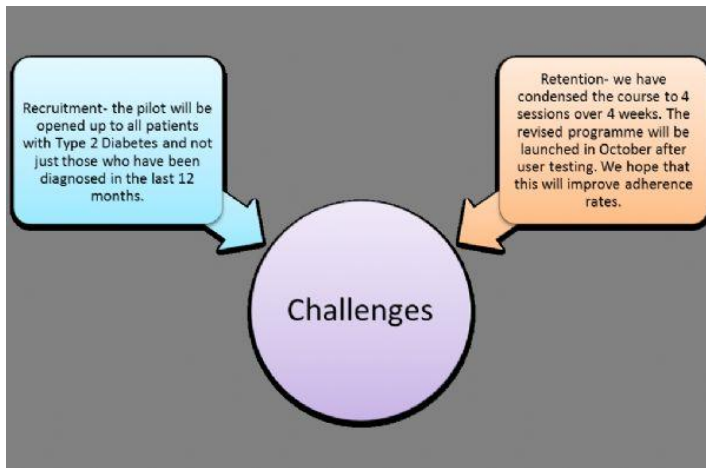

Shoba Poduval

Department of Primary Care and Population Health, University College London

Type 2 Diabetes Mellitus (T2DM) is one of the most prevalent non-communicable diseases in the world affecting 3.8 million people in the UK alone. Annually £9 billion is spent on diabetes in the UK. Many of these costs are due to preventable complications. Data suggests that improved self-management can reduce the risk of complications fourfold. Uptake of self-management education programmes has been low, and one possible reason for this is that almost all are delivered through group-based sessions. Our research seeks to provide a more effective way of delivering self-management education to people with T2DM. I am working with an established multidisciplinary team at UCL who have developed an online structured education programme called "HeLP-Diabetes: Starting Out". A pilot study is needed to determine its acceptability and effectiveness, in order to optimize the programme and inform the design of a feasibility trial. We have designed a single arm mixed methods study to determine follow-up rates; uptake and adherence; data quality; changes in self-reported knowledge, self-efficacy, health behaviours, and diabetes-related distress; and resources required. The results of this research will allow us to apply for competitive funding for a feasibility study and subsequently for a definitive Phase 3 RCT. We will be contributing towards the body of knowledge on computerised self-management programmes for long-term conditions. The intervention has the potential to provide easily accessible self-management education to a large number of patients in a cost-effective way.

Overview of sessions

There are 8 sessions and they are listed below.

At the beginning of the course, we ask you to complete a questionnaire. This will tell us what you know already, and which areas you need most help with.

At the end of the course, we'll ask you to do the questions again.

We hope this will show you how much you've learnt, and encourage you to keep on doing things that you've learnt make you feel happier and healthier.

If you want to find out more details about the 8 sessions, you can look at the [learning goals](#).

- Session 1: Getting started
- Session 2: Self-management
- Session 3: Improving my health and well-being
- Session 4: Taking control of my diabetes
- Session 5: Medication and lifestyle
- Session 6: Reducing my risks
- Session 7: Working with my health care team
- Session 8: Celebrating success and planning for the future

Please click on the **Next** arrow to find out about email support available to you as part of this programme.

Part 3 - Reducing the risks of heart attacks and stroke

Relationship Between Premature ventricular complexes and Neutrophil–Lymphocyte Ratio in asymptomatic healthy young men

Erkan Kibrisli¹, Sinan Iscen², Ahmet Yilmaz¹, Salim Ozenc³, Adem Parlak⁴, Duran Tok⁴

¹Family Physician, Dicle University Medicine Faculty Departments of Family Medicine, Diyarbakir, Turkey

²Cardiologist, Diyarbakir Military Hospital, Yenişehir, Diyarbakir, Turkey

³Family Physician, Diyarbakir Military Hospital, Yenişehir, Diyarbakir, Turkey

⁴Family Physician, Presidential Guard Regiment, Ankara, Turkey

BACKGROUND: Premature ventricular complexes (PVC) are a relatively common electrocardiographic abnormality presenting in individuals without overt cardiovascular disease. There is no clear mortality benefit from VPB suppression in asymptomatic patients. In addition, It has been showed that evidence for structural heart disease consistent with non-ischemic scarring possibly due to inflammation in patients with premature ventricular beats. This situation suggests that the mechanisms by which VPBs can be also generated with include clinical and subclinical inflammation. The neutrophil–lymphocyte ratio (NLR) is an easy, cheap, noninvasive, and universally available laboratory marker used to evaluate clinical and subclinical systemic inflammation. We investigated the NLR in asymptomatic healthy young men with PVC (structural heart disease excluded with cardiac magnetic resonance imaging) compared with controls. The study group consisted of 21 asymptomatic healthy young men with PVC (mean age 22.7 ± 2.0 years). Insead of Lown's grading of VPBs, we considered as endpoints > 153 PVC over 24 h (in Holter Electrocardiogram). The control group consisted of 922 male (mean age $22.6 + 3.1$ years). Hematologic indices were measured within 30 minutes of collecting the blood samples in tubes containing dipotassium EDTA. There were no significant differences between the 2 groups with respect to age, gender, body mass index, smoking, creatinine, total cholesterol, triglyceride, LDL-C, HDL-C, hemoglobin levels, white blood cell count, and red cell distribution width. The NLR was significantly higher among the men with PVC than that of the control group (2.7 ± 0.7 vs 1.5 ± 0.4 , respectively; $P < .001$) We found that the NLR is significantly elevated in asymptomatic healthy young men with PVC compared with control participants. The increased NLR values might indicate subclinical and clinical inflammation in asymptomatic healthy young men with PVC, and we must consider that there can also be inflammation about the mechanisms of VPBs in humans.

The Impact of Smoking Habit on HbA1c Level

Izzet Fidancı, Oğuz Tekin, İsmail Arslan, Şükrü Ümit Eren, Gökhan Dinçer, Özlem Kızıldaş
Department of Family Medicine, Ankara Training and Research Hospital, Ankara, Turkey

OBJECTIVE: In this study, we aimed to assess the impact of smoking habit on glycated hemoglobin, HbA1c.

MATERIAL-METHOD: We applied a questionnaire asking demographics and smoking status to 204 patients admitted Ankara Training and Research Hospital, Family Medicine Outpatient Clinics and got a HbA1c level. Body mass index was calculated for all patients. Fagerström Nicotine Dependence Test was applied to smokers.

RESULTS: Of 204 patients, 101 were male (49.5%) and 103 were female (50.5%). The study population consisted of 69 (33.8%) previous smokers, 63 (30.9%) smokers, and 72 (35.3%) never smoked patients. Mean age of patients was; 34,84(±12.53) years in previous smokers, 35.83(±14.70) years in smokers, and 41,75(±13.84) years in patients who never smoked. HbA1c level was significantly higher in males than females ($p<0.05$). In the assessment of age-HbA1c relationship, HbA1c levels was positively correlated with age ($p<0.05$). HbA1c levels was significantly higher in smokers and previous smokers than patients who never smoked ($p<0.001$).

CONCLUSION: According to our results, smoking habit increases the HbA1c level and is an important changeable risk factor, especially for patients with diabetes mellitus. We should promote to cessation of smoking in smoker patients to improve regulation of blood glucose level and prevent diabetes mellitus.

Keywords: Smoking, HbA1c, Diabetes Mellitus

Table-1. According to the average of the variable Smoking Habits.

Our one month experience of diagnostic variations and demographics of the cases that admitted to family medicine outpatient clinic

Nur Şimşek Yurt, Feyza Nur Topçu Yenerçağ, Mahcube Çubukçu

Department of Family Medicine, Samsun Education and Research Hospital, Samsun, Turkey

AIM

To determine the diagnostic variations and demographics of the cases that admitted Samsun Education and Research Hospital, Family Medicine Outpatient Clinic and to plan a more qualified health service practice intended for our target group.

MATERIAL and METHOD

Study was conducted by the data of the patients over sixteen years who admitted to Family Medicine Outpatient Clinic in Samsun Education and Research Hospital in between 25.11.2010 and 25.12.2010 that obtained by hospital electronic registration system with file screening method. The data was evaluated retrospectively.

RESULTS

Of the 104 patients admitted to our Family Medicine Outpatient Clinic in between 25.11.2010 and 25.12.2010, 51 (%49.0) were women and 53 (%51.0) were men. Mean age was 48.6 in women and 46.1 in men. When the diagnoses were examined, the most common reasons for admission to our clinic were general medical examination (%27.9), hyperlipidemia (%11.6), hypertension (%10.6), anxiety (%9.6), dyspepsia (%8.7), stomachache (%6.8), anemia (%4.8), urinary tract infection (%3.8), diabetes mellitus (%3.8), myalgia (%3.8), lumbalgia (%2.8), angina pectoris (%1.9), chronic sinusitis (%0.97), epistaxis (%0.97), hypothyroid (%0.97), tinnitus (%0.97). It's detected that 57 of the cases (%54.8) were not prescribed and 47 of them (%45.2) were prescribed.

CONCLUSIONS

As admissions to Family Medicine Outpatient Clinic were evaluated, the number of the women and men was found very close to equal and the most of our cases were in the middle age group. Chronic diseases like hypertension and diabetes were seen less often than their prevalences in Turkey. Because of the fact that our Family Medicine Outpatient Clinic is also serving as a periodic health examination institution for the adult people who doesn't suffer from any diseases, admissions for the general medical examination were the majority. Trainings may be planned to improve the quality of the service for our most common diagnoses in outpatient clinic.

Assessment of the nutritional status of the patients who are followed by home care unit

Feyza Nur Topçu Yenerçağ, Nur Şimşek Yurt, Mahcube Çubukçu

Department of Family Medicine, Samsun Education and Research Hospital, Samsun, Turkey

OBJECTIVE: We aimed assessment of socio-demographical and medical properties of the patients using nutritional products, who are followed by Samsun Education and Research Hospital Home Care Unit.

METHODS: Our study have been performed by analyzing the data of patients older than sixteen years old who are followed by Samsun Education and Research Hospital Home Care Unit between January 2014 to April 2015. This study is retrospective and descriptive type of study.

RESULTS: We included 71 patients to the study, which have malnutrition or under the risk of malnutrition. We excluded the patients who have died before the study ended. 52 (73,2%) of the patients were women, 19 (26,8%) were men, and the mean age of the study was 77,5. 62 (87,3%) of the patients were bedridden, 9 (12,7%) were nearly bedridden. 18 (25,3%) of the participants had decubitus ulcers. Patients who were included to our study, had been using enteral nutrition for the mean of 11 months. 52 (73,2%) of the patients were taking their nutrition orally, 13(18,3%) with PEG, and 6(8,5%) of them were with nasogastric catheter. 50,7% of the participants have had Alzheimer disease, 35,2% have had some kind of serebrovascular disease, 7% have had chronic renal failure, 4,2% have had epilepsy, and 2,8% have had demans. The mostly seen comorbidity among the patients was hypertension with the number of 28(%39,4) people. Diabetes Mellitus was the following one with the number of 15(%21,1).

CONCLUSION: Nutrition is the most important changeable factor for well being of the patients. Particularly for the home care patients to improve the well being, and the state of the disease, nutrition should be performed in adequately by proper ways. To come to a conclusion; it is very important to find out nutritional status of home care patients and curing the malnutrition by appropriate ways.

Media Effects on Statin Treatment and Determination of Reaching the Target LDL Ratio

Gökhan Dincer¹, Zeynep Sayın Dincer², Yakup Alsancak³, Enes Gümüüş¹, Nuri Şengüleroğlu¹, Aybüke Demir Alsancak², İsmail Arslan¹, Oğuz Tekin¹

¹Department of Family Medicine, Ankara Training and Research Hospital, Ankara, Turkey

²Department of Family Medicine, Ankara Numune Training and Research Hospital, Ankara, Turkey

³Department of Cardiology, Ankara Atatürk Training and Research Hospital, Ankara, Turkey

Background-AIM: As a result of extensive researches, patients who clinical requirements although the unquestionable benefits of treatment statin, recently, there is many discussion about the use of statins on media in Turkey.

It was aimed to report media effects on compliance with medication on statin therapy and determination of reaching the target LDL(Low density lipoprotein).

METHOD: The descriptive and observational research was conducted between October 2014- February 2015.

Data were collected from office of family medicine. The study population comprised patients who use statin at time of study, newly diagnosed dyslipidemia or discontinued statin therapy. Demographic-clinical characteristics, views about use of statins and health related behaviours of participants were collected from a questionnaires.

RESULTS: 58 male and 113 female patients(n=171) were included to study(mean age:62.6 years). 130 patients took statin before and 42.6 % of them were still on treatment. 36.6 % of these patients had target LDL values and the average duration of treatment was 6.6 years. Compliance with medication was not associated with sociodemographics such as age, sex, education level and financial income. Patients who discontinued statin therapy (n=70) were because of media effects in 52.9% and other physician's decision in 34.3%. Patients who discontinued or not previously initiated therapy were 111 people. 28.8% of them refused to use statins(93.8% of them media effects).

CONCLUSIONS: Although the evidences during last twenty years showed benefits of reduced LDL, it is still far for optimized target levels, compliance with medication and initiation of therapy all over the world. Results are similar in our study. Besides appropriate treatment, It is important to provide patient compliance in family medicine

practice. These findings show that media effects on patient attitude towards statins and treatment compliance. It is clear to need that family physicians should evaluate the compliance and inform patients openly.

Study of Informational Awareness of Patients before Elective Surgery

Audrone Fabijanskiene¹, Ernesta Statkuvienė², Simona Vainoriene², Ligita Siauryte Skipariene², Lina Jaruseviciene², Violeta Simatoniene³

¹Primary care center "Saulene", Joniskis

²Department of Family Medicine, Lithuanian University of Health Sciences

³Department of Physics, Mathematics and Biophysics, Lithuanian University of Health Sciences

Patient informing before elective surgery strengthens patients motivation to take an active role in treatment process, increases his satisfaction with health care services and enhanced readiness of people, who belong to patient's social environment to help actively the patient during recovery time.

The objective of the study - to explore patients' informational awareness about elective surgery procedure and to identify factors related to better patients' preoperative awareness.

Methodology. The survey of patients' hospitalized to the Hospital of Lithuanian University of Health Sciences and Siauliai Republican Hospital. The study participants: 191 patients from the surgical units, 189 - from the ophthalmology units, 199 – from orthopedics and traumatology units. The instrument: 102-item questionnaire that consisted from sociodemographic questions, questions concerning the patients' anxiety before elective surgery, patients' informational awareness and their expectations for preoperative counseling.

Results. 37.5% of men and 62.5% of women participated in this cross-sectional survey. The highest informational awareness (more than 80% of patients) was found on the issues related to the admission to the hospital and current health status. More than 50% of patients were aware of the aspects related to the future surgery. Less than 50% of study participants knew about the potential consequences of the surgery and the possibilities for social assistance. Younger age, male gender, lacks of previous experience of hospitalisation and surgeries, the preoperative community nurse counselling was related to better informational awareness of the patients.

Conclusion. Aiming to improve informational awareness of patients before elective surgery special attention should be paid to the involvement of community nurses in this process, issues related to the potential consequences of the surgery, wound care options, social assistance opportunities should also be included in the agenda of preoperative counseling.

Keywords: elective surgery, preoperative patient counseling, community nurse

That we attend to complications of diabetes in service of urgencies?

Juan Carlos Montalva Barra, Pedro Garcia Bermejo, M Teresa Magdalena Carreres, Luis Manclús Montoya, Oscar Martinez Ferris, M Teresa Benavent

Hospital de la Ribera-Alzira

The prevalence of complications dress in service of urgencies it is very variable.

We Realize a descriptively observational study, retrospectively and transversely from patients seen by diabetic complication sharp During the year 2014, Obtaining information from system SIAS and analyzes estadístico by Means of SPSS version 22.0 urgencies Attended Of 191 patients in 12 HAD more of 1 complication. 51.83 % of men with middle ages women 61.57 years and 39.79 % rest hyperglycemia was not cetósics, hypoglycemias 23.03 % (10 % serious Considered), 10.47 % and 4.72 % metabolic ketoacidosis of diabetic début

Addition There Were Studied in the co - morbidity Associated With sharp pictures separating macro - vascular disease (coronary, cerebrovascular or peripheral artery) and microvascular (retinopathy, nephropathy or neuropathy). Were Observed 28.79 % of macrovascular disease and 13.61 % Been Diagnosed of some microvascular alteration. 53.92 % of patients was hypertense acquaintances and in 29.31 % dislipemics needed treatment after adjustment of urgency 50.78 % c of the patients of Whom Were 35 5 Adjustments of insulin destination of the valued patients was: 40.83 % domiciliary discharge, 20.41 % I join short unit stay or medicine he hospitalizes and only 7.32 % needed reference to external consultation of endocrinology

Conclusion

The discharge prevalence of Complications for diabetic decompensation in our hospital Supposes 3.8 % of the hospitable income. The Control of Complications and comorbidities can improve increase in the short and the long term monitoring of the above Mentioned Complications and improve increase naturally the history of the diabetes of our patients.

Respiratory Function Assessment in Cork Industry Workers and its Relationship with the Spirometry Standard compatible with Suberosis

Pedro Ribeiro Oliveira¹, Patrícia Cunha¹, Diana Brigas¹, Rosa Neves¹, Ricardo Oliveira²

¹USF Fiães, ACeS Feira/Arouca, Fiães, Portugal

²USF Escariz, ACeS Feira/Arouca, Escariz, Portugal

Suberosis is a pulmonary interstice disease caused by a repeated exposure to cork dust and mold. It is the most prevalent pulmonary interstice disease in the north of Portugal where cork industry is placed. The studies of the pulmonary function in suberosis patients usually reveal a restrictive pattern.

The main objectives of this study are to verify and quantify if time and type of exposure to cork dust and mold increase the risk of developing a restrictive spirometric pattern (compatible with suberosis). The type of exposure (severity) was defined from the job/working place of each worker.

For this purpose, a sample of 59 workers exposed to cork's dust and mold and a control group of 61 subjects not exposed have been selected. Spirometric tests have been performed in both groups.

The results show that the time and type of exposure to cork dust and mold are risk factors for the development of a restrictive pattern in exposed individuals. A light exposure leads to a risk of developing a restrictive pattern five times higher than the unexposed; a moderate exposure increases the risk nine times and severe exposure increases the risk fifteen times. For short-term exposure (less than 15 years) statistically significant results have not been obtained. The medium-term exposure (between 15 and 30 years) leads to a relative risk of developing a restrictive spirometric pattern nine times higher when compared with the control group, while the long-term exposure increases the same risk eleven times.

Keywords: Cork, Dust, Spirometry, Risk

Type of exposure

This figure shows the relationship between the Type of Exposure and the Spirometric Pattern

Years of Exposure

This figure shows the relationship between the years of exposure and the spirometric pattern

Table: Type of exposure/ spirometric pattern

	Type of Exposure				Total
	Light	Medium	High	Non-exposed	
Restrictive Pattern	11 (39.3%)	12 (54.5%)	6 (66.7%)	7 (11.5%)	36 (30%)
Normal Pattern	17 (60.7%)	10 (45.5%)	3 (33.3%)	54 (88.5%)	84 (70%)

⁸Ladik Merkez Primary Health Care Centers

⁹Vezirköprü Cumhuriyet Primary Health Care Centers

AIM

This study has been done for determining of the rates and preferences on birth planning method which applied by womens in the 15-49 age range who are living in Samsun.

MATERIAL and METHOD

Between 01.01.2014 and 31.12.2014, Samsun province was carried out by Primary Health Care Centers 8th, in the 15-49 age range registered in 4221 made woman screening method using the data file saved in the talks. All admitted patients aged 15-49 years were included in the study. Data were analyzed as retrospectively.

RESULTS

2879 (68.3%) women in 4221 are using family planning methods, the 1342's of (31.7%) are not using any method. 1851 of using family planning methods (64.3%), modern methods in 1028 (35.7%) are using traditional methods. The modern method 719 (17.0%) tüp ligation, 560 (13.2%) have a condom, 373 (8.8%) IUDs, 166 (3.9%) of the pill, 33 (0.78%) use injection method. Most of the women using traditional methods, withdrawal method 995 (23.5%) were used. The reasons for women not using contraceptive method; 414 (30.8%) don't want to use the method, 274 (20.4%) of them women want to stay, 267 (19.8%) were continuing the pregnancy, 185 (13.7%) have been identified as menopause, 158 (11.7%) is breast feeding, 44 (3.2%) of infertility.

CONCLUSIONS

Depending on family planning services are important in this regard to the needs of society in primary care services. In this study, the proportion of women using family planning methods is consistent with Turkey in general. (the rate of using modern methods 47.4%, the rate of using traditional methods 26%). To use family planning methods were close to the average rate in Turkey (26.5%). These results based on effective methods of training programs to increase the rate, to be extended to include anyone who needs and should also be permanent.

Anxiety and depression influences in therapeutic failure

Enrique Almenar Cubells, Laura Ruiz Pérez, Enriqueta Hernandez Hernandez, Alfredo Quiles Raga, Diana Diaz Gil, Oscar Perez Quintana, Jose Vicente Alcaide Domingo
Centro de Salud de Benifaio, Valencia, Spain

The object:

The study aims to answer the following questions:

- Knowing the current therapeutic failure in a medical quota.
- Find out if anxiety or depression (undiagnosed) influence compliance.

MATERIAL-METHODS:

Cross-sectional study on 217 patients treated at the Health Center Benifaio (Valencia) in the consultation of the family doctor with the diagnosis / ICD-9-401 Essential hypertension in both sexes, aged 18-95 years.

It was excluded from the study patients with secondary hypertension, which had severe chronic or acute illnesses, who had a diagnosis of mental illness, as well as patients with contraindications to antihypertensive treatment and pregnant or lactating.

Each patient the following validated tests were conducted: Test Morisky-Green Levine to assess the therapeutic failure. Abbreviated Scale Goldberg anxiety and depression to assess anxiety and depression and collected the following measures blood pressure, weight, height and waist circumference

RESULTS:

The average age of participants was 70.83 years and standard deviation of 11,107. 53.5% women and 46 men, %%; Obesity showed 46.1%, 44.7% overweight and 20% normoweight. The therapeutic failure stood at 37.3% and was significantly correlated with anxiety, present in 16.1% of patients. Depression was found in 22.1% and was not significant

CONCLUSIONS:

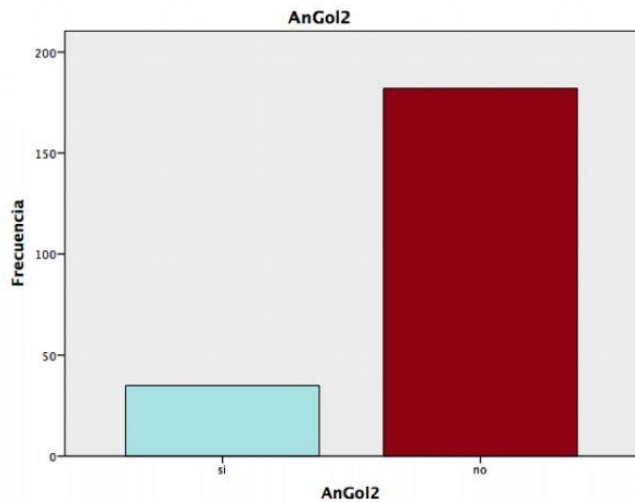

The prevalence of failure remains high, consistent with other studies. New measures to improve the therapeutic effect to be applied in the doctor's family doctor will be needed, as early diagnosis of mood disorder and anxiety that influence it.

Is Vitamin D Important Player In Hepatosteatosi In Childhood Obesity ?

Elif Özsü¹, Derya Tepe¹, Feyza Nur Topçu Yenerçağ²

¹Department of Pediatric Endocrinology, Samsun Obstetrics And Pediatrics Hospital, Samsun, Turkey

²Department of Family Medicine, Samsun Education And Research Hospital, Samsun, Turkey

BACKGROUND AND AIM:

Childhood obesity is one of the most serious public health problem. Obesity-related complications such as hepatic steatosis or type 2 diabetes can now be monitored even during early childhood. The aim of the study was to examine the relationship between vitamin D levels and obesity with hepatosteatosi in children.

METHODS:

A total of 128 children with obesity were included in this study. Hepatosteatosi (HS) was diagnosed using ultrasonography. Hepatosteatosi was graded. 25 hydroxyvitamin D, calcium, phosphate, alkaline phosphatase, parathormone, serum lipid level, glucose and insulin level were measured. Data were analyzed using 2 categories; obesity with HS and obesity without HS.

RESULTS:

A total of 128 children were studied. In our study group 42 % was male and the mean age 12,1±3,1 (range 4-18 years) Hepatosteatosi was identified in 39% (n: 50). There was a high prevalence (122/128 95%) of vitamin D deficiency or insufficiency; however, there were no significant associations between vitamin D level and HS. Uric acid, ALT, triglyceride level were significantly different in two groups.

CONCLUSIONS:

There is a high prevalence of vitamin D deficiency and insufficiency in children with HS, however, no association was found between vitamin D deficiency and HS.

Keywords: Vitamin D, Hepatosteatosi, Obesity

P-1104

Prevalence of Dysfunctional Family among students of a public and private elementary schools in Manila using FAMILY APGAR tool: A Pilot Study

Cherrielyn Recana Quezada

Ospital ng Maynila Medical Center

Family as the basic unit of the society, in its simplest form is composed of the parents and their children. With the recent researches indicate that family interaction contributes to a range of developmental outcomes. Family function measures the extent to which a family works as a unit; therefore it provides a rich mixture of stimuli to the children that often affect both physical and psychological development. The bumpy transition from childhood to adolescence phase is one of the most outwardly dramatic times of development and change in a child’s life. In line with this, the research aims to determine the prevalence of dysfunctional families using a sample population of 471 children aged 9 to 13 years old in two selected schools in the city of Manila.

A descriptive cross sectional study was conducted using the Family APGAR questionnaire. For this purpose, A total of 471 subjects were included, 388 were from the chosen public school and 83 were from private school. Using the Family APGAR scoring, family’s ability to cope and adjust to different situations concentrating on five components: adaptation, partnership, growth, affection and resolve were noted.

The study showed that 351 or 75% were considered to have highly functional families, while 120 or 25% have dysfunctional families. Out of those with dysfunctional families, only 5 were considered to have severely dysfunctional families.

With the aim of understanding the factors that lead to effectiveness of family interactions, the researcher proved that the APGAR questionnaire is useful in examining the specific relationships that make up family life and the children’s perception of their respective families and family functioning is appreciated already by this age group. In addition, the result was able to describe the characteristics of study population in terms of their age, gender, religion and body mass for age.

Keywords: FAMILY APGAR, school setting, youth, assessment tools, evaluation, child development

Figure 1. Distribution of subjects according to gender

This graph showed that among 471 subjects, 236 (50.11%) were females and 235 (49.89%) were males.

Figure 2. Distribution of subjects according to age

Distribution of Subjects according to age

Figure 2 shows the age distribution of the subjects and their corresponding percentages. Among the 471 subjects, 73 (15%) were 9 years old, 118 (25%) were 10 years old, 152 (32%) were 11 years old, 106 (23%) were 12 years and 22 (5%) were 13 years old.

Figure 3. Distribution of Public and Private School Respondents

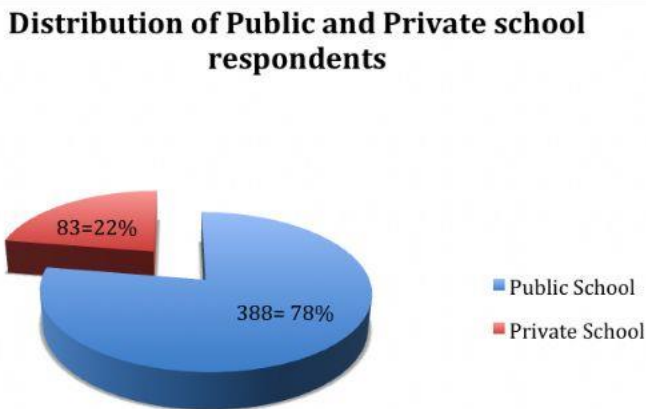

Figure 3. Distribution of Public and Private School Respondents Among the 471 subjects, 388 (78%) were from Fernando Ma. Guerrero Elementary School (public school) and 83 (22%) were from St. Pius Parochial School (private school). Equal distribution of the students from the private and public school was not met deemed necessary by the researcher as this study only aims to characterize and not compare between the private and public school subjects.

Figure 4. Distribution of subjects according to their respective religion

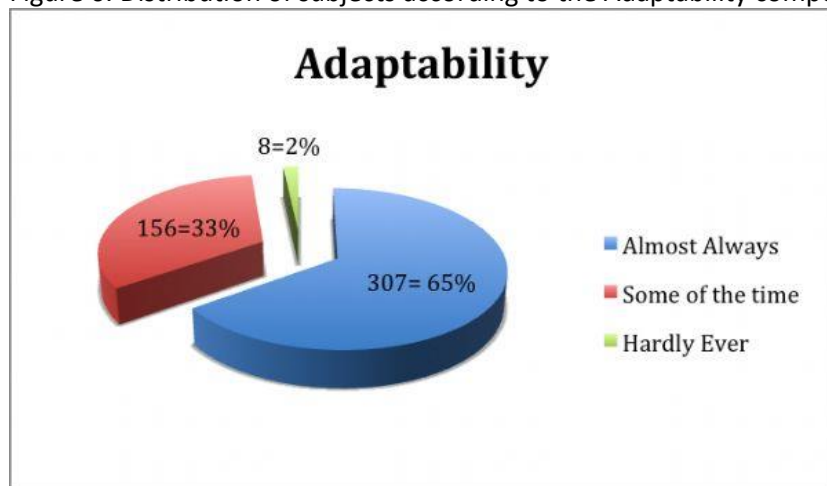

Majority of the subjects were Roman Catholics, followed by Born Again Christians. Interestingly, although the private school chosen is a Catholic School, students belonging to other religious sectors were also noted

Figure 5. Distribution of subjects according to body mass index for age

Majority of the subjects 289 (61%) were classified as healthy (healthy weight). 92 (19%) students were identified as overweight, 78 (17%) were obese and 12 (3%) were underweight. All subjects were classified using the Body Mass for Age (Fig. 5).

Figure 6. Distribution of subjects according to the Adaptability component of Family APGAR

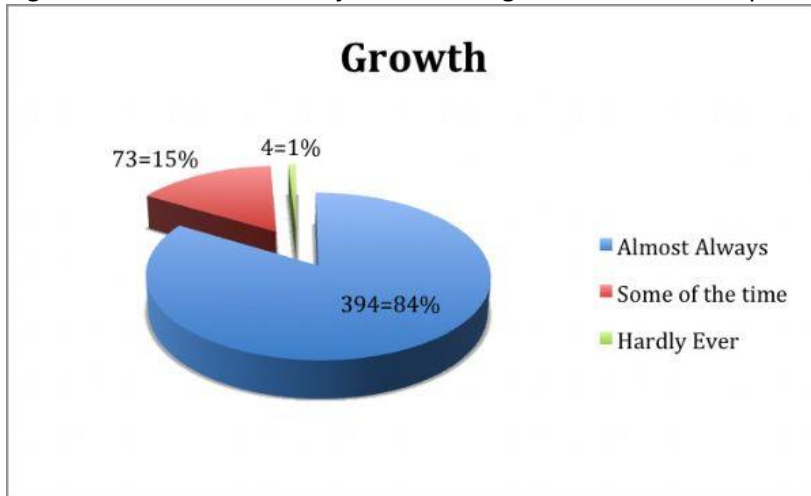

Among 471 subjects, 307 (65%) answered Almost Always when asked how satisfied they are for the support their family is giving them when something is troubling them. 156 (33%) answered some of the time and only 8 (2%) said they are hardly ever satisfied (Fig. 6).

Figure 7. Distribution of subjects according to the Partnership component of Family APGAR.

Among the 471 subjects 274 (58%) said that they are satisfied with the way their family discusses issues with them and helps in finding solutions for certain problems encountered. 177 (38%) answered that they are satisfied sometimes, while 20 (4%) said that they are hardly ever satisfied (Fig. 7)

Figure 8. Distribution of subjects according to the Growth component of Family APGAR

Majority of the subjects, 394 (84%) were satisfied as to how their family accepts and supports their wishes. 73 (15%) said they were sometimes satisfied and 4 (1%) answered hardly ever (Fig. 8).

Figure 9. Distribution of subjects according to the Affection component of Family APGAR

Among the 471 subjects 363 (77%) said that they are satisfied with the way their family expresses affection and responds to emotion such as anger, sorrow and love. Meanwhile, 99 (21%) are sometimes satisfied and 9 (2%) answered they are hardly ever satisfied on this parameter (Fig. 9).

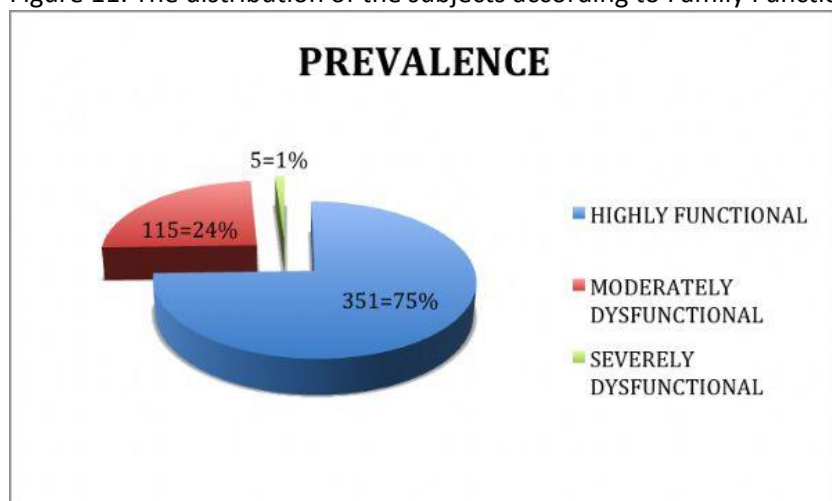

Figure 10. Distribution of subjects according to the Resolve component of Family APGAR

In addition, 323 (69%) of the 471 subjects were satisfied on how their family spend and spends their time together. 132 (28%) answered that they are sometimes satisfied and 16 (3%) answered that they are hardly ever

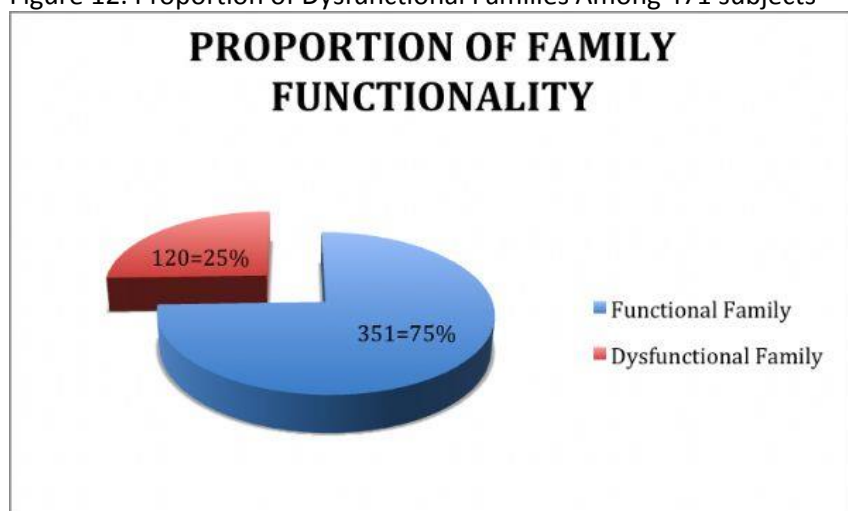

satisfied with this component (Fig. 10).

Figure 11. The distribution of the subjects according to Family Functioning.

Majority, 351 (75%) were classified to have highly functional families and are deemed to be satisfied with their respective family dynamics. Only five (1%) among the 471 subjects were classified to have severely dysfunctional families. Meanwhile, 115 (24%) were moderately found to have moderately dysfunctional families.

Figure 12. Proportion of Dysfunctional Families Among 471 subjects

For the purposes of this study, those with moderately dysfunctional and severely dysfunctional families will be lumped into simply dysfunctional family As children enter early adolescence, they begin spending more unsupervised time with friends and other peers (Brown, 1990; Larson & Richards, 1991). In fact, time spent with peers during early adolescence can often eclipse time spent with parents and other family members (Csikszentmihalyi & Larson, 1984). Early adolescents also become more concerned about peer acceptance and begin to turn to their friends more often as sources of advice and comfort (Gould & Mazzeo, 1982). In some ways, it appears that children's increased orientation toward peers during early adolescence is at the expense of their closeness to their parents. Steinberg and Silverberg (1986) found that whereas the percentage of peer-oriented children increased from late childhood to early adolescence, the percentage of adult-oriented children decreased. They speculated that during this period, children "trade" a dependency on parents for a dependency on peers. In fact, a converging body of research has supported that children disengage and distance themselves somewhat from their parents during early adolescence.

Table 1. Distribution of male and female subjects according BMI for Age Classification

Classification	MALE	FEMALE	Total
OBESE	47	31	78
OVERWEIGHT	41	51	92
HEALTHY WEIGHT	140	149	289
UNDERWEIGHT	7	5	12
Total	235	236	471

When compared, it was found that more males were found to be obese. But more females were found to be overweight and within the healthy weight category (Table 1)

Table 2. Distribution of the subjects according to age and Family APGAR classification

AGE	% Frequency	Highly Functional	Moderately Dysfunctional	Severely Dysfunctional	Total
9	15%	56	17	0	73
10	25%	99	19	0	118
11	32%	119	33	0	152
12	23%	66	36	4	106
13	5%	11	10	1	22
Total	100%	351	115	5	471

This table shows that subjects who were classified as part of "severely dysfunctional" families were from ages 12 and 13. Also half of the 13 years old subjects classified their respective families as dysfunctional. Meanwhile, majority of lower age group still classified their family as highly functional.

Relationship Between Red Cell Distribution Width and Mean Platelet Volume with Asthma

Lutfullah Cakır¹, Gulali Aktas², Ozgur Enginyurt¹, Recep Akgedik³

¹Department of Family Medicine, Ordu University Faculty of Medicine, Ordu, Turkey

²Department of Internal Medicine, Abant Izzet Baysal University Faculty of Medicine, Bolu, Turkey

³Department of Chest Diseases, Ordu University Faculty of Medicine, Ordu, Turkey

BACKGROUND & AIM: Asthma is a disorder characterized with chronic inflammation of the airways. MPV and RDW are parts of routine hemogram test and they have been shown to be related with inflammation. We aimed to study relationship between these hemogram parameters with asthma in asthmatic patients and to compare with healthy subjects.

METHODS: 38 patients with asthma and 38 healthy volunteers enrolled into the study. Laboratory tests for patients with asthma were performed in stable period of the disease. Healthy volunteers had no known chronic or acute conditions.

RESULTS: Age, sex and basic laboratory tests were not significantly different between study groups. However, MPV was significantly decreased and RDW was significantly elevated in patients with asthma compared to control subjects. Table 1 shows general characteristics and laboratory data of the groups.

CONCLUSIONS: In conclusion, we think that RDW and MPV shall yield diagnostic value in asthma. However, further prospective studies with larger population are needed to confirm our results.

Keywords: RDW, MPV, Asthma

The Effects of Education about Osteoporosis on Knowledge and Attitude of the High School Students

Oğuz Yılmaz¹, Yılmaz Cankurtaran¹, Nuran Ozciftci¹, Ahmet Cekic¹, Selin Bulut², Vildan Mevsim²

¹Faculty of Medicine, Dokuz Eylul University, Izmir, Turkey

²Department of Family Medicine, Dokuz Eylul University, Izmir, Turkey

Background

Osteoporosis is closely related with paediatric years, which is the critical period for bone growth and development. The timing for attainment of peak bone mass is not yet known, however, it is thought to be near complete by the end of adolescence. Although 60-80% of the variability in peak bone mass is attributed to genetic variability, environmental factors such as nutrition and exercise are also thought to have an important role influencing peak bone mass and the later risk for osteoporosis. Considering the early age at which peak bone mass is attained, preventive measures for osteoporosis should begin in childhood. Education of adolescents will lead to better understanding of concept of "bone health".

Method

The research is an interventional study. The intervention was done in 102 first and second grade students of a high school. A survey consists of questions about knowledge, attitude and behaviour about osteoporosis was implemented. After that, an education was given on osteoporosis. After the education the survey was implemented again.

The student who attends the lecture is required to prepare a project based on osteoporosis in one month. There is no obligation on method selection. Preparing a project is going to effect the knowledge and attitudes about osteoporosis.

The analysis was done with the SPSS 15.0 software, the descriptive statistics and the T test for dependent groups was used.

RESULTS:

The 41.2% of the participants were female. The average age is 14.8±0,75. After the education the knowledge and attitude scores increased 38.2% (p=0,000) and 22,8(p=0,000) respectively. Projects prepared by students were awarded in four areas: music, banner, slogan and story.

Conclutions

The study showed that the high school students' knowledge and attitude is insufficient and can be improved with

education.

Keywords: osteoporosis, adolescence, intervention study, peak bone mass

Relationship Between Social Support And Anxiety Levels Among Ondokuz Mayıs University Medical Students

Feyza Parlak Kabakcioglu, Fusun Aysin Artiran Igde, Mustafa Fevzi Dikici

Department of Family Medicine, Ondokuz Mayıs University, Samsun, Turkey

OBJECTIVE: This descriptive study was planned to determine related factors with levels of social support and the anxiety.

METHOD: The study was conducted by the Department of Family Medicine of Ondokuz Mayıs University in Samsun between March 2 and May 15, 2015. Data were collected by using a questionnaire prepared by the researcher to determine the sociodemographic characteristics, Multidimensional Scale of Perceived Social Support (MSPSS) to determine student's social support levels and Beck Anxiety Inventory (BAI) for measuring student's anxiety levels. Data were analyzed using SPSS version 20 statistical software.

RESULTS: Among 340 participants 55,6% (n=189) was females, 44,4% (n=151) was males. The mean age of students was $20,87 \pm 2,52$ years. The mean score of the MSPSS for all students was $62,42 \pm 14,74$. For females it was $63,56 \pm 14,76$ and for males was $60,99 \pm 14,63$. Although the females' mean score of the MSPSS is slightly higher than males' mean score, this difference did not reach statistical significance ($t=1,63$, $p=0,11$). The mean score of the BAI for all students was $11,24 \pm 10,28$. For females it was $11,59 \pm 10,24$ and for males was $10,80 \pm 10,34$. There was no statistical difference between female and male students. ($t=0,7$ $p=0,48$). Based on the BAI cut off point, 178 (52,4%) students were suffering from anxiety and their mean score of the MSPSS was $60,07 \pm 15,62$. For students who has normal anxiety level on the BAI (n=162) the mean score of the MSPSS was $65,00 \pm 13,27$. Negative correlation is found between social support and anxiety level ($p=0,02$).

CONCLUSION: Mental health of university students is one of the important components of public health. Anxiety can adversely affect quality of life. Improving social support is required to help university students become as more healthy individuals.

Keywords: anxiety; social support; students, medical

White Blood Cell Levels of Patients with COPD in Acute Exacerbation and Stable Periods

Mükremin Er¹, Samet Uludağ², Tuncer Kılıç², Furkan Dağcıoğlu², İrep Karataş²

¹Department of Pulmonology, Yıldırım Beyazıt University, Ankara, Turkey

²Department of Family Medicine, Yıldırım Beyazıt University, Ankara, Turkey

INTRODUCTION: Chronic Obstructive Pulmonary Disease (COPD) is a major cause of chronic morbidity and mortality throughout the world. Chronic airflow limitation caused by small airway disease and parenchymal destruction is characteristic for COPD. White blood cell (WBC) count is a marker of inflammation. The aim of this study is comparing white blood cell counts in stable and exacerbation periods of COPD.

METHODS: 35 patients (25 male, 10 female) with exacerbation of chronic obstructive pulmonary disease admitted to Atatürk Training and Research Hospital in the last 5 years were included to the study and WBC values on admission and discharge were evaluated of patients who were hospitalized for at least 7 days. The results were evaluated with a 95% confidence interval, and a P value < 0.05 was considered significant.

RESULTS: The mean age of the patients was 68.09 ± 9.84 , mean duration of hospitalization was found to be $11,8 \pm 3,8$. Average WBC value in acute exacerbations is 9455 ± 3518 , 9119 ± 3260 for stable period; whereas the difference wasn't statistically significant ($p=0,3$)

DISCUSSION: COPD is a common disease that family physicians encounter frequently. Our results reveals no correlation between WBC count and exacerbation of COPD in contrast with the stable period. Although COPD is an inflammatory disease, WBC levels don't increase as expected. So WBC count is not supposed to be a marker for acute exacerbation of COPD.

Keywords: WBC, COPD, Exacerbation, Stable

P-1109

Adherence to cardiovascular risk factors correction in patients with subclinical hypothyroidism

Victoria I Tkachenko, Christine M Kuharchuk

Shupyk National Medical Academy of Postgraduate Education

Background. Subclinical hypothyroidism (SG) is accompanied by increased levels of cholesterol dislipidemia and hypertension. A number of studies demonstrated that normalization of TSH during L-thyroxine therapy not always lead to removal of this dysfunction and need additional cardiovascular risk correction.

The aim of study: to analyze the adherence to cardiovascular risk factors correction in patients with subclinical hypothyroidism.

METHODS: 51 patients with SG were examined (45 women and 6 men, age $44,65 \pm 8,96$ years), average length of SG $6,09 \pm 4,68$ years. Blood pressure (BP) control, clinical and laboratory examination (blood chemistry, lipidogramme), retrospective analysis of outpatient cards, survey about cardiovascular risk factors and adherence to the prevention were conducted. Statistical analysis was performed by using Excel 2007.

Results. The 58.8% patients with SG (TSH $5,18 \pm 2,75$ when $N=0,17-4,05$) and average levothyroxine dose $112,5 \pm 32,7$ mg per day had dyslipidemia, the average level of cholesterol was $5,72 \pm 2,06$ mmol/l. Among the patients with dislipidemia, only 30% (9 people) took prescribed lipid-lowering therapy. The significant correlation was noted between TSH levels and total cholesterol values ($p < 0,05$). In addition, 52.9% (27 people) patients also had another cardiovascular risk factor – hypertension during $8,06 \pm 5,34$ years, but despite of antihypertensive therapy use, the blood pressure target 140/90 mmHg were reached only in 62,96% of patients (systolic BP was $140 \pm 19,21$ mmHg and diastolic BP= $88,81 \pm 11,07$ mm Hg), 66,67% of patients assigned they independently change the dose of the drugs, 25.92% of patients noted that often pass reception, 29.63% of patients rare missed antihypertensive drug, 3.7% of patients ignore it.

CONCLUSION: Patients with subclinical hypothyroidism have high cardiovascular risk despite Thyroxin therapy and low adherence to antihypertensive and lipid-lowering treatment. General practitioners should pay more attention to prevention of cardiovascular disease in patients with subclinical hypothyroidism and also check TSH level in patients in patients with dislipidemia.

Keywords: adherence, cardiovascular risk factors, subclinical hypothyroidism

P-1110

Mechanisms of dyslipidemia progression in patients with coronary heart disease and intestinal dysbiosis

Victoria I Tkachenko, Olga S Busygina

Shupyk National Medical Academy of Postgraduate Education

Background. The coronary heart disease (CHD) is the main clinical form of arteriosclerosis and is characterized by lipid metabolism disorders. Concomitant intestinal dysbiosis in patients with CHD is accompanied by modifications of lipid metabolism and progression of dyslipidemia. The mechanisms of lipid metabolism in these patients need to be studied.

The aim of the study was to examine the factors contributing to the progression of the blood lipid spectrum in patients with CHD and intestinal dysbiosis.

Methods. The study involved 106 patients with CHD and intestinal dysbiosis of 1-3 stage, age 50-65 years (63 men and 43 women) with body mass index (BMI) of 25-39.9 kg/m². The study excluded patients with inflammatory diseases, systemic diseases, diabetes, cancer. The blood levels of total cholesterol (TC), low density lipoprotein cholesterol (LDLP), triglycerides (TG), blood levels of insulin and factors of systemic inflammatory response - C-reactive protein (CRP), interleukin 6 (IL-6), fibrinogen were studied. Statistic – with Excel 2007.

Results. The levels of atherogenic lipoprotein fractions – LDLP cholesterol and TG - significantly correlated with BMI, blood levels of insulin, CRP and fibrinogen ($p < 0,05$). Levels of LDLP cholesterol correlated with BMI ($r=0,57$; $p < 0,05$), insulin level ($r=0,55$; $p < 0,05$), CRP ($r=0,61$; $p < 0,05$), fibrinogen ($r=0,60$; $p < 0,05$). TG levels correlated with BMI ($r=0,63$; $p < 0,05$), with insulin ($r=0,59$; $p < 0,05$), CRP ($r=0,49$; $p < 0,05$), fibrinogen ($r=0,44$; $p < 0,05$). Patients with more severe degrees of intestinal dysbiosis had more pronounced blood lipid disorders. Levels of LDLP and TG significantly correlated with the degree of intestinal dysbiosis - respectively ($r=0,48$; $p < 0,05$; $r=0,39$; $p < 0,05$).

Conclusions. The weight gain, hyperinsulinemia, factors of systemic inflammatory response took participation in

the mechanisms of the dyslipidemia progression in patients with coronary heart disease and intestinal dysbiosis. Increased intestinal dysbiosis is associated with a progressive disorder of blood lipid spectrum and has to be taken into account.

Keywords: coronary heart disease, dyslipidemia, intestinal dysbiosis

⁵Mustafa Kemal Üniversitesi

BACKGROUND: We aimed to investigate the attitudes toward vaccination and influencing factors among health care professionals.

MATERIAL-METHODS: This is a cross-sectional multi-center study. The study universe was composed of 1220 doctors and 1650 nurses. The questionnaire which was sent to the participants through e-mail included the questions about demographic characteristics, sources of knowledge about influenza and likert type questions about the factors influencing vaccination. Data were analysed with SPSS 22.0.

RESULTS: 187 doctors and 455 nurses participated in the study. Of the participants, 72% stated that they had high risk for influenza however 9% reported vaccination every year, 14% had the vaccine this year. Vaccination ratio was higher among males ($p < 0.05$). Vaccination rate increased as working years increased. Risk perception was significantly higher among the vaccinated subjects. A statistically significant difference was not detected between groups with regard to believing alternative medicine. The subjects who did not have vaccination think that natural methods are better than vaccination. Beliefs were seen not to affect vaccination. The motivating factors were found as the recommendations of Ministry of Health, having knowledge and free availability of the vaccine.

CONCLUSION: Ratio of vaccination against influenza is low. It was concluded that even health care professionals need information about regular vaccination at their own institutions and potential side effects.

"Awareness Of Patients Who Plan To Use Corticosteroids For A Long Term About Osteoporosis"

Evrım Kardelen Dizdar¹, Ediz Yıldırım¹, Hüseyin Can², Zeynep Ay², Mustafa Gökhan Dizdar³, Azize Dilek Güldal¹

¹Department of Family Medicine, Dokuz Eylül University Faculty of Medicine, İzmir

²Department of Family Medicine, Katip Çelebi University Faculty of Medicine, İzmir

³Department of Forensic Medicine, Manisa Directorate of Forensic Medicine Institute, Manisa

"INTRODUCTION:

Osteoporosis is an important health issue. Cortisone increases risk of osteoporosis. To prevent osteoporosis, precautions such as exercise or calcium support should be considered, especially with long term use. The objective of our study is to determine the risk awareness of patients who plan to use corticosteroids for a long time and factors related with.

METHOD:

Cross-sectional study was done with patients followed in two university hospital outpatient clinics and planned to use long term corticosteroids. A survey which includes demographic features, and life style questions and the Osteoporosis Health Belief Scale (OHSB) is applied. Descriptive statistics and hypothesis tests were done by using SPSS 15.0 program.

RESULTS:

The mean age was 49.97 and the 77.3% of the participants were women. 40.1% were high school or above graduates. Women in whom bone density measurement made more frequently ($p=0.000$), are diagnosed with more osteoporosis ($p=0.006$). The number of people who knew that cortisone increases osteoporosis were higher at the ones who had higher income ($p=0.036$). 45.3% of the patients did not consume calcium, 60.5% did not use D vitamins, 65.1% did not drink milk, 43% never had any exercises and 28.5% never went out for the sun. 45.9% of them were never informed about the side effects of cortisone by any health officer. Sense of OHSB awareness was higher at women ($p=0.001$) and similarly it was also higher at participants in whom bone density measurement were made ($p=0.012$). The total points of the ones who had lower educational status were higher. There was a significant relationship between the OHSB total points and the duration of corticosteroid usage ($r=0.283$, $P=0.000$).

CONCLUSION:

In our study, it was observed that patients who begin to use corticosteroids are not informed of osteoporosis adequately and do not take required precautions."

Knowledge and Attitudes of Pregnant Women and Their Postpartum Behaviors about Breastfeeding

Burcu Aslan, Mehtap Kartal

Department of Family Medicine, Dokuz Eylul University, Izmir, Turkey

In Turkey, although nursing rates are high, the rate of exclusive breastfeeding (EBF) in the first six months is low. Our aim was to determine the knowledge and attitude of mothers about nursing and their behaviors about exclusive breastfeeding in the first six months.

This study has a cross-sectional analytic design where initially 789 pregnant women at third trimester applied to the Pregnant Outpatient Clinics of Medical Faculties of Dokuz Eylul and Izmir Katip Celebi Universities, between 01.04.2014-31.05.2014 were included. All were asked for sociodemographic characteristics, knowledge about breastfeed and nursing, postpartum breastfeeding plans. In the second phase, all women were called when babies reached six months of age and 610 mothers completed the questionnaire related to birth, status of breastfeeding.

Their mean age was 28.80±5.763 (Range:16-44) years. All of pregnant wanted to breastfeed, 78.3% planned to complete EBF and 51.7% planned to nurse for first 19-24 months. After birth, 61.6% of the mothers, who were still breastfeeding, indicated that they will continue to breastfeed for 19-24 months. EBF ratios of babies for the first and sixth month were 51.1% and 16.1%, respectively. Mother’s history about breastfeeding had a positive impact on EBF plans during pregnancy and EBF behaviors at sixth month. Mothers, who nursed their previous babies less than 12 months, were planning to nurse their current babies for a shorter time than the mothers who nursed more than 12 months. When all the mothers included, it is found that nursing plan in the pregnancy period had a positive impact on plans and behaviors about maintaining breastfeeding in postpartum period. Positive breastfeeding experience of the women in their first pregnancy affects their nursing behavior for next babies. It’s an important clue for daily practice of family physicians’ breastfeeding consultancy to increase EBF ratios for future healthy generations.

depression, anxiety and stress state in mothers of children with cerebral palsy with or without epilepsy

Oktaç SARI¹, Mutluay ARSLAN², Ümit AYDOĞAN¹, Emrah BOYACIOĞLU¹, Sebahattin VURUCU²

¹Department of Family Medicine, Gulhane Military Medical Faculty, Ankara, Turkey

²Department of Pediatric Neurology, Gulhane Military Medical Faculty, Ankara, Turkey

BACKGROUND&AIM: Cerebral palsy(CP), developed as a result of nonprogressive brain damage is defined as the tone and posture disorders. Prevalence is reported to be 1.0 to 2.4 per 1000 live births. 25-80% of patients have additional disease other than posture and movement disorders. Any problems arising in children with CP bring both physical, psychological, financially need significant loads on parents. We investigated the emotional state of the parents of patients with cerebral palsy accompanied by epilepsy and not.

METHOD: This study was conducted on parents of patients diagnosed with CP, outpatients applied to Pediatrics Neurology Clinic by Gulhane Military Medical Academy(GMMA) Department of Family Medicine. The children's diagnosed with CP, age, gender, age-at-diagnosis, etiologic factors, the type of CP, CP's degree according to the Gross Motor Function(GMF) Classification was recorded. Afterwards, Depression Anxiety Stress Scale(DASS-42) was used for parents.

RESULTS: Total of 37 patients with CP, 23 patients (62.2%) had comorbid epilepsy. The mean age was 7.5 ± 3.3 (2-17) [CP: 7.4 ± 2.8 (3 to 13.5), CP+Epilepsy: 7.6 ± 3.6 (2-17)]. With CP children's 64.3% (n=9), and children's with epilepsy+CP 73.9% (n=17), hypoxia and/or prematurity as etiologic factors were encountered. According to the type of CP; 89.2% (n=33) of cases were spastic type (in 56.8% of them (n=21) types of spastic tetraplegia). According to GMF, nearly half of CP patients (45.9%, n=17) were level 5 (even assistive devices using, they are very limited in self-forth movement).

According to the parents of the DASS-42 points; with CP children's parents (n=5/14, 35.7%), CP+epileptic children's parents (n=2/23, 8.6%) had advanced symptoms of depression. Parents of children with CP (n=5/14, 35.7%), CP+epileptic children's parents (n=5/23, 21.7%) had high levels of anxiety symptoms. Symptoms of stress; the parent's with CP children (n=5/14, 35.7%), CP+epileptic children's parents (n=1/23, 4.3%) was advanced and very advanced. Statistical difference wasn't determined between two groups in terms of depression anxiety and stress (respectively; $p=0.297$, $p=0.246$, $p=0.50$).

CONCLUSIONS: CP, which requires a multidisciplinary approach, besides serious problems in children, brings the parents especially mothers of important psychological problems is a disease that leads to a decrease in quality of life. Therefore, providing psychological and social support should be among the important objectives to protect the psychological well-being of mothers.

Keywords: cerebral palsy, epilepsy, mood of mothers

P-1115

Burnout Syndrom and Job Satisfaction among Family Medicine Resident Doctors

Ayşe Didem Esen, Gülay Arıcı, Gözde Nizamoğlu, Ezgi Kaçar, Seçil Arıca

Department of Family Medicine, Istanbul Okmeydani Research and Training Hospital, Istanbul, Turkey

BACKGROUND: The aim of this study was to assess levels of burnout syndrom and job satisfaction among family medicine residents and to reveal their relations with different variables, like socio-demographic features, life style, qualities of working areas

METHOD: Family medicine resident doctors working in Okmeydani Research and Training Hospital and Şişli Etfal Hamidiye Research and Training Hospital are included in our study. The survey comprised of three parts (A) Sociodemographic data form and a questionnaire about personal lifestyle, habits, social and academic life, working conditions. (B) Maslach Burnout Inventory (C) Minnesota Satisfaction Inventory was administered to the resident doctors. Correlation analysis, independent sample t-tests are used as statistical methods.

RESULTS: 20 male and 26 female total 46 family medicine resident doctors take part in our study. Mean burnout scores were; MBI-EE (emotional exhaustion) 22.28 ± 5.60 , MBI-D (depersonalization) 21.43 ± 5.54 , MBI-PA (personal achievement) 30.93 ± 4.93 and mean satisfaction score was 58.63 ± 13.74 . Burnout and satisfaction scores were not affected by gender and marital status. Having social activities associated with high satisfaction ($p=0.012$) and MBI-PA ($p=0.001$) scores and low MBI-EE ($p=0.026$) scores. Feeling having support from hospital executives associated with high satisfaction ($p=0.048$) and low MBI-D ($p=0.014$) scores. Sporting regularly associated with low MBI-EE ($p=0.046$) scores. Having the idea of education content and quality is adequate was associated with high satisfaction ($p=0.036$), low MBI-D ($p=0.017$) scores. Following academic literature regularly is associated with low MBI-D ($p=0.034$) scores. Planning to change the clinical residency branch is associated with high MBI-D ($p=0.007$) scores. There was statically significant negative correlation between age and MBI-EE ($p=0.047$) and MBI-D ($p=0.029$) scores.

CONCLUSION: Burnout levels may decrease and also job satisfaction levels may increase among family medicine residents by having social activities, regulation of working conditions and education quality. Psychological support and arrangements in social, working, educational areas would effectively contribute to prevention of burnout syndrom and improvement of job satisfaction.

Acute disease consultation: consultation's reasons

Susana Sá, Susana Rios, Mariana Pinto Leite, Gonçalo Pereira, Miquelina Redondo

Unidade de Saúde Familiar Sem Fronteiras, ACeS Entre o Douro e Vouga I

INTRODUCTION: In Primary Care, the acute disease consultation (ADC) serves to respond to situations of acute illness or escalation of chronic disease. However, there is often a misuse of the ADC, which may affect the accessibility of users that effectively need this consultation.

OBJECTIVES: To evaluate the correlation between the reasons given by the user in the admission sheet and the motives (S-Subjective; ICPC-2) recorded in the health care informatics software (SAM[®]) by the doctor; identify the non-valid reasons most frequently recorded in ADC; characterize the population that uses the ADC and evaluate the quality of medical records.

METHODS: Cross-sectional observational study, descriptive and analytical; Period analyzed: 01-02-2014 to 01-31-2015; Variables: gender, age, consultation reasons and motives (S). Information collection: SAM[®] and admission sheet; Compilation of the data and statistical analysis: Microsoft Excel[®]. The test pilot was made at 01-02-2014. Informed consent was required for the participation in the study. It was also requested permission for the realization of this research work to the family health unit coordinator. All ethical principles were respected.

RESULTS: Of a total of 5707 ADC, were selected randomly 1251 ADC. Overall, there was a conformity between the reasons given by the patient in the admission sheet and the motives codified by the doctor; The medical records were in general satisfactory; About 1/5 of ADC reasons weren't valid (22.5%)—the most recorded motive

(S) was Results Tests/Procedures (A60); There was a predominance of females (63%) and the age groups of 19-45 years (35.6%) and 46-65 years (33.3%) in these consultations.

DISCUSSION: The investigators concluded that is essential to consolidate among the users of primary care the clinical conditions that justify the use of the ADC, in order to minimize the not valid reasons and to ensure the greatest accessibility to the ADC. Medical records, based on ICPC-2, can still be improved.

Keywords: acute disease consultation; accessibility; medical records; consultation's reasons

ACD valid and not valid reasons

ADC valid reasons:	ADC not valid reasons:
Acute illness with recent onset, less than 3 days of evolution	Clinical situations without acute complaints or escalation of chronic symptoms/ signs
When the user is absent from work due to acute illness	To show medical exams
Recent deterioration of chronic illness (in the last week)	To request credentials for medical exams, for physiotherapy or other treatments
Intention to make voluntary interruption of pregnancy/ Miscarriage	To request credentials for evaluation on hospital consultation
After evaluation, by the nursing team, of situation that deserves medical evaluation	To request medical statements/ reports (health/ disease certificates or others)
Prescription/ delivery of emergency oral contraceptives	To renew work incapacity certificate
Clinical situations related to recent exposure to infectious diseases capable of prevention or treatment (tuberculosis, meningitis, chicken pox ...)	To renew chronic medication or others prescriptions

10 Years (2001-2010) Evaluation Of Cancer Cases At Dicle University

Necmi Arslan¹, Erkan Kibrisli¹, Hamza Aslanhan¹, Ahmet Yilmaz¹, Seyhmus Kaya², Ugur Firat², Mehmet Halis Tanriverdi¹

¹Department of Family Medicine, Medicine Faculty, Dicle University, Diyarbakir, Turkey

²Department of Pathology, Medicine Faculty, Dicle University, Diyarbakir, Turkey

AIM: The incidence of cancer is increasing in our country and in the world. The treatment of cancer is difficult, time wanting and costly. The most important step of treatment is early diagnosis. The incidence of these cases and differences with regards to gender and age groups are important for family physicians when evaluating patients in their regions.

METHOD: The biopsy reports of patients diagnosed malignant between 2001 and 2010 years, in the department of pathology at Dicle University Faculty of Medicine, were analyzed retrospectively. RESULT: A total of 3624 patients were examined with regards to age, sex, topography of material and biopsy results according to the pathologic diagnosis. 41.7% of cases were female and 58.3% were male. When examined the topographic distribution of received cases The most common type of cancer was observed in lung cancer %11.9 (Table 1). The cases were examined separately in men and women. In men the lung cancer was the most common with proportion 18.5%, while in women the breast cancer 23.1% were observed (Table 2). The incidence of cancer was the highest between 50-60 years of age.

CONCLUSION: Family medicine is a medical specialty, that is individual, preventive, holistic, multidisciplinary. Therefore, for a family physician it is necessary to know specific diseases of the area where serves in and has to know to take the necessary measures to determine in advance of these diseases. In our study, we tried to

determine by using the data of Dicle University Hospital, the biggest one in the region, which types of cancer contract of our people the most common in the geography we live with. We believe that this information would be guide for our works which we will do later, to protect our patients and to diagnose of diseases early.

Career pathways for General Practitioners: linking life roles, work values and career stage

Lesley Margaret Piko

ACT Medicare Local Ltd

BACKGROUND: General practitioners (GPs) deal with increasingly complex health conditions and treatments, and an ageing population. However, once fully qualified, GPs are confronted with relatively flat career trajectories. Many GPs respond by working part-time on clinical activities, in combination with non-clinical life roles. GPs make choices about the relative importance of these roles within the context of a career in general practice.

AIM: The aim of this project was to explore the connections between career stage, work values, life roles, gender and age in decisions by doctors to limit their hours in clinical work.

METHOD: This research examined career decisions GPs made after working for several years in their chosen profession. Twenty GPs participated in semi-structured interviews and a pilot survey. They were asked about their work history, life roles, work values, career concerns and work intentions. The survey collected data about values and career concerns.

RESULTS: The findings of this project provide insights into the way in which work values and career concerns combine to influence mid-career choices by GPs, especially decisions to limit their involvement in clinical work. In the absence of an upward clinical career path, many GPs found development in other roles in spheres such as business, research, policy development, family and leisure. Several career pathways were found including the traditional career as a GP and the more diverse portfolio career model.

CONCLUSIONS: This research brings together factors which influence GP work life and examines them in the overarching framework of a professional career developing over time. An awareness of how GPs make mid-career decisions provides a basis for supporting their career development in an essentially flat career structure.

Piko Poster Career Pathways for General Medical Practitioners

Career Pathways for GENERAL MEDICAL PRACTITIONERS: Linking life roles, work values and career stage

Lesley Piko, Australian Local of General Practice and Community Health, ANU Medical Centre, leslay.piko@anu.edu.au

General practice in the Australian health system
It could be even more difficult in the future to meet Australia's rising demand for primary health care. General medical practitioners (GPs) are dealing with increasingly more complex health conditions and treatments, and an ageing population. The average age of GPs is rising and a rise in GP numbers is looming. Approximately 80% of GPs are now working in groups or corporate practices and their career pathways are diverse. Once they are fully qualified, the ways in which GPs develop and progress their careers is less clear-cut when confronted with relatively flat career trajectories. Many GPs respond by working part-time on clinical activities, in combination with non-clinical roles.

AIM
This pilot project informs a larger study of career decisions which GPs make after working for several years in their chosen profession. The project's overall aim is to research the connections between work values, stage of career, life roles, gender and age in the decisions GPs make about their clinical work.

METHOD
Purposive sample for pilot stages
Semi-structured interviews with GPs (n=17)
Survey of career concerns and work values (n=17)

	Frequency	%
Male	4	23.5%
Female	13	76.5%
<40	6	35.3%
40-50	11	64.7%
>50	0	0%

Participants were asked about their academic and employment history, family circumstances, work values, and issues they are concerned about in developing their career.

Content was analysed using grounded theory methodology.
The Physician Values in Practice Study (PVP) and Adult Career Concerns Inventory-Short Form² were chosen for this pilot stage of the project.

CAREER PATHWAYS
Several pathways were found:
• Single, lower senior clinical positions
• Specialist, clinical + non-clinical roles
• Multiple clinical practices of same form
• Multiple roles, clinical + non-clinical at the same time
• Engaged, working in and out of clinical
• Non-work, working part-time, no fixed location
• Reciprocity, a back-up to support other interests
• Part-time and full-time participation

The different career pathways found in this pilot project provide insights into the way in which work values and career stage combine to influence choice made by GPs, especially decisions to vary their participation in clinical work. In the absence of an upward clinical career path, many GPs seek to enhance other non-clinical life roles in spheres such as business, research, education, policy development, family and leisure.

WORK VALUES
This research points to lifestyle factors and autonomy being of highest importance to GPs followed by passing on knowledge to new doctors.
Strongly influence between their personal and professional commitments (14 GPs);
Following a flexible work schedule (13 GPs);
Working a predictable number of hours (12 GPs).
A lot of people who suggest that they've got an interest in general practice that hasn't been entirely reciprocated in 2016. In other words, they will immediately see what I mean, when I say that for a lot of people their career path doesn't fit all of their reports about, you know that sort of stuff. I do something in the morning, they go, 'well, look at this, don't you?' And I have that point of view, a lot of your value propositions which may come across differently. They will see it as a new year - something that's coming, going over to get to holidays and do stuff. (GP14, 48min, 45min)

When you are a general practitioner as your main job, you're not really interested in the sort of stuff that's coming out of the industry. I don't think it's personal recognition really. So for all sorts of reasons I just don't respond. (GP16, 50min, 45min)

When they say they don't want to be a doctor, they're not saying they don't want to be a doctor. (GP17, 48min, 45min)

Having freedom to choose their own method of working (11 GPs);
Clear of the things that I do and to my capacity to determine my hours. (GP18, 50min, 50 min)

When I have and they don't have the hours and how I tell my patients and how many jobs I want to see per hour and what I want throughout the day. (GP19, 50min, 50 min)

Working and increasing new doctors (12 GPs);
How I see teaching is that not sharing the experience with them. (GP20, female, 44 min)

It's to give to make a difference to the next generation of doctors coming through. I suppose, to be able to offer... passed on knowledge. (GP21, female, 52 min)

DISCUSSION
Existing research relating to general practice in Australia, for the most part, deals with single aspects of a GP work life (e.g. satisfaction or well-being). There is little evidence of connections being made between these single aspects to the larger framework of a career development. Nor has the connection been made between time spent in different roles, work values, career stage, gender and age.
Workforce planning is essential for determining and designing policy options to ensure the supply of GPs to meet demand. An awareness of how experienced GPs make career-related decisions can inform workforce supply policy. It can also provide a basis for supporting the career development of a range of health professionals such as specialist pharmacists and dentists, who may work in an alternative way in essentially flat career frameworks.

P-1119

Aligning business and people in general practice

Lesley Margaret Piko

ACT Medicare Local Ltd

BACKGROUND: Approximately 80% of Australia’s general practitioners (GPs) work in group or corporate general practices, supported by practice managers, nurses and other staff. People are a key factor in these clinical practices achieving their business goals. People development is often seen as an activity of large businesses. However, greater attention to this issue by group practices could help retain experienced people within the primary health care workforce and ensure appropriately trained, motivated and managed staff are available.

AIM: The aim of this project was to explore how general practice business goals and the personal goals of GPs are being aligned to attract and retain GPs in clinical practice.

METHOD: Six case studies of general practices were conducted and ten GPs participated in semi-structured interviews and a pilot survey. Data were analysed to identify work values and the alignment between business and personal goals.

RESULTS: The case studies found that people management in general practice was for the most part limited to remuneration and payroll systems with little attention given to the personal development of people who worked in the practice.

This research also found that general practice business valued healthy business, healthy patients and healthy staff while GPs valued lifestyle, autonomy and service.

CONCLUSIONS: This research brings together factors which influence GP career development within the context of group general practices. GPs and non-clinical staff would benefit from career development, satisfying work experiences and financial remuneration that provide a better fit for their work lives and other interests. Business policies could support people within the general practice business in a way that aligns the goals of the practice with personal goals.

Keywords: Business management, workforce, career development

Piko Poster Aligning Business and People

Aligning BUSINESS AND PEOPLE in GENERAL MEDICAL PRACTICE

Lesley Margaret Piko, Academic Unit of General Practice and Community Health, ANU Medical School, Henty Professor, et al.

General practice in the Australian health system

Approximately 80% of Australia's general practitioners (GPs) work in group or corporate practices, supported by nurses and other staff. Little is known about how business and personal goals are aligned in general medical practice.

AIM

As part of a study of GP careers, I explored how general practice business goals and the personal goals of GPs are being aligned in the Australian Capital Territory (ACT) to attract and retain GPs in clinical practice.

METHOD

Purposive sample

- Case studies of general practice (n=6)
- Interviews with GPs (n=10)
- Pilot survey (n=10)
- Interviews with key informants (n=2)
- Review of literature

Data were analysed for conceptions of work values and the alignment between business and personal values within general practice.

FRAMEWORK

Work values are aspects of occupational life that contribute to job satisfaction, such as income, lifestyle, autonomy, providing service and achieving outcomes.

RESULTS

I found three peer-reviewed articles about work values in medicine (Australian doctors), Australian medical students and GPs (family physicians) but none of these connected personal work values to the general practitioner's business goals.

My case studies indicate that workforce management focuses on remuneration and payroll systems.

General Practices in the ACT

Practice Size	Number
2000-30	28
30-40	25
40-50	24
50-60	24
60-70	24
70-80	24
80-90	24
90-100	24

And fewer GP-owned or owned practices.

About 70% of Canberra's general practices are "solo" with less than four GPs. There is a shift of GPs towards larger practices because of higher commercial success and of lower costs.

Different models of general practice:

- Private business models owned by GPs
- For-profit business models owned by shareholders
- Not-for-profit community government general practices and clinics supported by government or charitable funding and in-kind contributions
- Health clinics within large government funded organisations

BUSINESS GOALS OF GENERAL PRACTICES

GPs join together in general practices, seeking the skills and infrastructure needed to achieve their goals for primary health care.

Healthy business:
Dr. [Name] (general practitioner, not GP doctor): "My practice is the business model" - to be staffed with enough doctors and nurses".
Practices seek the flexibility and adaptable resources to respond to changing patient and government demands.

Healthy patients:
While providing primary health care services to patients is seen as core to general practice, how this is achieved (cost, care in terms of performance, productivity, cost effectiveness, etc.) is debatable.

Healthy staff:
Attracting and retaining staff and workforce is a goal of business. For general practice in the ACT, more GPs, practice nurses and staff are needed but this may not be viewed as the most urgent. This situation highlights the importance of general practices in planning and managing their practice.
"Managing a general practice can be stressful... a practice might need help when their regular GP is not here... I have to do it" (Owner of a general practice-GP).

PERSONAL GOALS OF GENERAL PRACTITIONERS

My research predicts the lifestyle being of highest value to GPs, followed by autonomy from service. This agrees with a USA study of family physicians which reported service, lifestyle and autonomy as important but demotivated practice, reducing practice and management.

Lifestyle:
GPs said they wanted good work-life balance and time off when needed. In the ACT, 40% of GPs report having a second job.

Autonomy:
I asked to GPs who said they wanted to have control over when and how they work.

Service:
GPs said that working with people attracted them to general practice.
"I get working with a mixture of people and sometimes they become close" (General Practitioner-GP/MD).
"I prefer the interaction with patients and colleagues" (General Practitioner-GP/MD).

Remuneration:
The amount of acceptable remuneration for work. Most GPs agree the business side (not their work contract) is well understood. Few GPs thought remuneration was a good work and work-life.

DISCUSSION

In Australia, where GPs are choosing not to work alone, general practices can place more emphasis on managing their people to align business and personal aspirations.

Processes used to align:

- Design of work contract
- Scheduling of work
- Recruitment
- Performance monitoring
- Career development
- Succession planning

In the ACT, having organisations with different business goals and strategies to achieve them provides employment options for GPs.

Quote from a GP: "By giving the business right or that it spending resources is expensive and also profitable" (GP/MD).

P-1120

The frequency of urinary incontinence and effecting factors in women

Irem Kevser Cantürk, Hilal Abbak, Zuhal Aydan Saglam

family medicine

AIM:

To determine the frequency of urinary incontinence (UI) in women over 35 years old.

MATERIALS-METHODS:

Women ≥ 35 years old applying to Gynecology Department for general gynecological complaints between December 2013-January 2014 were invited for a questionnaire inquiring the presence and frequency of UI complaint. Demographic characteristics, intraabdominal operation history, number of pregnancies, smoking habit, associating chronic diseases and drug use were recorded and compared in women with and without UI.

RESULTS:

Of 163 patients (age: 49.4 ± 10.5 years; BMI: 29.7 ± 5.5 kg/m²) 94 had UI. 30 (31.9%) of women with UI had HT, 20 had DM (21.3%) and 8 had COPD (8.5%). The frequency of intraabdominal operation history was 66.2%. There was no relationship between smoking habit and UI ($p=0.811$). 69 women with UI (%18.4) had this problem 1-3 times in a day, 26 (%18.4) had 1-3 times in a week, 38 (%23.3) had 1-3 times in a month. UI was found significantly more frequent in multiparas as expected ($p=0.001$). The patients who has UI of total 94 patients 67 (%71.3) didn't apply to a doctor, 51 (%65.4) of them ignored ($n=43$; % 84.3) was explained. UI was found more significantly in the patients who has HT, DM and COPD (respectively; $p=0.003$; $p=0.016$; $p=0.021$)

Discussion and CONCLUSION:

UI is a common problem in females which is unfortunately being ignored by patients and doctors as well. While obesity, age, concomitant chronic diseases are the most common risk factors in most cases, post-menopausal women with additional history of multiparity, and intraabdominal operation who are attending to primary care unit for nonspecific reasons or for periodical examination should be questioned for UI.

Evaluation of thyroid function tests in patients admitted to the family medicine clinic for examination

Yılmaz Sezgin, Ali Emre Akgün

Sürmene State Hospital, Trabzon, Turkey

INTRODUCTION:

In the last thirty years, conflicting studies have been published, regarding the effects of iodine fortified nutritional advice, on the targeted populations. Both the studies suggesting that iodine supplementation is inadequate and the studies suggesting that iodine supplementation may lead to hyperthyroidism are available.

In this study we investigated the effects of iodine supplementation by retrospectively reviewing the records of the patients who admitted to the family medicine clinic.

MATERIALS-METHODS:

This study was a retrospective cross-sectional study. A total of 572 patients who admitted to Tonya state Hospital between September 28th 2012 and 17 May 2013, meet the inclusion criteria, and both TSH and T3 levels have been measured were included in the study. The mean values of TSH and T3 were compared with the population mean. In addition, the TSH and T3 levels were categorized according to the reference value and percent distribution rate was calculated.

RESULTS:

The ratio of T3 levels above population mean was 80.6%. The ratio of TSH ratio below the population mean was 88.1%. The means of those included in the study according to the T3 levels were significantly higher than the means of population ($p < 0.001$). The means of those included in the study according to TSH levels were significantly lower than the means of population ($p < 0.001$).

CONCLUSIONS:

In our study, higher T3 values in comparison with population means and lower TSH values in comparison with population means indicate that the T3 levels suppresses the TSH levels. These results suggest that majority of the patients who admitted to the family medicine clinic have been affected subclinically at hyperthyroidism level. As a result, given that pharmacological treatment for hypothyroidism is easily available, the rationale for implementing iodine supplementation programs for the treatment of endemic goiter should be questioned again.

Too early can be too late! Stroke in the young adult

Joana Carneiro¹, Sofia Correia Pinto², Inês Bento¹

¹USF Garcia de Orta, Porto, Portugal

²USF S.João do Porto, Porto, Portugal

Background & AIM: Recognizing the cause of a stroke in young adults is challenging and many studies have been trying to understand the etiopathogenesis behind it, which is undetermined in 35 to 42% of cases. The age range for which one is considered a young adult is not yet defined, but most studies consider patients up to 45 years of age. The aim of this study is to characterize the profile of a young adult who has had a stroke regarding sociodemographic characteristics, type of stroke, presence of risk factors and the clinical implications after this cardiovascular event.

METHODS: Descriptive cross-sectional study in two Primary Health Care Units in Porto, Portugal. The clinical process of patients who had had a stroke before or at 45 years of age was assessed, in particular the personal history, type of stroke, diagnostic tests and functional state. Arterial hypertension, diabetes, dyslipidemia, tobacco use, use of oral contraceptives and family history of premature cardiovascular disease were the risk factors taken into consideration. The presence of migraine, alcoholism, hyperthyroidism and pregnancy were also assessed. SPSS 20.0® was used for statistical analyses.

RESULTS: An association between atherosclerotic risk factors and stroke was established. However the importance of other factors such as genetics may also be implied in the etiopathogenesis of stroke in young adults, especially on those in which the cause is undetermined.

CONCLUSIONS: Primary prevention should be reinforced, modifiable risk factors should be regularly assessed and healthy life style habits should be promoted. Sensitizing health authorities, health care professionals and the general population about risk factors and early detection of stroke is essential and can eventually make a difference in outcomes.

P-1123**working conditions and the effects of demographic characteristics on sleep quality of doctors**

Sema Erdogmus, Gokcen Cerrah, Hasan Huseyin Mutlu, Zuhal Aydan Saglam

family medicine, istanbul medeniyet university goztepe training and research hospital, istanbul, turkey

INTRODUCTION: To evaluate the sleep quality of doctors

METHOD: This cross-sectional analytic study was carried out in 2014 at a tertiary hospital among 99 residents. Pittsburgh Sleep Quality Scale(PSQS) was performed. PSQS \leq 5 showed good quality of sleep and scores over 5 showed bad quality. Socio-demographic characteristics of participants were recorded and analysed with respect to their consumption of sleeping pills, cigarette and alcohol.

FINDINGS: The average age was 33.70 \pm 9.62; 58.6% were men. While 30.32% were working in surgical departments, 69.7% were working in internal medicine. 20.2% were smoking and 45.5% were drinking alcohol. Mean BMI was 23.77 \pm 3.70 and 26.03 \pm 2.64kg/m² for women and men respectively. Mean waist circumference was 82.95 \pm 7.19 and 91.98 \pm 7.19 cm for women and men resp. BMI and waist circumference of men were found significantly higher than women (resp. p<0.0005 ve p=0.001).

8.1% had chronic disease [HT/DM/HL; n=1/2/7]. 60 participants had \leq 5 shifts and 39 had >5 shifts per month. Total PSQS was 4.23 \pm 3.16. 68.7% of the doctors had PSQS \leq 5 and 31.3% had a PSQS score of >5. The mean PSQS were 4.81 \pm 3.29 and 3.41 \pm 2.81 for women and man respectively (p=0.028). In terms of surgery and internal departments, sleep quality was found to be 66.7%/69.6% good and 13.3%/30.4% bad respectively (p<0.05). For doctors having 5 or less shifts/month (n=60), the mean PSQS was statistically lower than those who had more than 5 shifts (n=39) (p=0.024).

DISCUSSION: Although inevitable, it is for sure that shifts have long term negative effects on sleep quality of doctors. It seems that female doctors have much more burden in daily life which is supported by the data that they require more sleeping pills. Bad sleep quality for doctors may cause errors in intellectual/metabolic activities and in critical decision making. This possibility should be taken into consideration in planning working schedules of especially female doctors.

Burnout syndrome among the residents of a university hospital

Zuhal Altınbaş, Hatice Esin Temiz, Zuhal Aydan Sağlam, Hasan Hüseyin Mutlu
family medicine

Background and AIM: To investigate the level of burnout and related factors among the residents of a university hospital.

METHOD: Sociodemographic data of 202 doctors were collected and Maslach Burnout Inventory was applied between December/2011-March/2012. Depersonalization (DP), decreased accomplishment (DA) and emotional exhaustion (EE) was investigated. In DP and EE subscales, high scores indicated high burnout level while in PA low scores were associated with high burnout levels. ANOVA and t-tests were used for statistical analysis. RESULTS: 56.4% were female; mean age was 28.6 years. 11% had chronic disease; 48.5% was married. 58.9% were currently doing compulsory medical service. Burnout Score (BS) was found significantly higher among bachelor residents compared to married ones. The smokers (25.7%) and alcohol consumers (29.7%) stated that they increased smoking and alcohol use due to work-related stress. BS was high also among the residents who increased smoking due to work-related stress. Lack of appreciation, lack of support from colleagues, lack of self-confidence, insufficient time for hobbies, lack of contentment with the chosen specialization and/or profession itself were the main factors for high BS. The prevalence of high scores was 55.4%, 34.6% and 9.9% respectively among the residents of internal medicine (IM), surgical departments (SD) and family medicine (FM). Working hours for SD, IM and FM were 288h, 273h and 254h per month, respectively. The mean workload of assistants in SD (288hrs) is significantly ($p=0.045$) higher than FM. The burnout levels of SD and IM were similar. However BS score of the residents of SD was higher than that of FM residents in all subscales and GT score. DA and BS scores of SD and IM were significantly higher than those of the FM residents.

CONCLUSION: Although associated with being bachelor, high Burnout Scores among SD and IM residents were highly associated with long working hours day and night and weekends. This makes it obvious that in Turkey the current Family Medicine Policy may be better without the negative influence of additional working hours for both physicians and patients.

Keywords: burnout syndrome, family medicine, workload

Are People With HIV Happier?

Zuhal Aydan Sağlam¹, Fatma Sargin¹, Rasim Volkan Ertaş¹, Aynur Rzayev¹, Hasan Hüseyin Mutlu¹

¹family medicine

²infectious diseases clinic

AIM: Comparison of quality of life(QOL) of a sample of HIV(+) patients with healthy people.

METHOD: QOL of volunteering HIV(+) patients attending to a university hospital between 2012-2013 were assessed with SF-36 and compared with 70 healthy controls. Sociodemographic data were collected. Using SPSS Version 17, the data were tabulated and compared with chi-squared tests and the means were compared by one-way t-tests and F-tests.

RESULTS: Among the 70 HIV(+) patients, 55 are male, 38.6% are under 35 years old, 58.6% are not married, 64.3% have HS education or more, 65.7% are employed, 54.3% have monthly income over basal wage. Sociodemographic characteristics were in match with control group except marital status. Among the HIV group, 45.7% were diagnosed less than one year ago and 38.6% were treated for a year or less. Also, 48.6% had some HIV training, about half by their physician and the others by NGO's. About half (47.1%) believe that they are well informed about HIV and 60% believe that they are sufficiently treated. A vast majority of the patients (77.1%) did not get any psychiatric treatment. The mean Physical Component Score (PCS) for the HIV group was 61.68 (± 8.43) which is significantly greater than the mean PCS (58.62 ± 10.69) for the control group ($p=0.017$). Similarly, the Mental Component Scores (MCS) were 53.10 (± 10.69) and 48.62 (± 9.57) respectively for the two groups ($p=0.005$). The mean scores of Physical Function (PF), Back Pain (BP), Vitality (VT), Social Functions (SF) were significantly higher for the HIV group than the control group (resp; $p=0.0065$; $p<0.005$; $p=0.0025$; $p<0.005$). These indicate that the HIV group had significantly better QOL on many scores than the control group, surprising the researchers.

CONCLUSION: The data at hand is insufficient to explain why HIV people have a higher QOL. It may be due to the fact that they are more likely to take risks to be happy. However, this needs to be verified by further research.

¹⁰Department of Family Medicine, Faculty of Medicine, Duzce University, Duzce, Turkey

Background & AIM: To evaluate the predictors of major adverse cardiovascular events (MACE) in a prospective population based study.

METHOD: This study included 153 participants aged >40 yrs with high and very high cardiovascular risk, and 50 participants aged >40 years with low cardiovascular risk according to the SCORE risk assessment. All the participants underwent a Doppler ultrasound examination of carotid intima media thickness (CIMT), echocardiographic examination, ECG recording and various biochemical analyses. High-sensitivity CRP (hsCRP) was measured with chemiluminescent immunometric assay, serum amyloid-A (SAA) protein, soluble intercellular

adhesion molecule-1 (sICAM), apolipoprotein-B (ApoB) were measured with ELISA method. eNOS single-nucleotide polymorphism was detected using polymerase chain reaction and restriction fragment length polymorphism methods (Figure 1). The follow-up was done 36 months after the baseline admission. MACE was defined as cardiovascular mortality or myocardial infarction or stroke.

RESULTS: Comparison of demographic, clinical characteristics and laboratory parameters among subjects with low risk SCORE and high risk SCORE were shown in Table 1 and 2. Comparison of demographic, clinical characteristics and laboratory parameters of subjects with and without MACE was shown in Table 3 and 4. Frequency of MACE was higher in high and very high risk group according to low risk group. There were no significant differences in eNOS gene polymorphisms between the risk groups and control subjects, and no significant association between eNOS gene polymorphisms and MACE was detected. Age, ejection fraction (EF), CIMT, hsCRP, ApoB, sICAM-1, and SAA protein levels were all significantly associated with MACE in univariate logistic regression analyses. Multivariate analyses revealed that age (OR:1.08, CI:1.02-1.15, p=0.013), EF (OR:0.94, CI:0.89-0.99, p=0.016), hsCRP (OR:1.36, CI:1.12-1.67, p=0.003) and sICAM-1 (OR:81.0, CI: 1.04-6320, p=0.048) levels were the only independent predictors of MACE (Table 5).

CONCLUSION: Higher age, hsCRP and sICAM-1 levels and lower EF were independent predictors of MACE.

Medical student's motivation regarding research. Initial theory for a realist review

Louis Van Maele¹, Jean Macq¹, Sophie Leconte²

¹Institute of Health and Society (IRSS), Université catholique de Louvain, Belgium

²Academic Centre of General Practice (CAMG), Faculty of Medicine, Université catholique de Louvain, Belgium

BACKGROUND & AIM:

Promoting research in family medicine is essential for the future of our young discipline. While most difficulties are common amongst all medical specialties (i.e. supervision or competence development), some are specific to family medicine and still need to be explored, especially regarding motivational aspects. This study aims to provide a theoretical framework that could describe the mechanisms involved in students' motivation to engage in research activities, in order to explain which intervention works for whom and under what circumstances.

METHOD:

Respecting methodological guidelines for realist review, an initial program theory of student motivation regarding research has been developed by consulting field experts and by exploring the literature for existing theories. Selected theories have been compiled using an integrative model for the theories of motivation.

RESULTS:

The initial program theory points out the different factors that could influence student's motivation regarding research, which include his perception of the value of a research activity, his competence to achieve it and the control he has on it. A need of understanding and accomplishment, the kind of scientific objectives and the value granted to research could determine the student's motivation during the process of scientific creation. This dynamic model could finally be influenced by the society, his scientific community, his work and family environment.

CONCLUSIONS:

The initial theory presented in this communication is the first step of a realist review. The next steps include a literature review using realist logic and focused on existing interventions in order to refine the initial theory, and 3 case studies to apply the theory to the particularities of family medicine.

The refined theory -which could be translated into Context-Mechanism-Outcome configurations ("in this context, that mechanism generates this outcome") or guides for program development- will help faculties promote research activities among family medicine students.

**Possibilities of knowledge circulation between neurodegenerative research and General Practice
(NEUROTRANS BMBF FZ 01GP1307)**

Markus Ludwig, Heinrich Herrmann¹, Astrid Eich Krohm¹, Bernt Peter Robra², Yvonne Marx¹, Julia Von Hintzenstern¹

¹Institute of General Practice and Family Medicine

²Institute of Social Medicine and Health Economics

Background & Aim

The NEUROTRANS project aims to build a sustainable knowledge transfer between GPs in Saxony-Anhalt and neuroscientists at the German Center of Neurodegenerative Disease Magdeburg (DZNE). The demographic challenge will dramatically increase the number of people with dementia over the next 30 years. GPs hold a key position in early detection of dementia because they are the first in the medical profession to realize changes in patients' behavior. However, very little is known how GPs detect and read those changes. Neuroscientists, on the other hand, are research focused and usually not connected with GPs' daily usual care. GPs make observations that can inform and contribute to research questions that would otherwise not be asked. At the same time, neuroscientists can inform GPs about the state of the research and how it might be helpful for their patients.

Method

The research design is based on a qualitative methodology by using semi-structured interviews and focus groups discussing case studies of patients with dementia. 36 GPs participated in qualitative interviews and different focus groups about their experiences in regards to early signs of dementia, tests and diagnosis, medications and counseling of patients and relatives. Qualitative interviews and observations of six leading neuroscientists provided insights into their work and their perspectives led to a professional exchange between both groups.

Results

Whereas GPs following a "life-world-perspective" are mostly concerned with the quality of life, neuroscientists based on a "biomedical-paradigm" conduct clinical research about brain functions and bio-markers with little attention paid to the daily situation of their research participants.

Conclusion

To foster a successful exchange between Neuroscientists and GPs joined research projects that focus on prevention and early detection of dementia promise to bridge the gap between the two groups and ultimately help to find solutions against dementia.

Medical students' attitude toward smoking in Poland & Kosovo

Sylwia Katarzyna Kalucka¹, Bashkim Gllareva²

¹The First Department of Family Medicine, Medical University, Poland, Lodz

²University of Prishtina' Hasan Prishtina' Faculty of Medicine in Kosovo.

Background and Aim. In 2030 about 8 million people will die because of smoking, and 80% of these deaths will take place in low and middle income countries. In Poland during last 25 years of political transformation were carried out preventive anti-smoking programs which decrease number smokers in society. Kosovo is at the beginning of the political transformation and we do not have complete data on the number of smokers in 2 million population. The aim of the study was an analysis of medical students' attitudes towards smoking in two different countries. Methods. A questionnaire on tobacco smoking was distributed among medical students of the last year at sixth year of their studies. Students who took part in this study, come from the Medical University of Lodz in Poland, English Foreign Division students (come from West European countries), and the Faculty of Medicine in Kosovo. Result. The study included 110 Polish medical students, 104 medical student from Kosovo, and 110 foreign medical student who study in Poland. In the Polish group were 8.2% active smokers, 70.9% non-smokers, 20.9 % ex-smokers. In the Kosovo group were 23.1% active smokers, 68.3% non-smokers, 8.6% ex-smokers. In the Foreign group were 18.6% active smokers, 63.7% non-smokers, 17.7% ex-smokers. There were statistically significant differences concerning two groups (Polish & Kosovo) of the subjects among active smokers, ex-smokers ($p < 0.0026$). There were no statistically significant differences between Kosovo & Foreign of the subjects among active smokers, ex-smokers, non-smokers ($p > 0.05$). Male students smoke cigarettes three times more often than female students ($p < 0.0001$). The average age of starting smoking among Kosovo students was 16,17 years, Polish students was 17,8 years, but for Foreign subjects was 18,07 years. Conclusions In XXI century medical students should have solid knowledge about smoking hazards, give up smoking in order to promote non-smoking among their patients in future.

Self-medication among cigarette smokers

Sylwia Kalucka

The First Department of Family Medicine, Medical University, Poland, Lodz

Background and Aim. It is estimated that in 2030 about 8 million people will die because of smoking, and 80% of these deaths will take place in low and middle income countries. Nowadays about 8 million Poles smoke cigarettes (30.3% of the total population aged 15 years and more). The aim of the study was analyze what methods smoking cessation using by chronic smokers cigarettes. Methods. The study randomly selected 323 people, who smoke cigarettes. The study group was divided into three subgroups according to number years of smoking. Among the participants were questions about the elements of use self- medication to quit smoking (chewing gum-Nicorette, nicotine patch, Tabex, Desmoksan, e-cigarette, tablets NiQuitin, motivation smoking cessation). Result. Among subjects (91 smokers) who smoke cigarettes only 10 years, chose the most often chewing gum (70), own motivation to quit smoking (79), e-cigarette (47). The group smokers (82 smokers) who smoke between 11 to 20 years, used the most often chewing gum (71), own motivation to quit smoking (50). This group smokers bought tablets NiQuitin, nicotine patch and Desmoksan the same often. The group smokers, who smoke cigarettes over 20 years, the most often use own motivation to smoking cessation than the other over-the-counter products. Over one year observation, only smokers, who had the highest motivation successful smoking cessation. Self-medication smokers, who bought over-the counter nicotine products after 3-4 weeks come back to smoking cigarettes. Conclusions. Self-medication among smokers willing to quit smoking nicotine replacement therapy for smoking cessation is not enough if a smoker does not have strong motivation.

Disease knowledge level of the uncontrolled type 2 diabetes patients who were admitted to Internal Medicine Clinic of Adana Research and Training Hospital

Hicri Sarıçam¹, Kenan Topal¹, Aylin Karsandık Akyol¹, Çiğdem Gereklioğlu²

¹Adana Numune Training and Research Hospital, Department of Family Medicine, Adana/Turkey

²Baskent University Medical Faculty, Department of Family Medicine, Ankara/Turkey

BACKGROUND: We aimed to investigate the factors influencing the disease knowledge level of the patients with uncontrolled type 2 diabetes who admit to Internal Medicine Clinic.

MATERIAL-METHOD: This cross-sectional study was conducted with 71 uncontrolled type 2 diabetes patients between February 1 and May 15, 2015. Demographic characteristics, educational level, coexisting chronic diseases, diabetes complications, spot plasma glucose on admission, HbA1c levels were recorded. The Knowledge, Attitude, and Practice (KAP) Questionnaire was administered. Two independent samples t-test and chi-square tests were used for statistical analysis.

RESULTS: Mean age was 54.6 ±11.07 years, 37 patients were male (52.1%). Thirty nine (54.9%) patients had at least one comorbidity, 31 (43.7%) had at least one complication. Mean plasma glucose was 327.2±144.8 mg/dL, mean HbA1c was 11.05 ± 2.03. While ratio of the patients with low knowledge level was 35.2% (n=25), ratio of the patients with satisfactory knowledge was 64.8% (n=46). The highest score was among the graduates of high school or university ($\chi^2=8.8$, $p=0.012$). A significant difference was not found between gender and KAP scores ($t=0.14$, $p=0.989$). Ratio of the patients with high KAP scores was greater among the patients with less higher HbA1c (7.0-8.4%), (100%, n=6) compared to the patients with moderate (8.5-10.4), (%70.4, n=19) and very high HbA1c (≥ 10.5), (%55.3, n=21), ($\chi^2=4.8$, $p=0.028$). The ratio of the patients with high KAP scores was greater among the patients with less higher plasma glucose (154-195 mg/dL), (90%, n=9) compared to the patients with moderate (196-252 mg/dL), (%77.8, n=7) and very high plasma glucose (≥ 253 mg/dL), (%57.7, n=30), ($\chi^2=4.49$, $p=0.034$).

CONCLUSION: Disease knowledge level increased, plasma glucose regulation improved as educational level increased. Better education and having sufficient knowledge about the disease would improve the success of follow up and treatment.

Assessment of screening tests in patients who were referred to pediatric endocrine outpatient clinic with suspicion of hypothyroidism

Süle Çalışkan¹, Kenan Topal¹, Çiğdem Gereklioğlu², Lena Türeyici¹, Yılmaz Kör³, Dilek Köse¹, Kayhan Süreyya Işgüzar¹

¹Adana Numune Training and Research Hospital, Department of Family Medicine, Adana/Turkey

²Baskent University Medical Faculty, Department of Family Medicine, Ankara/Turkey

³Adana Numune Training and Research Hospital, Department of Pediatrics, Adana/Turkey

BACKGROUND: Early diagnosis of congenital hypothyroidism is of great importance. We aimed to evaluate the screening tests done beginning from birth in the patients who were referred to Adana Research and Training Hospital in the context of newborn hypothyroidism screening program.

METHOD: This cross-sectional study was conducted with 424 cases between 1 June 2012 and 28 February 2015. TSH values tested with heel blood in the context of newborn hypothyroidism screening were compared with TSH values tested at Family Medicine Unit on day 7 and 14.

RESULTS: Of the patients, 241 (56.8%) were boys, the mean age of 19.7±8.4 days. Mean TSH of 375 newborns was 18.9±1.65 mIU/L and TSH was ≥ 5 mIU/L in 338 (90.1%), TSH was <5 mIU/L in 37 (9.9%). In Family Medicine Unit, mean TSH of 325 newborns was 26.4±2.07 mIU/L on day 7, TSH was ≥ 5 mIU/L in 323 (99.7%), TSH was <5 mIU/L in 1 (0.3%). On day 14, mean TSH of 172 newborns was 27.9±2.58 mIU/L and TSH was ≥ 5 mIU/L in 172 (100%). A statistically significant difference was found between TSH values tested at Family Medicine Unit and pediatric endocrine outpatient clinic ($r=0.594$, $p=0.00$ and $r=0.339$ and $p=0.00$). At pediatric endocrine outpatient clinic, mean TSH of 424 newborns was 18±30.3 mIU/L (min 0.19, max 150) TSH was ≥ 5 mIU/L pediatric endocrine

outpatient clinic in 216 (50.9%), TSH was <5 in 208 (49.1%). While sensitivity of screening test was 94% at birth, it was 98% on day 7 and 100% on day 14.

CONCLUSION: An ideal screening test should be inexpensive, non-invasive, clinically important, designed for the diseases which could lead to morbidity and mortality unless treated. Sensitivity of TSH screening tests done at Family Medicine Unit on day 7 and 14 was seen to be higher than test done at birth.

The Relationship between the Perception of Individual Workload and Life Satisfaction among Medical Residents

Rana Gundogan, Kubra Uyar, Ozge Berfu Gurbuz, Ediz Yildirim, Dilek Guldal

Department of Family Medicine, Dokuz Eylul University, Izmir, Turkey

INTRODUCTION:

Workload perceived by one has a close relationship with the life satisfaction one has. In this study the relationship between the perception of individual workload and life satisfaction of the residents, and factors affecting these two parameters were examined.

METHOD:

Residents who work in Dokuz Eylul University Medical Faculty were chosen for this cross-sectional analytic designed study. Three different questionnaires were used. A survey including demographic features as well as Individual Workload Perception Scale (IWPS) and The Satisfaction with Life Scale (SWLS) were applied to the residents. Data was processed with SPSS 15.0 package program. Besides descriptive statistics, for constant variables t test and ANOVA, and for categorical variables chi-square tests were applied.

RESULTS:

48.3% of the 236 participants were women, 55.9% of them were from clinics of internal medicine, and 38.6% of them were from surgical clinics. The mean age was 28.5 years, and mean of their residency duration was 27.3 months.

There wasn't any difference with their IWPS and SWLS points regarding their gender, number of children, profession duration, residency duration, choice of specialty or age.

As the number of weekly work time and monthly on-call time increased IWPS and SWLS decreased ($r=-0.294$; $p=0.000$ and $r=0.256$; $p=-0.000$), ($r=-0.268$; $p=0.000$ and $r=-0.199$; $p=0.002$). There was a positive correlation between IWPS and SWLS scales ($r=0.386$, $p=0.000$).

IWPS and SWLS points of the ones who thought that specialty would affect their social lives very negatively ($p=0.000$, $p=0.000$), their health negatively ($p=0.000$, $p=0.000$) and their cultural lives negatively were significantly low ($p=0.000$, $p=0.000$).

CONCLUSION:

There is a significant relationship between the perception of individual workload and life satisfaction, work time and negative thoughts about future, affect both parameters negatively.

Keywords: Workload, personal satisfaction, internship and residency

P-1134**Our hospital health workers and Patients beliefs and behaviors related to breast self-examination**

Ayşe Mıdık Özpak, Ismail Arslan, Fatma Begüm Tokatlıoğlu Özcan, Adil Çetin, Gökhan Dinçer, Oğuz Tekin

Department of Family Medicine, Ankara Training and Research Hospital

BACKGROUND and AIM: Early diagnosis and effective implementation of the correct method of breast cancer is easier to treat cancer by ensuring early detection. Important place to introduce a simple and cost-free technique with early breast self examination. In this study, health professionals and breast cancer patients admitted to various clinics and beliefs regarding breast self examination, aimed to determine the attitudes and behaviors.

METHOD: Working 86 health professionals working in Ankara Training and Research Hospital and was conducted with 114 patients admitted to various clinics. Questionnaire including socio-demographic characteristics of the collection of data and the Champion's Health Belief Model scale is used.

RESULTS: 200 people participated in the study mean age of 33.16(+/-8.6). Health workers who have 87.2% of the 31.3% were housewives makes 30.3% of other professional groups working breast self examination(BSE). 78% of participants BSE and they learn in various ways related to breast cancer has been shown to be 22% of the tray information. Knowledge of BSE have no knowledge while 69.2% of which is only 4.5% do BSE. BSE and the non participants confidence/self-efficacy statistically significant difference was detected between the subscale mean scores ($p < 0.05$).

CONCLUSIONS: Individuals perceptions about breast cancer and breast self examination determines the attitudes and behaviors of individuals. Self-efficacy/confidence and that when he attempts to make a behavior is the belief that individuals can succeed. People of breast cancer and to increase the knowledge about BSE and confidence/self to strengthen the effectiveness of sense to move them into action in this regard to improve the BSE frequency of application, will enable them to be more sensitive to early diagnosis. In the training of health workers to be given to this issue in particular places patients should be expanded by transferring this information to.

Keywords: breast self examination, breast cancer, early diagnosis.

P-1135**Burnout status of medical students and affecting risk factors**

Kubra Can, Oguz Yilmaz, Tugba Onat, Ediz Yildirim, Dilek Guldal

Department of Family Medicine, Dokuz Eylul University, Izmir, Turkey

Introduction

Burnout is a common syndrome seen in healthcare workers, particularly physicians who are exposed to a high level of stress at work. The health care providers are supposed to be at a high risk for developing burn-out syndrome, due to their involvement in emotional stressful situations and intense collaboration with patients in difficult conditions. This situation may start during pupilage. In our study it is aimed to evaluate the burnout status of medical faculty students and risk factors affecting this.

Methods

In this descriptive cross-sectional study, as a first step, factors affecting education processes are determined by brain storming with students. At the end a consensus of 13 item questionnaire is used as a 5-point Likert scale. Mentioned questionnaire and Maslach Burnout Inventory are applied to Class 4, 5 and 6 students of Dokuz Eylul Medical School. SPSS Version 16.0 is used for all analyses. Descriptive statistics, independent sample t-test, ANOVA and correlation analysis are used.

Results

The total mean point of MBI is 67.00 ± 6.79 and mean points of subscales of MBI are 24.45 ± 4.98 (emotional exhaustion), 16.67 ± 3.35 (depersonalization) and 25.85 ± 4.66 (low personal accomplishment). Among 247 students, Grade 5 students have lower burnout level compared to Grade 4 and Grade 6 students (respectively,

p=0.,039 and p=0.001). Social drinkers have lower burnout level compared to non drinkers (p=0.044). The ones studying for longer hours daily have higher level of burnout (p=0.000). The ones who think to leave medical faculty before graduation, who tried to use drugs, who don't have spare time for social life have higher level of burnout (p values respectively 0.037; 0.028; 0.002). There is a statistically significant, positive and weak correlation between MBI and our questionnaire (r=0.183, p=0.004).

Conclusion

The burnout level of medical students is over median and closely related with training environment.

Keywords: professional burnout, medical students, risk factors

⁵Department of Family Medicine, Faculty of Medicine, Duzce University, Duzce, Turkey

⁶Department of f Pharmacology, Duzce University, Medical School, Duzce, Turkey

AIM: We hypothesized that patients taking warfarin require frequent hospital follow-up and they are at higher risk for complications, so the incidence of depression and anxiety is higher in AF patients in the period of taking warfarin compared to the period of taking dabigatran.

METHODS: Fifty AF patients without valvular diseases under treatment of warfarin in whom a transition to dabigatran was planned were consecutively enrolled in this study and followed up prospectively between July 2013 and July 2014. All patients completed Beck Depression Inventory (BDI) and Hamilton Anxiety Scale (HAS) at the initiation of study and after six months after initiation of study. Of the subjects enrolled in the study, age, gender, smoking status and comorbidities, history of bleeding and transfusion were questioned.

RESULTS: A total of 50 subjects (28 woman; mean age 74.6±8.7 years) treated with warfarin in whom a transition to dabigatran were included. Table 1 shows basic demographic and clinical characteristics of study patients.

Table 2 gives comparison of mean values of BDS and HAS in patients before and after switching from warfarin to dabigatran. Basal mean value of BDS (24.4±11.9 vs 19.1±8.9, p<0.001) and HAS (18.7±12.5 vs 13.8±9.2, p<0.001) were significantly higher in subjects while they have used warfarin than while they were switched to dabigatran.

In categorical analysis, frequency of patients with depression (mild, moderate and severe) was significantly higher in period of warfarin use than after dabigatran transition (n= 24, 48% versus n=14, 28%, p=0.039).According to BDS categories, comparison of depression level between period of warfarin and dabigatran use was shown in Table 3.

CONCLUSION: Dabigatran decreases the score of BDS and HAS compared to warfarin in nonvalvular AF. These findings suggest that, dabigatran may increase quality of life and decrease morbidity and mortality due to reduction of anxiety and depression.

P-1137**" Turkish reliability and validity study of Physical activity barriers questionnaire "**

Gurcan Balik¹, Gamze Akyol¹, Dilek Guldal¹, Irfan Yurdabakan²

¹Department of Family Medicine, Dokuz Eylul University, Izmir, Turkey

²Department of Educational Sciences, Dokuz Eylul University, Izmir, Turkey

"INTRODUCTION:

Lack of exercise, which is a shared risk factor for many chronic diseases, comes fourth reason among the risk factors which cause death worldwide. The prevalence of physical inactivity changes between %28 and %81 worldwide. Besides prevalence of physical inactivity is between 87% with women and 77% with men in Turkey. At this context, it is important to examine the obstacles that the young adults in Turkey face which prevent them from having physical activities. However there isn't a scale in Turkish to use for this area. The aim of this study is to find out reliability and validity of "physical activity barriers questionnaire" which was developed by Suraya and his friends in Malaysia.

METHOD:

After a translation and retranslation, the scale was applied to 150 patients and their relatives who were between the ages of 18-45. The data was analyzed in SPSS 15 package program; for the validity of the scale Factor analysis, for the reliability of the scale Tukey test, Hotelling's T test, Split half and Cronbach α analyses were used.

RESULTS:

52% of the sample was male (n: 78) and 48% was female (n: 72). Minimum age was 18 (n: 2), maximum age was 45 (n: 2); the mean age was 32.7 and the median was 34. KMO Bartlett test was found to be 0.840, F value of the Tukey test was 18.5 (p=0.000) and the F value of Hotelling's T test was 9.6 (p=0.000). Split half Spearman-brown value was 0.909, Cronbach α value was 0.874 and when the questions were evaluated one by one; the minimum Cronbach α value was 0.863 and the maximum was 0.876.

CONCLUSION:

The analyses made show that "physical activity barriers questionnaire" is both very highly reliable and valid in Turkish."

P-1138**Knowledge and attitudes of patients about organ donation**

Gülay Şahin¹, Mustafa Kürşat Şahin², Füsün Aysin Artıran İğde¹, Mustafa Fevzi Dikici¹, Füsün Yarış¹

¹Department of Family Medicine, Ondokuz Mayıs University, Samsun, Turkey

²Canik Community Health Center, Samsun Turkey

Background & AIM: Organ transplantation is the most preferred treatment modality for end-stage organ diseases. The need for the transplants is higher than the availability. Prerequisites for the success of transplantation program include awareness and positive attitudes. This descriptive study was planned and applied to assess the knowledge and attitudes of patients who admitted to our clinic.

METHOD: Data were collected by the researcher, applying face-to face structured interview techniques with a questionnaire developed after a relevant literature review. Data were analyzed using SPSS 22.0 package program. In the analysis, frequency and percentage from descriptive criteria were used.

RESULTS: 109 patient participated our study. There were 68 (62.4%) female and 41 (37.6%) male. The average age of patient was 26.26 \pm 9.99 year. 68 (62.4%) of patients didn't want to donate organs. The decision to be an organ donor was influenced by relational ties, religious beliefs, cultural influences, family influences (15.6%), body integrity (15.6%), previous interactions with the health care system—medical mistrust, validity of brain death and fear of early organ retrieval (20.2%).

CONCLUSIONS: Patients have significant gaps in knowledge regarding the organ donation and transplantation system. Donation and transplantation education is necessary for community.

The relationship between self-rated health and periodic health examination in Samsun, Turkey

Mustafa Kürşat Şahin¹, Mustafa Fevzi Dikici²

¹Canik Community Health Center, Samsun, Turkey

²Department of Family Medicine, Ondokuz Mayıs University, Samsun, Turkey

AIM: To evaluate the relationship between demographic and medical status of the adults admitted to OMU School of Medicine Department of Family Medicine for the Periodic Health Examination between 2012- 2013 and their own "self-assessment of health".

METHOD: Total 274 Periodic Health Examination forms of the people admitted to department outpatient clinic between 01.01.2012-31.12.2013 were screened retrospectively. Data were processed using SPSS 22.0 for Windows. Data were evaluated as number and percentages, statistical significance was analyzed using t test, chi-square test and the Mann-Whitney U test. Statistical significance was considered at $p < 0.05$.

RESULTS: Of the 274 patients, 138 were women (50.4%) and 136 were men (49.6%). The mean age was 44.48 ± 15.72 years. Of the women, 95 (68.8%) and 70 of the men (51.5 %) had not exercised. In the patient group, body mass index of 159 (66.6%) was higher than 25 kg/m² and women had significantly higher body mass index than men. Total 75 (54.3%) women and 39 (28.7%) men had psychiatric disorders. Among these patients, 34 women (24.6%) and 17 men (12.5%) had a psychiatric drug use. history of psychiatric illness. Psychiatric illness history ($p < 0.001$) and psychiatric drug use ($p: 0.010$) was significantly higher in women than in men. Of the 90 women over 40 years, 66 (73.3%) had mammography. One patient was diagnosed with breast cancer. Of the participants, 113 (41.3%) stated that their general health status was poor. Women's self-assessment of health was significantly worse.

CONCLUSION: More than half of the participants had not exercised and were overweight or obese. As a result of cancer screening, a patient with breast cancer was detected. More than half of women had a psychiatric illness while one in four of the men had. Self-assessment of women and people with psychiatric disorders was significantly worse.

What patients want from their family physician?

Mustafa Kürşat Şahin¹, Gülay Şahin², Mustafa Fevzi Dikici², Füsün Aysin Artiran Iğde², Füsün Yarış²

¹Canik Community Health Center, Samsun, Turkey

²Department of Family Medicine, Ondokuz Mayıs University, Samsun, Turkey

Background &AIM: The public wants and is satisfied by care provided within a patient-physician relationship based on understanding, honesty, and trust. If the Turkey health care system is ever to become patient-centered, it must be designed to support these values and sustain, rather than fracture, the relationships people have with their primary physician. We aimed to evaluate the expectations of the patient's from family physician.

METHOD: The data were collected from 126 patients between 1st -31st March 2014 who admitted to family medicine clinic. In this study, by reading the relevant literature and requirement on the research, we prepared to questionnaire. Data were analyzed using SPSS 22.0 package program. In the analysis, frequency and percentage from descriptive criteria were used.

RESULTS: There were 65 (51.6%) male and 61 (48.4%) female patients. The average age of participants was $32,23 \pm 12,62$ year. Patients wanted who was nonjudgmental(120/126), understanding (126/126), and supportive(126/126); honest and direct; acts as partner in maintaining health (112/126); listens effectively (121/126); and attends to patients' emotional and physical health (111/126)

CONCLUSIONS: Even though patients and physicians are frustrated by the healthcare system, the research showed that patients seem to want the same things WONCA's criteria.

Views And Opinions of the Students of Dumlupınar University about Family Medicine

Yasemin Korkut, Emre Ayaz

Department of Family Medicine, Dumlupınar University, Kütahya, Turkey

Aim

The aim of this research is to find out the thoughts of the university students, studying at Dumlupınar University, about family medicine practice and to evaluate their point of views.

Materials and Methods

Our research is a cross sectional survey on university students between the ages of 19-25 studying at Dumlupınar University in Kutahya. It was conducted between April-May in 2015. The questionnaire was completed by the participants who were selected by random sampling.

Results

The average age of the 107 students participating the study was 21.8 ± 1.4. When the participants were questioned about their level of knowledge about family medicine; 39% of them was at high level and 61% of them was at the medium or low level. When their satisfaction on the applied family medicine was inquired; 69% of them were not satisfied. 24% of them were unsatisfied because of the inadequate number of family physicians and the 17% was because of the lack of time devoted to the patients. Only 4.2% of the students thought that the application of the family medicine was very good.

Conclusions

As a result of our study, it was observed that practicing of family medicine is not known by the University students and probably for this reason when they go to an outpatient clinic they don't have a high level expectation. Consequently, informing the youngs about the the system of family medicine which has been adopted for almost five years need to be developed.

The World and you: An evaluation of Twitter use at a recent international family medicine conference

Kyle Hoedebecke¹, Andrea De Angulo²

¹Wonca Polaris, USA

²Waynakay, Colombia

BACKGROUND: The use of social media within medicine has increased every year. Yet, few publications exist describing its daily use or benefit to the medical community across the world. No peer-reviewed literature exists identifying the use of Twitter within WONCA or within Latin America.

METHODS: A literature search using PubMed resulted in only 13 results using "Twitter" and "Family Medicine." Furthermore, only one of these described the use of Twitter at a Family Medicine conference - the 2013 Society of Teachers of Family Medicine conference in the United States. Using the online tool Sympur, the authors have evaluated the Twitter use at the recent WONCA Iberoamerican Conference in Montevideo, Uruguay where the hashtags #4cwic and #waynakay2015 were used. The results were compared to other conferences.

RESULTS: The hashtag #4cwic had 4129 tweets from 551 users: 36.1% of the conference participants. The hashtag #waynakay2015 had 387 tweets from 72 users: 45% of the preconference participants. The top ten users were responsible for 69.2% of the activity of #waynakay2015 and 58.6% of that of #4cwic.

Conclusions: This is the first study to evaluate Twitter use in Iberoamerica as well as in a WONCA conference and has allowed for the evaluation of overall activity, major influencers, and for potential future uses within medicine for both academic and social purposes. Continued research is needed to further develop and identify uses of sites like Twitter or Facebook.

⁴Pınar Yıldız: Eskişehir Osmangazi University Faculty of Medicine Department of Internal Medicine, Eskişehir, Turkey

⁵Seda Güler: Eskişehir Osmangazi University Faculty of Medicine Department of Family Medicine, Eskişehir, Turkey

⁶Muzaffer Bilgin: Eskişehir Osmangazi University, Faculty of Medicine, Department of Biostatistics and Medical Informatics, Eskişehir, Turkey

AIM: Our aim was to evaluate the potential effect of 25 (OH) levels on HbA1C levels in a population which were 65 years and older with type 2 diabetes mellitus (DM).

RESULTS: A total of 106 people were participated in the study (36 men and 65 women). The mean of vitamin D (VD) values is $18,65 \pm 14.17$ ng/ml and mean of HbA1c levels is 7.45 ± 1.42 . Vitamin D insufficiency was defined as serum 25-hydroxyvitamin D level of <30 ng/ml. The target value for HbA1c levels was accepted as below %7. Vitamin D deficiency was found in %80.0 of our patients. We found an inverse correlation between HbA1c and vitamin D levels ($p=0.001$). HbA1C levels were significantly high in the group with 25OH VD deficiency (7.62 ± 1.47 vs 6.77 ± 0.92 ; $p=0.011$). In 25OH VD deficient group; rate of having target HbA1C values was significantly low (% 41.2 vs %65; $p=0.094$).

DISCUSSION: VD deficiency is more common in the elderly population. VD deficiency seems to be a negative factor affecting the control of type 2 DM. This subject should be evaluated by different studies.

Keywords: Vitamin D, HbA1C, Elderly Population, Type 2 Diabetes Mellitus

P-1144**Inappropriate Nonsteroidal Anti-Inflammatory Drug Use Among Elderly According To STOPP Criteria**

Gamze Akyol, İlke Ekim Yardım, Candan Kendir Çopurlar, Tuğba Onat, Tolga Günvar, Dilek Güldal

Department of Family Medicine, Dokuz Eylül University, Izmir, Turkey

BACKGROUND & AIM:

Inappropriate nonsteroidal anti-inflammatory drug (NSAID) use among persons ≥ 65 years of age is a common health problem worldwide, and causes various preventable adverse effects. Several studies have shown that inappropriate NSAID use (INU) rates are between 11.2% and 20.1% among older adults and their knowledge of NSAIDs is considerably low. Our objective is to determine the frequency of INU among elderly and to investigate related factors.

METHODS:

A cross-sectional study was conducted in 5 different Family Health Centers in Balçova district of Izmir. Questionnaires which included demographic data, questions regarding adverse effects and questions related to STOPP criteria for NSAIDs were conducted by the researchers with face-to-face interview method. All data analyses were performed using IBM SPSS software (version 22.0).

RESULTS:

412 participants with mean age of 71.57 (SD: ± 5.92) were included, 223 (54.1%) of them were women. 225 (%54.6) of all participants reported that they prefer to use NSAIDs for their pain. 61 (14.8%) participants had INU when "moderate/severe hypertension (MSH)" was excluded as a criteria for INU; this number went up to 90 (21.8%) when MSH was included. Age, sex, educational level and knowledge about side effects except for "allergy" ($p<0.05$) and "stomach-ache" ($p=0.001$) were not significantly related to INU. To have a specific preference of a NSAID for pain ($p<0.05$) and using painkillers / NSAIDs in the last week ($p<0.05$ / $p<0.001$; respectively) were significantly related to INU.

CONCLUSION:

Under the guidance of STOPP criteria, this study highlights inappropriate NSAID use in Izmir, Turkey.

Keywords: nonsteroidal anti-inflammatory drugs, NSAIDs, inappropriate drug use, STOPP criteria, elderly, knowledge

P-1145**Investigation Of Blood Biomarkers And Other Risk Factors Associated With Mild Cognitive Impairment Among Turkish Type 2 Diabetic Patients**

Aclan Ozder, Zeyneb Irem Yuksel Salduz, Mesut Bilginc, Zeynep Bakir

Department of Family Medicine, Bezmi Alem Vakif University, Istanbul, Turkey

Background & AIM: Diabetes mellitus is a common metabolic diseases associated with an increased risk of mild cognitive impairment (MCI) and dementia (1,2). The aim of this study was to determine the relationship between some risk factors and cognitive function in patients with type 2 diabetes mellitus (Type 2 DM).

METHOD: A total of 101 adults with Type 2 DM were included to study. The exclusion criteria were diagnosed depression or dementia. The Montreal Cognitive Assessment (MoCA) and the Standardized Mini-Mental State Examination (SMMSE) were used for cognitive function assessment. Functional information on daily activities was collected using Katz Basic Activities of Daily Living (BADL) and Lawton Instrumental Activities of Daily Living (IADL) questionnaires. Fasting blood glucose (FBG), Urea, Blood urea nitrogen (BUN), Creatinine, C-reactive protein (CRP), High-density lipoprotein (HDL), Low-density lipoprotein (LDL), Total cholesterol (TC), Triglyceride (TG), Alanine aminotransferase (ALT) and Glycated hemoglobin (HbA1c) levels were measured in all subjects.

RESULTS: The prevalence of MCI in diabetic patients was 78.2%. Type 2 diabetic patients with MCI were older and 56 (70.8%) subjects were female. The background characteristic of MCI in diabetic patients included lower education level and monthly income, longer duration of diabetes, higher rate of current smoking and use of anti-hypertensive drugs, also higher serum level of HDL (Table 1).

CONCLUSIONS: According to our findings, MCI in type 2 DM patients has a high prevalence, especially influenced by demographic variables. Early detection and appropriate management of diabetes in primer health care seems to reduce the risk of MCI.

What we can change in young people health?

Maria Malarska¹, Paulina Pachniak¹, Michał Podgórski², Michał Matyjaszczyk¹, Przemysław Kardas¹

¹Department of Family Medicine, Medical University of Lodz, Lodz, Poland

²Human Anatomy Collegium Anatomicum, Medical University of Lodz, Lodz, Poland

What we can change in young people health?

Self-examination in Poland is still the taboo subject. Young people want to know but they don't know where they can find this information. In our study we talk with almost 1500 people and sent our questionnaire to 500 girls and boys. Conversation with them open our eyes to the deep problem which is controlling their body by themselves. Two very popular cancers- testicle and breast, are not well "popular" subject to talk. Young men are afraid to talk to their doctors and family about sexual health and as a result they don't know how to properly do self-examination. Similar situation is with girls, if they didn't start examination now, they wouldn't do it when they have to. Also young people want to examine their partners, but they don't have a clue how to do it. What is more the big problem is also with cytology. Women under 25 years are afraid of this examination and they don't know what this test can change.

Our study shows that there is a lot to change in young people knowledge. It is our duty to protect them.

Knowledge, attitudes and barriers of primary care physicians towards water pipe smoking cessation

Maya Romani¹, Manar Shalak², Jumana Antoun¹

¹American University of Beirut, Beirut, Lebanon

²Yas health care center, Abu Dhabi, UAE

Background and AIM: Five million people die yearly from tobacco smoking and the number is expected to double in the following 20 to 30 years. Water pipe smoking is a new emerging epidemic that warrants serious movements against its spread because it is associated with similar if not even more health negative effects than cigarettes smoking. However, the paucity of studies targeting water pipe smoking and the wide acceptance of the society of water pipe smoking made us hypothesized that physicians might not be well equipped for proper counseling towards cessation of water pipe smoking. Thus this study aims to study the attitudes and knowledge of primary care practitioners towards water pipe smoking and the barriers to its cessation.

METHODS: This is a cross-sectional study using an anonymous survey among participants of an annual conference for family medicine in Lebanon.

RESULTS: 105 primary care practitioners (PCP) were surveyed. with 58% response rate. Only 38.1% of the physicians think similar techniques are used for cessation both cigarette and water pipe smoking. Similarly, 30.5% of the physicians think that nicotine replacement therapy works in water pipe smoking cessation. There was significant difference between the percentage of physicians who counsel for cigarette and those who counsel for water pipe smoking cessation ($p=0.005$) where 30% of the physicians tend to counsel against cigarette more than water pipe smoking. The major perceived barriers for waterpipe smoking cessation were the patients' compliance, the unavailability of referring program and the patients lack of awareness about waterpipe

CONCLUSION: This study shows a difference in the attitude and behavior of PCP towards cigarette and water pipe smoking. Moreover, there is lack of knowledge about water pipe smoking cessation techniques. Therefore, there is a great room for continued medical education to PCP in their private practice to improve their knowledge

Barriers to visiting a Family Physician: a nation based survey in Lebanon

Manar Hamid Shalak¹, Maya Romani², Joumana Antoun²

¹Yas Health care

²American University of Beirut medical center

Background and AIM: Primary care improves health and “people receiving care from primary care physicians are healthier”. Although evidence shows that primary care offers health equity, positive health outcomes and cost-effective care, it is still not the key element of all health care systems worldwide. In many European countries, general practice is the cornerstone of healthcare systems. Recently in the United States they are putting emphasis on primary care. However, the Middle East health care systems are still based on free market. Our aim is to assess the patient’s knowledge, attitude and practice regarding family medicine in Lebanon and to identify barriers for not visiting a family physician in a free market health care system.

METHODS: We conducted a nation based, anonymous phone survey among a sample of Lebanese population.

373 citizens were randomly chosen, 60 from each one of the six Lebanese regions and enrolled in the study

RESULTS: the study showed that 72.4% of the sample did not understand the scope of practice of family medicine, even though 63% had heard the term 'family medicine'. The perception of the respondents of the scope of family medicine differed among the various services of family practice. A family physician could treat all family members (93%), common diseases (80%), deal with prevention (86%) and chronic diseases (80%). However, family

physicians were not qualified to do pap smears(70%), insert an intrauterine device(74%) or perform a normal vaginal delivery(62%). 70% of those surveyed had a regular doctor. The main identified barriers were the lack of awareness about family medicine in addition to the absence of a nearby or accessible family doctor.

CONCLUSION: Family practice in Lebanon is undervalued; actions should be taken to focus on population education. Without proper official plans from healthcare policy makers, family practice is unlikely to reach its mission.

Vitamin D Deficiency in Adults

Turan Set, Elif Altunbaş Ateş, Rahman Kuri, Ceyhun Yurtsever

Department of Family Medicine, Karadeniz Technical University Medical Faculty, Trabzon, Turkey

BACKGROUND & AIM: Vitamin D is the steroid hormone involved in mineral ion homeostasis regulation. It plays an important role in bone health maintenance and neuromuscular functioning. Vitamin D deficiency in adults has been associated with muscle weakness and an increased risk of falling. In this study, we aimed to assess prevalence of the vitamin D deficiency in adults at our clinic.

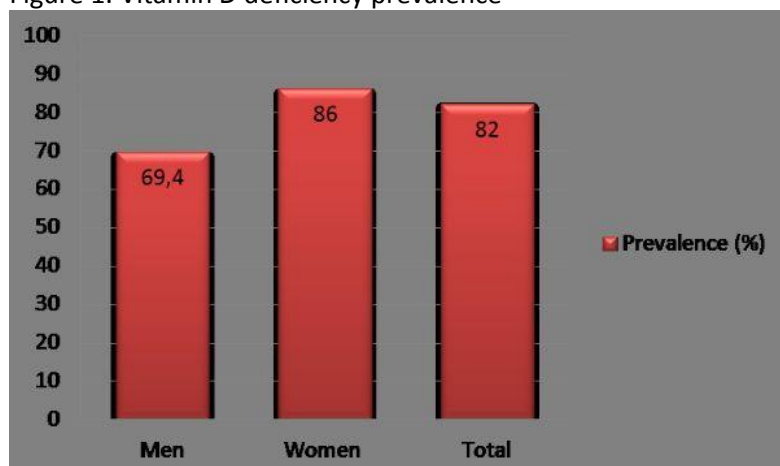

METHOD: This retrospective study was carried out between February 2014 and January 2015 in family medicine clinic. In the study, we included the data of 150 patients who are 18 years and over. Patients were divided into two groups. Group 1: Patients with vitamin D deficiency [25(OH) vitamin D levels <20 ng/mL], Group 2: Patients who have not vitamin D deficiency [25(OH) vitamin D levels >20 ng/mL]. Sociodemographic characteristics and serum 25(OH) vitamin D levels were recorded. Data were analyzed using SPSS.

RESULTS: The average age of patients was 35.4±12.8 years. There was no significant difference between the mean age of men and women (p=0.108). In this study, 76% (n=114) of patients were female. Average vitamin D levels were 16.4±8.9 ng/ml in men and 12.8±8.8 ng/ml in women (p=0.033). Vitamin D deficiency prevalence were found 82%. This ratio were found 69.4% (n=25) in men and 86% (n=98) in women (p=0.024).

CONCLUSIONS: Our study found that vitamin D deficiency in four out of every five adults. This deficiency was significantly higher in women than men. These findings may be associated with climatic conditions, dietary habits and inadequate utilization from sunlight. The most common cause of vitamin D deficiency are insufficient encounter with sunlight. The scope of preventive health services of family physicians for the prevention of vitamin D deficiency in adults will be useful to give advice about the utilization from sunlight and diet to individuals.

Prenatal Care Status of Mothers Admitting to a Newborn Clinic

Emrah Ersoy, Esra Saatci

Department of Family Medicine, Cukurova Universty, Adana, Turkey

Background and AIM: Prenatal care is a type of preventive healthcare with the goal of providing regular examinations to prevent potential health problems throughout the course of the pregnancy while promoting healthy lifestyles that benefit both mother and child.

METHODS: Sixty six mothers admitting consecutively to the Newborn Outpatient Clinic of Cukurova University Hospital in May 2015 completed a sociodemographic and Prenatal Care Questionnaire. Response rate was 100%. Data was installed and analyzed using SPSS statistical pocket program version 20.

RESULTS: All mothers stated that they had prenatal care. Of mothers, 31.3% (n=21) was in the 26-30-age group, 61% (n=41) were housewives, 34.3% (n=23) were high school graduates, and 46.3% (n=31) were married and 50.7% (n=34) had their first pregnancy in the 21-25-age group, 17.9% (n=12) of mothers had previous abortions and 11.4% (n=6) had dilatation and curettage. No stillbirths were declared. Two mothers had disabled older children. More than half of the mothers (53.8%, n=36) stated that they did not use any contraceptive methods and 85% (n=57) of pregnancies were intended. Of mothers, 83.6% (n=56) initiated prenatal care in the second month of pregnancy, 73.1% (n=49) had no health problem during pregnancy. There was a significant relationship between the time of onset for prenatal care and the health problems ($p=0.0001$). Of mothers receiving nutritional consultation, 61.2% (n=41) stated that they changed their nutritional behavior ($p=0.0001$), 92% (n=62) had tetanus vaccination and iron, calcium, and vitamin supplementation in Family Health Centers. Seven mothers quitted smoking during their pregnancy.

CONCLUSION: Family physicians have an essential role in providing integrated prenatal care, including evidence-based screening, counseling, medical care, and psychosocial support.

Bronchiectasis, severity ranges in Primary Health Care

Amparo Hervás Docón¹, Silvia Álvarez Álvarez², Núria Sánchez Ruano¹, Laia Gené Huguet¹, Xavier Flor Escriche², Elisenda Sant Arderiu³, Marta Navarro González¹

¹cap comte borrell, barcelona, spain

²cap chafarinas, barcelona, spain

³cap casanovas, barcelona, spain

Justification

Bronchiectasis not due to cystic fibrosis is characterized radiologically by permanent dilation of the bronchi, and clinically by a syndrome of cough, sputum production and recurrent respiratory infections. The prevalence of bronchiectasis is not precisely known and has been historically underestimated. International data show an increase in the prevalence of bronchiectasis over recent years. The impact on healthcare systems is substantial. Bronchiectasis has a clear attributable mortality. Bronchiectasis is a heterogeneous disease with a highly variable impact on patients. Severity ranges from patients without daily symptoms who have infrequent exacerbations, to patients requiring lung transplantation. Rate of lung function decline is highly variable and is associated with P.Aeruginosa colonization and severe exacerbations. Often the patient with bronchiectasis is visited in primary health care when it presents an exacerbation; therefore patients should receive treatment appropriate to their stage and severity of disease.

Recently, the European bronchiectasis network described the first clinical prediction tool for hospital admissions and mortality in bronchiectasis, the Bronchiectasis Severity Index(BSI).

Content

We propose to test BSI to all patients who are diagnosed of bronchiectasis in our computer clinical history. The

following variables will be evaluated: age, body mass index ($\text{kg}\cdot\text{m}^{-2}$), FEV1(%) predicted (forced expiratory volume in 1 s), hospital admissions in the past 2 years, exacerbation frequency in the past 12 months, MRC dyspnoea score(Medical Research Council), bacterial colonization (Pseudomonas aeruginosa, other potentially pathogenic microorganisms, none), radiological severity (≥ 3 lobes involved or cystic bronchiectasis, <3 lobes involved). Then we will have a different rate: 0–4 points: low risk of hospitalization and mortality; 5–8 points: moderate risk; ≥ 9 points: high risk.

In this way we will have a description of gravity range of our patients with bronchiectasis, which will allow us to give an appropriate treatment in order to the stage and severity of this disease.

Investigation Of Socioeconomic Status Evaluation Grouping Criterias In Medical Studies

Ali Ümit Geçkil, Altuğ Kut, Funda Salgür, Gökhan Eminsoy, Fisun Sözen, Yasemin Çetinel
Department of Family Medicine, Baskent University, Ankara

Background & Aim

Socioeconomy is a concept that covers social and economical structures of society in addition to the relationship among them. In general socioeconomic status (SES) can be defined as a set of various and up-to-date criterions which reflect not only individuals' but also families' income, educational status, and employment. In order to evaluate results of medical studies in the right way, both socioeconomic indicators and the researches should be properly selected and designed.

METHOD:

This study is designed as a cross-sectional observational survey. Articles written between years 2004-2014 were scanned among Turkish Medical Database of ULAKBİM. SES evaluation criterias were questioned in those articles. In this context, articles having keywords "Socioeconomic, sociodemographic, sociocultural, demographic" in its header or the text were included the study.

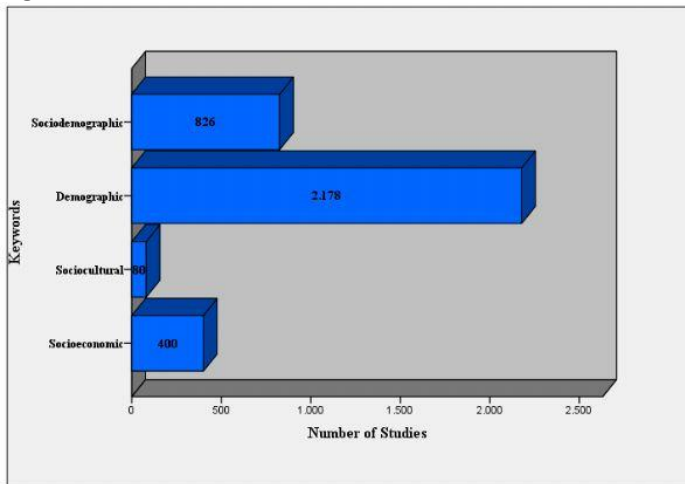

Data were analyzed using SPSS v21.0 software. For descriptive statistics mean±SD, minimum-maximum levels and percentages were used; continuous variables were analyzed using t- test and categorical variables using Chi-square tests. P values <0.05 were accepted as statistically significant.

RESULTS: 80 articles were analyzed so far out of 3342 selected articles. 25% of them were written in English (n=20). 32.5% were published in international journals (n=26). Most frequently used criterias were age, gender, education and household income. 63.75% of them made a right association between the article's main subject and socioeconomic parameters (n=51).

CONCLUSION: This research that still goes on. So far articles show us that the socioeconomic criterias are widely divergent and not properly used to form the article structure. In other words the association between socioeconomic criterias and results among 36.25% of the articles were not well associated.

Expressive and Procedural touch in clinical consultations in the United Arab Emirates

Usman Ghani Lashari

United Arab Emirates University

Background

Verbal and non-verbal communication skills are essential for successful doctor-patient relationship and integral part of day to day clinical consultations. Touch is an important part of non-verbal communications. This study investigates use of touch of clinical consultations in UAE. No such data is available in UAE. Touch has been divided into procedural (related to performing a procedure) and expressive (unrelated to a procedure).

Aim

This study investigates doctors and patients perceptions and experiences in clinical consultations.

Design

Qualitative study in city of Al-Ain, UAE.

Method

Participating doctors and patients were asked to fill in a questionnaire and informal interviews. Data was subjected to comparative analysis

Results

305 patients and 21 doctors participated in the study. 51% of the patient participants were Emiratis and 49% were expats residing in Al Ain. 23% of doctors were Emiratis and 77% were expat physicians. Age range 18-67 years. 52% patients rated expressive touch as a fair to excellent form of non-verbal communication and 48% of the patients rated it as a poor. Only 11% of the patients were touched expressively by their physician in the past 12 months.

96% physicians acknowledged expressive touch as fair to excellent form of communication. There were clear gender preferences among the doctors and the patients as being touched by the same gender was felt as more appropriate.

Preferred areas for touching included hands, arms, shoulders and head. Majority of doctors used expressive touch in consultations relating to breaking bad news, bereavement, showing compassion and trust.

CONCLUSIONS:

Expressive and procedural touch are an important part of non-verbal communication between patients and doctors. Mixed results were obtained relating to its current use in a relatively conservative society in UAE. Increased education of use of expressive touch would probably enhance doctor patient relationship and probably improve clinical outcomes.

The attitudes of family medicine residents in Ankara regarding to coagulation tests, anticoagulant treatment and monitoring

Iskender Bülbül¹, Irfan Şencan², Ismail Kasım², Adem Bahadır³, Ömer Akca⁴, Turgay Albayrak⁵, Rabia Kahveci², Adem Özkara²

¹Guzelyurt County Hospital, Aksaray, Turkey

²Ankara Numue Education and Research Hospital, Ankara, Turkey

³Kalkandere County Hospital, Rize, Turkey

⁴Kayseri Education and Research Hospital, Kayseri, Turkey

⁵Cigdemtepe ASM, Yenimahalle, Ankara, Turkey

Background & Aim

Failure in prevention of arterial and venous thrombosis or inability to manage of thrombosis treatment is a clinical condition which is morbidity and mortality is very high. Because of family medicine is first point of contact in health care system every family medicine specialist should know Monitoring of coagulation tests, current anticoagulant therapy and knowledge of the complications that can occur during treatment and situations that can impair these tests. These has to be essential knowledge and skills of family medicine specialists. The aim of our study is to evaluate the knowledge and attitudes of the family medicine residents in Ankara about anticoagulant therapy and its' monitoring.

Method

Observational and cross-sectional survey was designed. Configured 21 question survey was created after pilot study. The study executed among 216 family medicine residents from university hospital and educational and research hospitals in Ankara. 199 resident agreed to participate study and 143 of them who answered questions fully included to study. Data were evaluated in SPSS program using chi-square, likelihood ratio by chi-square or Fisher's exact chi-square.

Results

The majority of the research participants consisted of young physicians, who have not completed 10 years in their medical profession. The residents stated that only 8.4% of them attended a training on anticoagulant treatment and follow-up. We found that participants who attended training have more accurate answers to questions which intended to measure awareness and knowledge. The correct answer rates of the group that we call young physicians was higher.

Conclusions

Our findings revealed that the awareness about anticoagulant therapy and monitoring are low and there is a need for education. We need studies to identify and education plans on subjects for family medicine residents in order to improve their awareness and better equipped family physicians.

Internet Addiction And Related Factors In a University Sample

Tuğçe Refika Turan, Fisun Sözen, Ali Ümit Geçkil, Sinem Aydemir, Rengin Erdal

Department of Family Medicine, Baskent University, Ankara, Turkey

Background and AIM:

Internet addiction can be defined as excessive and also uncontrolled use of internet which results in weak academic and professional performance, relationship dispute, sleep disorder and psychiatric symptoms. Several scales have been developed to assess internet addiction. Young Internet Addiction Scale is among one of the most widely used scales for this purpose. In European based trials, rates of internet addiction were between 1-9%. The aim of this research is to figure out internet addiction prevalence and factors related among a population of university students.

MATERIALS-METHOD:

This study is planned as a cross-sectional survey including a 27 item questionnaire applied to university students. Besides Young Internet Addiction scale is added to the questionnaire. The sample size is calculated as 390 university students. So far we have fulfilled results of 100 volunteers.

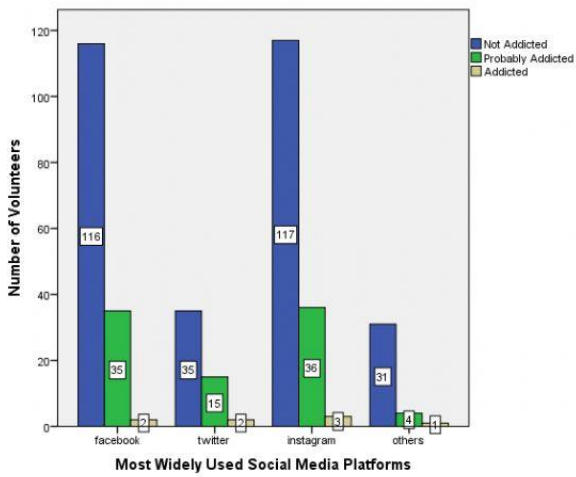

RESULTS:

Mean age of 100 participants was $20,66 \pm 1,8$. 70% were female (n=70) and 56% (n=56) of participants were students in Faculty of Social Sciences. Preferred internet connection locations were 27% home, 8% school and 65% mobile (cell phones etc). 87% of participants preferred using mobile phones as a method to connect the internet (n=87). We also found that there is a correlation between Young scores and duration of social media use. According to Young Internet Addiction Scale 67% were not addicted, 29% were probably addicted and 4% were addicted.

DISCUSSION:

Results of 100 participants have been processed. We expect to define internet addiction prevalence and related direct and indirect factors affecting this health issue by the help of this survey. Our findings were coherent with general prevalence worldwide. It can be stated that social media is the major use of internet among university population nowadays.

The comparative effects of a Buddhist meditation retreat and vacation on mindfulness and measures of well-being

Otto Pichlhöfer¹, Adrienne Chang², Gerhard Blasche¹

¹Medical University of Vienna

²Miami University, Ohio

***BACKGROUND:** * Recovery from work through respite and vacations is necessary to maintain well-being and health and is essential to avoid a variety of negative health outcomes like burnout, chronic fatigue, psychosomatic diseases and longer sick-leave. To identify activities enhancing the duration of recovery effects are of interest.

***METHODS:** * A sample of Europeans and North Americans was invited to participate in the study. A questionnaire was electronically administered 10 days prior, 10 days after and 66 days after the retreat/vacation. Respondents in the meditation retreat group (n=60) were compared to vacation with meditation (n=40) and vacation without meditation (n=26). Measures were “act with awareness” (10 items) and “accept without judgment” (9 items), the “fatigue assessment scale” (10 items), the “perceived stress scale” (10 items) and the “WHO-5 Well-being Index” (5 items). First, the retreat was compared with those individuals taking a vacation without meditating during vacation. Second, the retreat was compared with those individuals taking a vacation in which they did meditated. Within person contrast were calculated comparing assessment 1 & 2 as well as assessment 1 & 3.

***RESULTS:** * The total group time effect was significant for all variables between assessment times 1 & 2 and 1 & 3. The within-subject contrasts of retreat versus vacation without meditation showed a significant difference for act with awareness and accept without judgment at both time intervals and for perceived stress and emotional well being at time 3.

***DISCUSSION:** * Participation in a residential meditation retreat of 1-week or longer and leisure vacation with meditation, leads to significant stress reduction and increased mindfulness compared to leisure vacation alone. Our findings suggest benefits of mindfulness meditation on retreats and mindfulness meditation on vacation over vacation alone in promoting a more enduring, long-lasting, resilient response to daily stressors and improved, sustained psychological well-being.

Quality of life of dyspepsia patients who were admitted to Family Medicine Clinic of Adana Numune Research and Training Hospital

Dilek Köse¹, Kenan Topal¹, Çiğdem Gereklioğlu², Sait Yıldırım¹, Kayhan Süreyya Işgüzar¹, Gizem Erdoğan¹

¹Adana Numune Training and Research Hospital, Department of Family Medicine, Adana/Turkey

²Baskent University Medical Faculty, Department of Family Medicine, Ankara/Turkey

BACKGROUND: Dyspepsia is defined as a recurrent and persistent disturbance composed of distention and early satiety in the upper part of the abdomen and epigastrium. Its prevalence is between 25-40%. We aimed to evaluate the quality of life of the dyspepsia patients.

METHOD: The study included 66 dyspepsia patients. A structured questionnaire form inquiring the sociodemographic data, nutritional habits was applied and quality of life was evaluated with WHOQOL-BREF quality of life scale. Comparisons between groups were done with independent two-sample t-test.

RESULTS: Mean age was 37.58±12.7 years. Of the patients, 53.0% (n=35) were female, 68.2% (n=45) were married, 31.8% (n=21) were graduates of elementary school, 30.3% (n=20) were graduates of high school, 69.7% (n=46) had less than 2 children, 30.3% (n=20) were working at private sector, 77.3% (n=51) were living at city center. Mean WHOQOL-BREF score was 16.0± 2.03. When the highly educated (53%, n=35) and poorly educated (47%, n=31) groups were compared with regard to physical and psychological health domains of the scale, a statistically significant difference was not detected between groups (t= -0.029, p=0.97 and t= -0.922, p=0.36, respectively). There was a statistically significant association between groups in social relationships and environmental domains. A significant difference was detected between WHOQOL-BREF total score of the groups (t = -2.28, p=0.026).

CONCLUSION: Sufficient approach of the family physicians is of great importance for dyspepsia. Biopsychosocial approach, the main principle of family medicine, addresses not only the diseases but also their influences on quality of life. Our study indicated that dyspepsia leads to an impairment in total score and especially social relationships and environmental domains of WHOQOL-BREF quality of life scale in poorly educated dyspepsia patients.

³Department of Family Medicine, Kurtul Family Health Center, Kahramanmaraş, Turkey

⁴Kahramanmaraş Branch of the Council of Forensic Medicine, Kahramanmaraş, Turkey

⁵Department of Microbiology, Necip Fazil City Hospital Kahramanmaraş, Turkey

BACKGROUND: This study aimed to discuss hepatitis prevalence and hepatitis genotypes among prisoners as a specific group.

METHODS: The study was endorsed by Kahramanmaraş Sutçu Imam University Medical Faculty Ethic Committee (date: 02.06. 2014, number 07) and was conducted with the permission of the Kahramanmaraş Public Prosecutor. Two hundred sixty-six patients who have been convicted of several crimes such as robbery, sexual abuse, assault, violence, and substance selling and abuse were included in the current study.

RESULTS: Of the 266 patients, 89.5% were male, 10.5% were female, and the mean age was 31.21± 8.99 years. Risk factors were detected in 27.4% of the patients. Out of 73 cases who had risk factors, a history of intravenous drug addiction was found in 20.3%, a history of operations/transfusions was found in 3.8%, indentation was found in 1.9%, and suspicious sexual contact was found in 1.5%. The rate of HBsAg positivity was 2.6% and the ratio of cases who were anti-HBs positive was 35.0% and immunity was achieved with vaccination in 43% of these cases. Anti-HCV was positive in 17.7%. HCV RNA was at measurable levels in 48.9% of the cases. In cases with HCV,

genotype 3 was detected in 97% and genotype 1 was detected in 3% of cases. No HBV and HCV association was detected in the cases.

Conclusions

In prisons, there are individuals who have hazardous behavioral patterns, who have been in prison due to violence, abuse and substance abuse. As most of the drug addicted patients continue to use substance in prisons; the common use of infectious materials, tattoo and other situations causing contact with blood increase the risk of blood borne infections. In our country, precautions should be taken also for the increased risk of these events and the community should be informed.

Practical Recommendations for Obesity

Rahman Kuri¹, Turan Set², Elif Altunbaş Ateş²

¹Department of Family Medicine, Kanuni Education and Research Hospital, Trabzon, Turkey

²Department of Family Medicine, Karadeniz Technical University Medical Faculty, Trabzon, Turkey

Background & AIM: Obesity is a major public health problem in worldwide. It is associated with serious diseases such as dislipidemia, cardiovascular diseases, hypertension, type 2 diabetes mellitus and some types of cancer. In this study, we aimed to give information about practical methods for prevention and treatment of obesity.

METHOD: Several resources about obesity has been examined.

RESULTS: Patients must be aware of eating and physical activity habits. The studies reported that most of the entreated patients gained weight again. Therefore, practical lifestyle recommendations should be emphasized. These recommendations are primarily related to eating habits and exercise and can be listed as follows:

- o Pay attention to calorie and fat content
- o Avoid sweet drinks and fast food
- o Consume fruit and vegetable daily
- o Drink at least 2-3 liters of fluid daily
- o Chew solid foods thoroughly
- o Form an own serving plate
- o Not skip breakfast
- o Eat meals on time
- o Avoid snacking
- o Keep an eating list
- o Determine a routine place and time for exercise
- o Use stairs instead of elevator
- o Deal with housework and gardening
- o Go on foot for short distances
- o Don't do shopping when you are hungry
- o Park car on the furthest place
- o Don't watch tv more than 2 hours a day and 10 hours in a week
- o Control your weight once a week

CONCLUSIONS: For patients, it is necessary to adopt lifestyle changes and have a high level of awareness for treating obesity and maintaining of ideal weight. There are simple and effective lifestyle changes that can be applicable for everyone and all conditions. In order to get a successful result, we should give understandable, clear and easy recommendations by taking the most suitable method for each patient into consideration.

³Özten Biçici, Verda Erdal, Gülay Arslan, Nuriye Birlık, Yeliz Acar, Salih Özgür, Department of Pediatrics, Ödemiş Government Hospital, Ödemiş, Turkey

(Background & AIM: Attitudes and behaviours towards usage of medication can vary in society. People has concerns about the side effects of the drugs and the drug usage were accused of many factors. The study objective was to evaluate attitude and practice of parents towards medication usage for their children's diseases

METHODS: Questionnaire based study was carried out in parents of admitted children in İzmir Tepecik Training and Research Hospital and Odemis State Hospital in 2014. Respondents were surveyed with 27 questions about parents attitudes against diseases and usage of medications. SPSS 20.0 statistical program package was used for data analysis.

RESULTS: The study included 208 participants. %10.09 of participants (n:21) were fathers, %93.1 of them were mothers. The majority of the parents (n:150, %72,11) were primary school graduates. 16 parents (%7.69) consult non-physicians about medications, 77 (%37.01) parents use herbal medicine. Medications consisting of analgesics and antipyretics groups are used without consult of physicians. 81 Parents (%38.94) had these medications as a spare at home. All participants were following expiration dates of the drugs. 21 of the parents (%10.09) recommended these medications -which they have had clinical benefits- to their relatives. 180 people (86.53%) asked information about prescribed drugs and 207 individuals (%99.51) used the medications as prescribed. The majority (n = 195, 93.75%) had read the prospectus. In case of the adverse effects 171 parents stated that they didn't benefit from the medications, 163 parents consulted the physician and referred to the hospital. 201 parents (%96.63) reported that they would dispose of the non-used medication

CONCLUSIONS: The study represented that parents had proper attitude about the usage of medications. This study is limited by the data from small-scale population from the particular region)

Painful shoulder in Primary care patients

Delia Rodriguez¹, Patricia Marquez², Maria Del Carmen Fernandez¹, Jose Maria Segura¹

¹Centro de Salud Canalejas, Gran Canaria, Spain

²Clinica Cajal, Gran Canaria, Spain

INTRODUCTION:

Shoulder pain is the third most common cause of musculoskeletal consultation in primary care. Any pain or disability in it, affects a person's ability to carry out daily activities.

Our study determines in a period of time from October 2011 to September 2014 in a Primary Care Centre of Gran Canaria; the number of adults consulting painful shoulder (non traumatic, non related to malignant diseases or inflammatory diseases), its distribution and management of them.

METHODS: Observational, descriptive and retrospective study was designed. The data was collected from the electronic clinical registries.

RESULTS: 1976 cases, 750 (38%) men, 1225 (62%) women, with an average age of 58 (95% CI.) The most common diagnosis was codified as unspecified shoulder pain 92.04% followed by rotator cuff tendinitis 5,80% and 0.9%

calcified tendonitis. All cases were firstly managed by GP and 32.4% were referred to specialists.

DISCUSSION: Importance in primary care due to its prevalence, of a good diagnosis and treatment of the principal shoulder pathology (frozen shoulder, rotator cuff disorder, glenohumeral joint arthritis and instability), to avoid chronicity and complications. Management should be multidisciplinary, including analgesics, relative rest and access to rehabilitation programs.

Environmental Factors Contribute to Pulmonary Tuberculosis in North Minahasa, North Sulawesi, Indonesia

Henry Palandeng¹, Grace Kandou², Herlina Butiop³

¹Department of Community Medicine, Faculty of Medicine, Sam Ratulangi University

²Public Health Faculty, Sam Ratulangi University

³Medical Student at Faculty of Medicine, Sam Ratulangi University

Pulmonary tuberculosis (TB) remains health problem throughout the world, including in Indonesia. Efforts to eliminate cases of pulmonary tuberculosis in Indonesia still has many obstacles. Environmental factors contribute to the high prevalence of pulmonary tuberculosis. Of the 33 provinces in Indonesia highest prevalence of pulmonary tuberculosis derived from three provinces, namely Jakarta, Banten, and North Sulawesi. This study aims to investigate the relationship between household contact and physical environmental factors homes with pulmonary TB incidence in the region of Wori, North Minahasa in North Sulawesi. This study was a cross sectional study with independent variables studied are household contacts, ventilation, and temperature of the room. Analysis using the chi-square test showed that there is a relationship household contacts with pulmonary TB incidence with $p = 0.016$, while the variable ventilation $p = 0.278$ and $p = 0.677$ at room temperature showed no association with the incidence of pulmonary tuberculosis in the village of Wori, North Minahasa, North Sulawesi, Indonesia.

General Practitioners' attitudes towards serum immunoglobulin testing in the South of Ireland: a qualitative study

Sharon L Cadogan¹, Sheena M Mchugh¹, Colin P Bradley², John P Browne¹, Mary R Cahill³

¹Department of Epidemiology and Public Health, University College Cork, Cork, Ireland.

²Department of General Practice, University College Cork, Cork, Ireland

³Department of Haematology, Cork University Hospital, Cork, Ireland

BACKGROUND: Research suggests that variation in laboratory requesting patterns may indicate unnecessary test use. Requesting patterns for serum immunoglobulins vary significantly between General Practitioners (GPs). This study aims to explore GP views on testing to identify the determinants of behaviour and recommend feasible intervention strategies for improving immunoglobulin test use in General Practice.

METHODS: Qualitative semi-structured interviews were conducted with GPs requesting laboratory tests in the South of Ireland. A random sample of GPs were purposively sampled based on the sampling criteria of: location (urban/rural); length of time qualified; and practice size (single-handed/group). Interviews were carried out between December 2014 and February 2015. Interviews were transcribed verbatim using NVivo 10 software, and analysed iteratively using thematic analysis. Emerging themes were then mapped to the theoretical domains framework (TDF), which identifies 12 domains that can enable or inhibit behaviour change. The behaviour change wheel and behaviour change technique (BCT) taxonomy were then used to recommend potential intervention strategies.

RESULTS: Sixteen GPs were interviewed, including ten males and six females. Preliminary analysis, using the TDF and BCT taxonomy, found that serum immunoglobulin test use in General Practice is influenced by many social and contextual factors. The main domains from the TDF which emerged were: 'knowledge', 'environmental context and resources', 'social influences', 'beliefs about capabilities', 'beliefs about consequences', with the findings identifying a need for 'shaping knowledge'. In particular, GPs identified education and feedback strategies as feasible interventions to change their behaviour.

CONCLUSIONS: Identified GP challenges with serum Immunoglobulin testing included difficulty interpreting test results, patient expectations, personal experiences, and the lack of implementation of guidelines and knowledge about when to test for serum immunoglobulins. Study findings and the application of the TDF and BCT taxonomy, will inform the development of a feasible intervention for improving immunoglobulin test use in General Practice.

Keywords: laboratory testing, health services research, Immunoglobulins, haematology, qualitative research, health care interventions,

Table 1: Seven of the 12 theoretical domains beliefs were identified during the coding of the transcripts

Theoretical domains belief identified	GP quotes to support identified domain
Knowledge	"...some GPs....would have a much better grasp or understanding of them. Maybe that is part of my issue that I don't fully understand them, and as I say in the rare incidence that I am doing them, I am really clutching at straws trying." (I015)
Behavioural regulation	I think the education strategy has to be built in with reminders"...a CME meeting discussing it or whatever would be good but we don't see enough to remember all the details of what is said so you probably need that reminder of what is said coming out with the result." (I003)
Beliefs about capabilities	"I feel my ability to triage them is poor, and you don't want to be ringing haematology all of the time" (I013) "You know any abnormalities at all, I tend to refer...I have serious difficulty interpreting them." (I014)

Beliefs about consequences	<p>“Yeah yeah, basically, I don’t want to miss them but I don’t want to be a doing wasteful tests either”. (I010)</p> <p>“...some of the time, the patient is actually recovered and your thinking aw h do I really want to follow this up?” (I015)</p>
Memory/attention/decision-making	<p>“I’m learning to live with slightly abnormal Igs in recent years and this whole thing of Monoclonal Gammopathy of Uncertain Significance and just keep monitoring them.” (I005)</p>
Environmental context	<p>“Some doctors don’t live well with uncertainty even in primary care.” (I005)</p> <p>“Pressure time also causes us to do tests.” (I005)</p>
Social/professional role	<p>“...we don’t have a huge call to do Igs really because I would consider that to be something that a specialist say a haematologist...would have interest in...” (1007)</p>

Table 2: Suggested intervention strategies identified by applying the TDF and BCT taxonomy to the study findings

TDF domains	COM-B	Construct	Strategy examples
Knowledge. Memory, attention and decision-making processes. Behavioural Regulation Beliefs about capabilities/consequences	C- (Psych.)	Shaping knowledge,	Education: Information about MGUS, guidelines on when to request and how to interpret results.
	C- (Phys.) M- (Refl.)	Natural consequences, Comparison of outcomes	Persuasion: Clearly communicate situations where IG testing is not beneficial. Persuasive communication of the information, supported by consultant haematologists and GPs.
Environmental context, memory, attention, decision-making processes and social/professional role	O- (Phys.) C- (Psych.) C- (Phys.)	Antecedents, Associations	Environmental restructure/enablement: Restrict the availability of the test at the laboratory end, eg. Reasons stated for request. Provide electronic notes detailing consultant advice (ideally provided on the end of the results).

TB-DM Score: a new score of TB comorbidities in DM patients

Fabianto Santoso¹, Steven Zulkifly¹, Edo Prabudi¹, Trevino Aristarkus Pakasi², Indah Suci Widyahening²

¹Faculty of Medicine Universitas Indonesia, Jakarta, Indonesia

²Department of Community Medicine, Faculty of Medicine Universitas Indonesia, Jakarta, Indonesia

Background

Indonesia is facing double-burden diseases of tuberculosis/TB (communicable disease) and diabetes mellitus/DM (non-communicable disease). A collaborative framework for detection and management of TB-DM patients established by World Health Organization (WHO) and The International Union Against Tuberculosis and Lung Disease (IULTD) recommends acid fast bacilli (AFB) sputum smear and chest x-ray examination in DM patients with TB symptoms. However, DM patients in Indonesia often show non-specific TB symptoms, thus they often disagree to undergo chest x-ray examination. Therefore, a study was done, aiming to establish scoring system for DM patients with non-specific TB symptoms to decide for chest x-ray examination.

Method. This was a cross-sectional study conducted among TB and/or DM patients in Jakarta, Bogor (West Java), Ternate (North Maluku), Kupang (East Nusa Tenggara), and Manado (North Sulawesi). Subjects are categorized into DM group and TB-DM group. TB is diagnosed based on positive AFB sputum smear, while DM is diagnosed based on fasting blood glucose (FBG). Multivariate logistic regression are conducted based on seven indicators: (1) sex, (2) age, (3) smoking history, (4) close contact with TB patients, (5) body mass index (BMI), (6) BCG scar, and (7) FBG.

Result

There were 620 patients participated in the study. They were all DM patients registered in the primary care. Cut-off points of these seven variables are taken from literatures and previous studies. Based on multivariate logistic study, there are four indicators that can be used: (1) age, (2) smoking history, (3) BMI, and (4) close contact with TB patients. To decide that a DM patient needs to undergo chest x-ray examination, the score must surpass cut-off point of 3. The score can be categorized as low risk (score ≤ 3 , 53.3%) and high risk (score > 3).

Conclusion

The risk score can identify the risk of TB in DM patients.

"Evaluation of the Clinical Characteristics of Children with Henoch Schönlein Purpura in Samsun"

Burcu Sezer¹, Yonca Açıköz²

¹Department of Family Medicine, 19 Mayıs University, Samsun, Turkey

²Obstetrics and Pediatric Hospital, Samsun, Turkey

AIM: Henoch-Schönlein purpura (HSP), is the most common vasculitis in childhood. Although the etiology is unknown, it is generally held responsible for previous upper respiratory tract infection or some infectious agents. Classically non-thrombocytopenic palpable purpura is accompanied by arthritis/arthralgia, abdominal pain and renal involvement. The demonstration of clinical features is important to make patients care plan. In this study, we aimed to evaluate the epidemiologic, geographic and clinical features of children diagnosed with HSP followed up in Samsun Obstetrics and Pediatric Hospital over a five-year period.

METHODS: From April 2010 to May 2015, the epidemiological, clinical and laboratory findings of all patients with diagnosis of HSP were collected by reviewing medical files retrospectively.

RESULTS: One hundred and twelve children (49 females, 63 males) aged between 2.5-17 years (avg. 7.4 years F, 8.7 years M) included in the study. Previous upper respiratory tract infection was determined in 39 patients (%34) and previous gastroenteritis in 1 patient (%8). The first symptom was purpura in 44 patients (%39), abdominal pain in 4 patient (%3), arthritis/arthralgia in 3 patients (%2), macroscopic hematuria in 1 patient (%8). Purpura was finding seen in all patients, gastrointestinal involvement occurred in 58 patients (%51.7), joints involvement in 48 patients (%42.8), renal involvement in 44 patients (%39.2), scrotal involvement in 12 patients (%19). Familial Mediterranean Fever (FMF) was determined in 3 patients (%2).

CONCLUSION: The epidemiologic and clinical features of patients with HSP followed up in our clinic are similar to the literature. In our patients we observed gastrointestinal and renal involvement either at the beginning of the disease and in progress of time. It is very important that the patients with HSP and their families should be informed about the course of the disease, varying in the wide spectrum, and also regular medical examination of the patients.

Keywords: Henoch-Schönlein purpura, children, vasculitis

P-1166

An Investigation into the Knowledge, Attitudes, and Behaviors of Physicians about Rational Drug Use

Mahmut Yılmaz¹, Zeynep Hazıroğlu Ökmen², Hatice Rümeysa Dülger², Halime Dilber Kiraz², Dilek Toprak²

¹Department of Family Medicine, Dicle University, Medical Faculty, Diyarbakir, Turkey

²Department of Family Medicine, Sisli Hamidiye Etfal Training and Research Hospital, Istanbul, Turkey

AIM: Rational drug use is defined as "the use of right drugs by patients in adequate dose for the sufficient duration and appropriate to their clinical needs at lowest cost both for themselves and the community". The steps of rational drug use include the establishment of correct diagnosis, determination of prognosis and goals of treatment, revision of treatment options, selection of appropriate treatment modality, and, if needed, prescription and follow-up of right drugs.

RESULTS: The study included 176 physicians who examined 3-300 patients a day. Of the physicians, 53.4% (n=94) spent less than 5 min and 13.1% (n=23) of them performed a whole system examination for each patient. 9.1% (n=16) of them didn't query liver and kidney function disorder and drug allergy in their patients. Most of the physicians (72.7%; n=128) explained their patients their diagnosis. Only 32.4% (n=57) of them warned their patients about the side effects of drugs. More than half of them (61.4%; n=108) advised non-drug treatments to their patients. The most common resources used by physicians for prescribing drugs were as follows: the views of colleagues (59.1%; n=104), Vademecum (54%; n=95), drug-related websites (51.7%; n=91), medical books (48.3%; n=85.9), and the commercial advertisements delivered by pharmaceutical companies (19.9%; n=35). More than half of them (56.8%; n=100) had knowledge about the side effects of the drugs, whereas 42.6% (n=75) of them had knowledge about the side effects of some drugs. It was revealed that only 15.9% (n=28) of them had correct knowledge about the prices of three drugs.

CONCLUSION: Physicians spend too little time for the examination of each patient and the presence of liver and kidney function disorder and the history of drug allergy are not queried during drug prescription. Physicians are

influenced by pharmaceutical companies and they have limited knowledge about the side effects of drugs. Most of the physicians have little information about the prices of drugs and they do not provide their patients with sufficient information about the drugs.

Keywords: physician, rational drug use

Departments and rates of the physicians included into the study

Family Medicine	Emergency Medicine	Internal Diseases	Pediatrics	Gynecology and Obstetrics	General Surgery	Other
46% (n=81)	10.2% (n=18)	10.2% (n=18)	9.7% (n=17)	8% (n=14)	5.1% (n=9)	11.2% (n=19)

(Approaching the Life Quality Among Different Patients in Treatment)

Nazlı Soysal, Umut Gök Balcı, Yasemin Şimşek, Hande İleri, Özgür Alavcı, Kurtuluş Öngel
Nazlı Soysal, Umut Gök Balcı, Yasemin Şimşek, Hande İleri, Özgür Alavcı, Kurtuluş Öngel, Family Medicine Department, Tepecik research and Training Hospital, İzmir, Turkey

INTRODUCTION: Life quality is a broad concept that affected with person's physical health, psychological state, beliefs, social relations and their relationship with the environment. Biopsychosocial approach is the basic assesment method of patients in the Family Medicine to improve the quality of life; by this way, factors affecting the quality of life identified.

AIM: In this study, quality of life during treatment in different patient groups was assessed with WHOQOL-BREF-TR scale and factors affecting the quality of life were intended.

MATERIAL METHOD: Study was performed between 1 January 2014 to 31 May 2014 in Tepecik Training and Research Hospital inpatient medical and surgical branches. WHOQOL-BREF-TR scale, that validity and reliability study had done, was used to detect the quality of life of people in their physical, psychological, social and environmental areas. Statistical analyses of data were performed by SPSS 16.0 programe.

RESULTS: There were 352 participants in this study. 154 of them were men (43.8%) and 198 of them were women (56.3%). The average age of people was 54±18,2 (min:17, max:91). Of the patients who participated in the study, 176 (50%) hospitalized in internal medicine, 176 (50%) in the surgical departments. Of those; 23 (6.5%) had never married, 243 (69%) were married, 13 (3.7%) were divorced, 71 (20.2%) widowed, and 2 (0.6%) were separated. Widowed patients' social average score was significantly higher in female patients. Life quality of women in the social field, male patients was found to be significantly higher.

CONCLUSION: Quality of life scores of patients in surgical departments were high. Patients in the internal departments had lower life quality scores. Life quality of patients with chronic diseases such as hypertension, diabetes were lower than acute illness. Pain, weakness and limitation of motion were found to be the most important factors that affects quality of life.

Keywords: Quality of life, WHOQOL-BREF-TR, factors affecting life quality

P-1168**(The Impact of Anxiety on University Students And Their Daily Diet)**

Umut Gök Balcı¹, Yasemin Şimşek¹, Hande İleri¹, Özgür Alavcı¹, Kurtuluş Öngel²

¹Umut Gök Balcı, Yasemin Şimşek, Hande İleri, Özgür Alavcı, Department of Family Medicine, Tepecik Research and Training Hospital, İzmir, Turkey

²Kurtuluş Öngel, Department of Family Medicine, Katip Çelebi University, İzmir, Turkey

INTRODUCTION: Eating disorder is a risk factor among university students. Various studies in our country have showed that university students have not balanced eating habits

AIM: This study researched the eating habits and the influence of anxiety on eating habits of İzmir Katip Çelebi University Medicine students

MATERIAL METHOD: This study case was done in March-April-May 2014; based on 196 medicine students of Katip Çelebi University in their first, second and third classes. A survey was used to evaluate the eating habits of the students. The anxiety symptoms of the students were researched with the Beck Anxiety scale test. The data codification and statistic analysis were made with the Spss 18 windows computer program.

RESULTS: The study case had involved 196 student; 109 were female (55.6%) and 87 (44.4%) were male. The statistic parameters; age (p:0.000), usage of psychiatric drug (p:0.000), medical problems (0.006), study problems and obesity (0.018), eating disorder (guilt) (0.001), weighing frequency (0.001), change of eating habits before exams (p.0.032) have shown a significant correlation with Beck's Anxiety Scale Test.

CONCLUSION: In this study, the significant parameters correlated with anxiety were not studied before. Because of this each parameter should be researched in detail.

Keywords: (Anxiety, Eating habits, Students)

P-1169**The Knowledge, Attitudes and Behaviors of Postmenopausal Women in Osteoporosis**

Özge Berfu Gürbüz, Tuğba Onat, Rana Gündoğan, Kübra Uyar, Tuba Aydın, Vildan Mevsim

Department of Family Medicine, Dokuz Eylül University, İzmir, Turkey

BACKGROUND & AIM: The aim of this study was to determine the knowledge, attitude and behaviors of postmenopausal women (PMW) about osteoporosis.

METHOD: A cross-sectional analytical study design was applied to 200 PMW over the age of 45 in a postmenopausal clinic. Survey administered which's questions about demographics, osteoporosis knowledge, attitudes, and behaviors. Osteoporosis status of these patients was also assessed according to the DEXA results. Participants were questioned about osteoporosis knowledge, attitudes, and behaviors with respectively 13, 6, 9 questions. The knowledge score (KS) ≥ 26 (13-39), the attitude score (AS) ≥ 14 (7-21) and the behavior score (BS) ≥ 20 (10-30) considered 'good'. Data was analysed using descriptive, chi-square statistics, student t test and correlation analyses.

RESULTS: The average age of the participants 59.58 ± 7.9 where the average age of menopause was 50.66 ± 1.96 . 23.5 % of the participants had bone resorption. The average KS of the participants was 31.93 ± 4.83 ; the average AS was 16.41 ± 2.35 ; and the average BS was 19.73 ± 3.88 . KS of 14 %, AS of 16%, and BS of 41.5 % of the respondents was 'low'. 44.7 % of the participants with low score of knowledge and 61,7% of those with low score of behavior has osteoporosis. 37,5% of the participants with bone fractures has low KS and 41.7 % of those has bad AS. 89 % of the participants with good KS, have good attitude scores and 62,9% of those have good behavior scores also. There is moderately strong correlation between knowledge, attitudes and behavior scores.

CONCLUSION: Knowledge attitudes and behaviors of PMW about osteoporosis and its prevention is effective in preventing osteoporosis.

Keywords: postmenopausal women, osteoporosis, knowledge, attitude, behaviors

Evaluation of the Relationship Between Sleep Disorders and Smoking and Use of *Nicotiana rustica* (Smokeless Tobacco)

Hamit Sırrı Keten¹, Hakan Öney², Celal Kuş³, Özgür Ersoy⁴, Oğuz Işık³, Mustafa Çelik³

¹Department of Family Medicine, Kurtul Family Health Center, Kahramanmaraş, Turkey

²Faculty of Arts and Humanities, Arts, Sciences & Technology University in Lebanon, Beirut, Lebanon

³Department of Family Medicine, Medical Faculty, Kahramanmaraş Sutcu Imam University, Kahramanmaraş, Turkey

⁴Department of Public Health, Medical Faculty, Cukurova University, Adana, Turkey

BACKGROUND: The present study aimed at evaluating the relationship between sleep disorders and smoking and use of *Nicotiana rustica* (smokeless tobacco).

METHOD: The present study was conducted in 10 coffee houses in Kahramanmaraş province located in the Mediterranean Region of Turkey between April 1st 2014 and September 1st 2014. The participants were informed of the study and 180 male subjects that provided written consent were included in the study. The smokeless tobacco users group was comprised of 60 subjects who were using *Nicotiana rustica* and the smoker group was comprised of 60 subjects who were smoking cigarettes. The control group was comprised of 60 subjects who indicated themselves as have never used any tobacco products. The Epworth Scale was used to evaluate excessive daytime sleepiness and the Pittsburgh Index was used to determine sleep quality. The maximum total score in Pittsburgh Index is 21 points and it contains 7 sub-dimensions, and maximum total score in the Epworth Scale is 24 points.

RESULTS: The mean age of the study subjects was 41.97±14.02 (min=18, max=65) years. The mean score in the Epworth Scale was 4.30±2.80 in the control group, 4.23±3.12 points in the smokers group, and 4.91±4.02 points in smokeless tobacco group. The study groups achieved similar scores in the Epworth Scale ($p=0.471$). The mean score in the Pittsburgh Index was 7.63±2.50 in the control group, 8.11±2.70 points in the smokeless tobacco group, and 8.95±3.04 points in the smokers group. The scores achieved in Pittsburgh Index were significantly higher in the smokeless tobacco group compared to other groups ($p=0.033$).

CONCLUSION: The study found that subjects that used tobacco products experienced daytime sleepiness similar to subjects who did not use tobacco products. Sleep quality was significantly lower in the smokeless tobacco group compared to smokers and subjects in the control group.

The Determination Of Acute Effects Of Maras Powder (Smokeless Tobacco) On Hemodynamic Parameters

Hamit Sırrı Keten¹, Soner Ölmez², Hüseyin Üçer³, Fatih Yıldırım³, Oğuz Işık³, Mustafa Çelik³

¹Department of Family Medicine, Kurtul Family Health Center, Kahramanmaraş, Turkey

²Department of Family Medicine, Samsat Family Health Center, Adıyaman, Turkey

³Department of Family Medicine, Medical Faculty, Kahramanmaraş Sutcu Imam University, Kahramanmaraş, Turkey

BACKGROUND: In this study it is aimed to determine the acute effects of maras powder (smokeless tobacco) on hemodynamic parameters.

METHOD: This study was conducted in 20 coffee houses in Kahramanmaraş city on 140 voluntary males. Brachial systolic blood pressure (SBP), diastolic blood pressure (DBP) and the heart rate (HR) were measured from the left arm by automated digital oscillometric device. The first HR, SBP and DBPs after a relaxing period of 15 minutes were accepted as the basal values. After the basal measurement, the measurements were performed on 5., 10., 15. and 20th minutes. Following the initial measurement, the participants were made to place and keep 1,5 grams of maras powder between the gingiva and the lower lip for 10 minutes. The measurements of the 5. and 10. minutes were performed when maras powder was still in participants' mouths. After measurement of the 10. minute, maras powder was taken out of the participants' mouths. $P<0,05$ was accepted to be statistically significant.

RESULTS: The mean age of the participants was 51.64 ± 13.46 . It was found that the HR, SBP and DBP values of 5., 10., 15. and 20. minutes were significantly higher compared to basal measurements ($p < 0.05$). It was determined that the HR, SBP and DBP were the highest at 5. minute when maras powder was still in mouth and decreased in following measurements.

CONCLUSIONS: We revealed that maras powder increased the HR, SBP and DBP acutely and significantly in our study. This effect of maras powder on hemodynamic parameters indicate that it is an important risk for cardiovascular diseases.

Nicotine Dependence and Related Factors

Ayşe Didem Esen, Seçil Arıca, Begüm Koçar, Ayla Karaca, Umut Karagöz, Gülten Belgin, Şeniz Suvan
Department of Family Medicine, Okmeydani Research and Training Hospital, Istanbul, Turkey

BACKGROUND: The aim of this study is to define properties of patients and risk factors who has applied to smoking cessation unit in our hospital.

METHODS: The study included 415 cases who applied smoking cessation unit between january and april in 2015. SPSS software version 15.0 was used for statical analysis. Destriptive analyses, chi-square tests, in parametric data pearson correlation analysis and in non-parametric data spearman correlation analysis was performed. Logistic regresyon analyzis was used to define risk factors of smoking.

RESULTS: 415 cases include 172 male, 243 female. 16% attended smoke cessation unit by doctor advice. 214 cases were living in the house with smokers Mean fagerstrom nicotine addiction level was 5.64 ± 2.59 and mean CO level was 7.82 ± 5.16 . The median ages of beginnig to smoke were in female 17(8-47), in male 15 (7-49) and the difference was significant($p = 0.0001$). There was not a significant correlation between education level ($r = 0.123$ $p = 0.07$). There was a positive correlation between amount of cigarettes smoked per day and fagerstrom score ($r = 0.618$, $p = 0.0001$). There was a positive correlation between cigarettes per day and CO level. Fagerstrom score and CO level had a positive correlation ($r = 0.337$, $p = 0.001$). There was negative correlation between how much minutes passed after last cigarette smoking time and CO level ($r = 0.226$, $p = 0.001$). Amount of cigarettes per day and years of smoking had a positive correlation ($r = 0.129$, $p = 0.008$). 54.7% of male and 60.5 % of female smokers found to have high grade nicotine dependence. Beginning to smoke before age of 15 and low education level were not a risk factor for high grade nicotine dependence.

CONCLUSION: Fagerstom score was correlating with amount of cigarette per day and CO level but not correlating with age of beginning to smoke and years of smoking. Also some demographic features of patients were effective on nicotine dependence

Keywords: Fagerstrom score, nicotine dependence, smoking cessation

Recreational Drugs: what the family physician should know

Vanessa Carvalho¹, Leonor Troni², Catarina Bastos³, Arnaldo Abrantes⁴

¹USF Cynthia

²USF D. Jordão

³USF Sobreda

⁴USF Dafundo

INTRODUCTION: Recently several of new recreational drugs have arisen. It can be synthetic compounds or originate in natural products. Psychoactive substances are easily accessible, providing a challenge for health professionals that should play an important role in preventing consumption.

OBJECTIVE: Review the approach of recreational drug use in Primary Health Care.

METHODOLOGY: Proceeded to the literature of Evidence Based Medicine databases, using the keywords: recreational drugs, primary care. The search was limited to articles in English and Portuguese published between 2005 and May 2015.

RESULTS: The clinical manifestations of drug abuse vary according to the route of administration, concentration, excipients, and can be intensified by concomitant ingestion of alcohol. It may be variable and often difficult to attribute to drug use. The most important is the recognition of dependence. It's difficult to distinguish between experimentation, frequent use and abuse. The lower the age of onset of drug use, the higher the risk of pathological consumption and dependence in adulthood. The main risk factors are family history of addiction, school failure, low self-esteem, aggressive or impulsive personality, psychiatric pathology, family instability and low socioeconomic level. Intervention should be initiated by a motivational interview guided by an empathetic attitude without prejudice. In the anamnesis it's important questions about professional and social activities, family atmosphere, food and drug habits and ultimately toxic habits. The complete physical examination should be performed and further diagnostic tests may be need.

DISCUSSION: Most of the recreational drug users use them temporarily and intermittently. It's recommended a phased intervention that should be initiated by a motivational interview. If the patient does not respond to this brief intervention but are motivated, referral for more specialized care should be considered. The family physician should be able to monitor drug use, its cessation and the progression of physical and mental symptoms.

Keywords: Recreational Drugs, primary health care, intervention

{Publication status of all scientific papers presented in WONCA Europe Conferences between 2006-2013: Reflections to research quality in primary care }

Adem Ozkara, Rabia Kahveci, Ummugulsum Yildiz, Ismail Kasim, Irfan Sencan, Rumeysa Agbektas

Department of Family Medicine, Ankara Numune Training and Research Hospital, Ankara, Turkey

OBJECTIVE:

Our aim is to find out the quality of researches in primary care by detecting transforming ratio of presentations to manuscripts and quality levels via several quality indicators (degree of journal, impact factors and citations etc.) of WONCA Europe Conferences, which constitute supreme presentation level of primary care researches.

METHODS:

Five thousand seven hundred thirty-four abstracts that were presented at Wonca Europe Conferences between 2006 and 2013 were evaluated in this study. Publication status was assessed from PubMed, Google Scholar and Clinical Key. Journal name, publication date, impact factors, inclusion in Index Medicus and number of citations were determined. Mean duration between date of presentation at the congress and date of publication was also calculated. Abstracts were assessed according to their being presented as posters, oral presentations and receiving an award.

RESULTS:

Table 1

Database searches are still running and final results are planning to be shared in WONCA Europe 2015.

CONCLUSIONS:

Primary care is a real indicator of health status of community. Hospital data only will not reveal health status, disease distribution, community reaction to diseases or effect of diseases on community. That's why research in primary care is a necessity. Value of research is determined by research quality. We believe this study would contribute to comment on success of research by years between 2006 to 2013.

"Use of Antibiotics for Upper Respiratory Tract Infections at the Family Medicine Out-patient Clinic at a University Hospital"

Seda Coskun, Zehra Dağlı, Ayşe Selda Tekiner, Ayşe Gülsen Ceyhan Peker, Mehmet Urgan

Ankara University Faculty of Medicine, Department of Family Medicine, Ankara, Turkey

OBJECTIVE: Antibiotics are mostly prescribed for respiratory tract infections in primary care. For ideal antibiotic use, the right antibiotic should be given at effective doses with optimum range for appropriate duration after accurate diagnosis. The study aimed to determine oral antibiotic preferences and rates in patients with upper respiratory tract infections (URTI) at a family medicine out-patient clinic.

METHODS: The retrospective, cross-sectional, and descriptive study included 434 patients who were prescribed for URTI for once at a family medicine out-patient clinic of a university hospital in Ankara between August 1, 2012 and July 31, 2013. Descriptive statistics were given as mean±standard deviation and percentage. Chi-square test was used for differences between the groups. Any p<0.05 was considered statistically significant.

RESULTS: Mean age of 434 patients (36.6% male, 63.4% female) was 33.45±16.36 years. The diagnoses made were acute tonsillitis (30.9%), acute sinusitis (30.0%), acute pharyngitis (16.4%), undifferentiated URTI (11.8%), acute nasopharyngitis (9.2%), influenza (1.2%), chronic sinusitis (0.5%), and both acute sinusitis and acute pharyngitis (0.2%) in order of frequency. Amoxicillin/clavulanic acid (59%), symptomatic treatment (27.9%), and clarithromycin (6%) were prescribed most frequently. The most common antibiotic groups preferred were synthetic penicilines (27%), macrolids (7.3%), and cephalosporins (4.1%). There was no statistically significant difference between the diagnosis and the method of treatment chosen (p<0.001). No antibiotics were prescribed to patients with influenza, whereas 17.5% of those with acute nasopharyngitis received antibiotic treatment.

CONCLUSION: The patients with URTI were most commonly treated with amoxicillin/clavulanic acid, however, antibiotic therapy was initiated in one fifth of viral acute nasopharyngitis cases. That may be because most of the care of the patients was given by family medicine residents relatively less experienced in medicine, therefore, rational antibiotic use and patient-physician communication should be emphasized in both continuous medical education and specialty training.

Evaluation of Daily Life Activities in Home Care Patients

Sevim Ogulmus¹, Irep Karatas Eray¹, Pinar Ilhan², Aylin Baydar Artantaş¹, Tuncer Kilic², Mehmet Ugurlu²

¹Department of Family Medicine, Atatürk Training and Research Hospital, Ankara, Turkey

²Department of Family Medicine, Yıldırım Beyazıt University Faculty of Medicine, Ankara, Turkey

OBJECTIVE: The purpose of this study is to determine the ability to do the daily activities of home care patients.

METHODS: The sample of the research includes 303 patients who were registered in a database of a training and research hospital offering home care services. Research data were collected through The Katz Index of Independence in Activities of Daily Living. The Index was developed to provide a standardized quantitative measure of functional changes in the chronically ill and the elderly. The Index ranks adequacy of performance in the six functions of bathing, dressing, toileting, transferring, continence, and feeding. A score of 6 indicates full function, 4 indicates moderate impairment, and 2 or less indicates severe functional impairment(1).

RESULTS: Of the 303 subjects in the study, 207(55.8%) were females and 96(44.2%) were males, with an overall mean age of 75,39. It was determined that the patients had a Katz Index of Independence in Activities of Daily Living mean score of 1,92 and 66,6% were severe dependent, %14,6 were semi-dependent. %76,2 of the primary caregivers were women with an overall mean age of 57,01. The caregivers were mostly university graduates(%39,6). Only %5,8 of the caregivers were trained for caring patient.

Conclusions: The result of this study show the needs of organizations and health care professionals. It is suggested that necessary care and help should be provided to support independence of elderly people in their daily life activities. Most of the homecare patients are dependent to caregivers so there is a need for formal training for the caregivers.

{Do all abstracts end up with publications in peer-reviewed journals?: An overview of Wonca Europe 2008 Istanbul Conference}

Adem Ozkara, Rabia Kahveci, Ummugulsum Yildiz, Ismail Kasim, Irfan Sencan, Rumeysa Agbektas
 Department of Family Medicine, Ankara Numune Training and Research Hospital, Ankara, Turkey
 Aim

Our aim is to review abstracts that were presented in Wonca Europe 2008 Istanbul Conference and find out publication ratio of these abstracts in peer-reviewed journals as of today. This is part of a larger project which explores research quality in primary care.

Methods

Oral and poster presentations of Wonca Europe 2008 Istanbul Conference are reviewed. Manuscripts investigated in several scientific search portals according to authors, key words and title. All found manuscripts listed and classified as SCI classified journals, national indexes and peer-reviewed journals. Contacting with authors, where possible, is also planned not to miss any potential paper. As a last step we calculate publication ratio of reports as well as determine publication quality by journals' classification.

Results

The total number of abstracts were 954 (Oral Presentation 319, Poster Presentation 635) from a total number of 49 countries. Database searches are still running and final results are planning to be shared in WONCA Europe 2015.

Table 1

Conclusions

It is important to increase quality of research in the primary care. Although one conference will not be enough to map the whole research quality and how well abstracts form the basis for future articles, we believe this study would still give us a good idea about the current status in Europe. A broader project tackling several different aspects will help us outline current activities in primary care research field in Europe.

Homicides Against Women of Reproductive Age: a Public Health Problem of a Brazilian Metropolis

Ana Luísa Franco Moura, Gustavo Aguilar Alvarenga Amorim, Lara Louise Guimarães Silveira, David Carvalho Rezende, Wallace Pinheiro Rodrigues, Lorena De Almeida Ribeiro Prudente, Vinicius Bernardes Mendonça Damasceno, Natália Carasek Matos Cascudo, Camila Garcia De Souza, Aysa Teles Abrão Trad
School of Medicine, Federal University of Goiás, Goiânia, Brasil.

Since 1990, violence against women has been considered by the World Health Organization a problem of public health, that can even result in death of woman by murder.

The aim of this work was to show the importance of homicides as cause of death between women of reproductive age in the city of Goiania - GO.

We used as method the analysis of data from the death declarations of women in reproductive age (10 to 49) residents in the city of Goiania - GO, in the period of January to December of 2013. The variables age, cause of death, marital status and education were collected for the study. The search of these data was carried out in the Health Information Division of the Department of Epidemiology at the Municipal Health Secretary of Goiania - GO. In 2013, murders were responsible for 10,83% of deaths between women of reproductive age in the city of Goiania - GO. The age group with the highest number of cases was 20-29 years, with 43,14%. As the civil state, 72,55% of women who died by murder were divorced or single. As for education, 62,74% had completed only elementary school. On the other hand, only 5,88% had completed higher education.

With this work, it was concluded that murders are an important cause of death between women of reproductive age in the city of Goiania - GO. Measures as largest investments in education and awareness campaigns on violence against women may show effective in reduction of these killings.

Keywords: Women, murder, mortality.

P-1179**Cigarette Smoking and Thiol /Disulphide Homeostasis**

Ahmet Keskin¹, Yusuf Üstü¹, Basri Furkan Dağcıoğlu¹, Tuncer Kılıç¹, İrep Karataş Eray², Aylin Baydar Artantaş², Mehmet Uğurlu¹

¹Department of Family Medicine, Yıldırım Beyazıt University, Ankara, Turkey

²Department of Family Medicine, Atatürk Training and Research Hospital, Ankara, Turkey

OBJECTIVES: Thiol/ disulphide homeostasis has a critical role on cellular events like antioxidant protection and apoptosis. It is known that there is an increase of oxidative stress accompanying chronic diseases. It is shown in many studies that smoking may enhance oxidative stress through the production of reactive oxygen radicals in smoke and weakening of the antioxidant defense systems. We aimed to investigate the relationship between cigarette smoking and thiol/disulphide homeostasis which is a new indicator for the oxidative stress.

METHODS: Thiol / disulphide homeostasis parameters were studied in the blood samples of 62 smokers and 68 non-smokers in the control group, who were 18 years or over and admitted to outpatient clinic of our hospital between December 2014 and March 2015. Subjects were selected from 574 patients according to exclusion criteria including history of chronic disease, alcohol consumption and malignancy. Venous blood samples were taken from all subjects and plasma obtained by centrifugation 15 min at 3600 rpm. After that, native thiol, disulphide, total thiol, index 1 (disulphide/native thiol), index 2 (disulphide/total thiol) and index 3 (native thiol/total thiol) levels were measured by an automated colorimetric analyzer. Statistical analyzes were performed on 130 patients who were included to the study.

RESULTS: Index 1 and index 2 levels of smoking patients were significantly higher than the control group [(p:0,018; Z:-2,37) and (p:0,005; Z:-2,78) respectively]. Native thiol, disulphide and total thiol levels tended to be higher on patient group too, whereas the difference was not significant.(Table 1)

CONCLUSION: These findings are the first results of our continuing study and we aim to finish the process with higher amounts of patient data in order to publish the final results. Further studies may reveal the clinical importance of dynamic thiol/disulphide homeostasis on many conditions like cigarette smoking.

Mortality by Cancer in a Female Population of a Brazilian Metropolis

Ana Luísa Franco Moura, Lara Louise Guimarães Silveira, Gustavo Aguiar Alvarenga Amorim, David Carvalho Rezende, Wallace Pinheiro Rodrigues, Lorena De Almeida Ribeiro Prudente, Vinicius Bernardes Mendonça Damasceno, Natália Carasek Matos Cascudo, Camila Garcia De Souza, Ayssa Teles Abrão Trad
School of Medicine, Federal University of Goiás, Goiânia, Brasil.

The progressive increase in life expectancy of the Brazilian population in recent decades has brought with chronic diseases, including cancer.

The aim of this study was to show the importance of cancer as a cause of death among women in the city of Goiania - GO.

The method used was the collection and analysis of data obtained from death certificates of women of childbearing age (10 to 49) living in the city of Goiania - GO. The variables type of cancer, age and education were collected for the study. The survey of all data was carried out in the Health Information Division of the Municipal Health Department of Epidemiology of the city of Goiania - GO. The period for data collected was from January to December of the year 2013.

In 2013, cancer accounted for 25.48% of deaths among women of childbearing age in the city of Goiania - GO. The five most common cancers were breast, with 34,17%; the cervical, with 10,83%; the intestine, 7,5%; Leukemia, 7,5%; and lung, with 6,67%. The age group with the highest number of cases was 40-49 years with 63,33%. On the other hand, the age group 10 to 29 years accounted for 9,17% of all cancer deaths. As for education, only 15,83% of women who died of cancer had a full university degree, while 31,67% of them had no schooling or had only completed elementary school.

With this work, it was concluded that cancer is a leading cause of death among women of childbearing age in the city of Goiania - GO, requiring policies aimed at public awareness of this fact, especially the attention to women who are in the fourth decade of life and/or who have low educational attainment.

Keywords: Women, cancer, mortality.

Nutritional Status of Home Care Service

Pınar İlhan¹, İrep Karataş Eray², Sevim Öğülmüş², Ahmet Keskin¹, Furkan Dağcıoğlu¹, Yusuf Üstü¹

¹Aile Hekimliği Ana Bilim Dalı, Yıldırım Beyazıt Üniversitesi Tıp Fakültesi, Ankara, Turkey

²Aile Hekimliği Ana Bilim Dalı, Atatürk Eğitim Araştırma Hastanesi, Ankara, Turkey

NUTRITIONAL STATUS OF HOME CARE SERVICE

OBJECTIVE: The growing need for home care services is due to the rising age of population, increasing rate of chronic illnesses and disabilities in Türkiye and around the world. An imbalance (deficiency or excess) of energy consumption, together with protein, and other nutrients' intake causes malnutrition. This study was designed to determine nutrition status of the patients who were registered in home care service.

The 'Malnutrition Universal Screening Tool' ('MUST') was designed to help identify adults who are underweight and at risk of malnutrition. 'MUST' has classified patients for their risk of malnutrition in an easy, rapid and reproducible manner. (1)

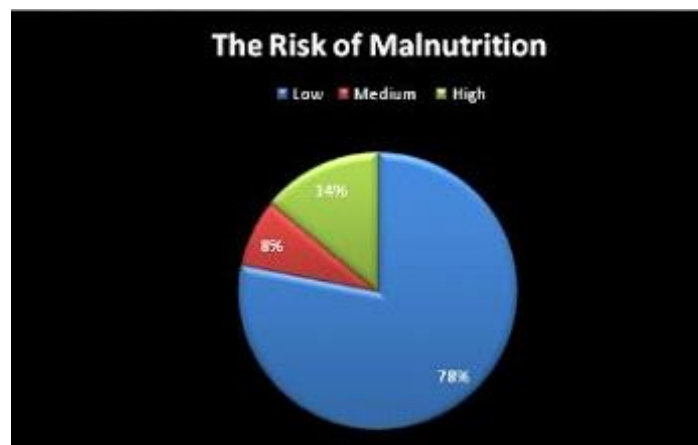

METHODS: This cross-sectional study was carried 303 patients who were registered in home care unit of Atatürk Research and Training Hospital in Ankara. 'MUST' was used to determine the nutrition status. Scores classified as low, medium or high risk.

RESULTS: In the study, most of the patients were women (n= 207). Mean age was 75 and 245 of the patients had at least one chronic illness. 21.87 % of the patients (n=63) were at risk of malnutrition (medium and high risk). And 11.55 % of them had decubit ulcer (n=35)

DISCUSSION: Malnutrition and risk of malnutrition are common among elderly patients. Primary care physicians who provide home care services have a primary role in the care of the such patients. 'MUST' could be used in the early diagnosis of malnutrition among these patients. Individuals who are at risk of malnutrition should be evaluated as soon as possible to receive the necessary treatment and dietary supplement. In summary, 'MUST' is provided to assess the nutritional status of patients for early diagnosis and this will positively effect general health status.

Chronic Pain Management: The Role of The Primary Care Prescriber

Josephine Rebecca Fowler

Office of Academic Affairs & Department of Family Medicine, JPS Health Network, Fort Worth TX USA

State and federal laws are in place to abate misuse of pain medication especially narcotics. As a result of laws and the onslaught of patients seeking narcotics, primary care physicians have decreased the number of prescriptions written for chronic pain and tend to refer those patients to a pain specialist. In an attempt to avoid "drug seeking" behavior and over writing of narcotics. Over the past years, the use of 'narcotics first' has continued to increase in emergency and primary care. In 2014, the most commonly prescribed narcotic pain medications in the state were reassigned to more restricted prescribing practices changing the way teaching hospitals are able to prescribe, namely reallocating responsibility to faculty. Training in pain management is needed.

Methods

Practice gaps were determined through a review of specialty clinic referrals for pain management with specific pain management ICD-9 codes. Educational needs were based on determined practice gaps and qualitative data. Three CME programs on Pain Management were conducted in various formats. Attendees were recruited using standard CME methods. Attendance was voluntary. A follow-up survey was administered to each attendee that filled out a survey at a session; the follow-up survey contained questions inquiring about the attendee's implementation of the material presented in the session(s) they attended. Outcomes were evaluated by analyzing responses on surveys and querying patient visits for pain management.

Results

Pain management education was received favorably. Participants stated they were willing to assess and change their practice. Acupuncture and alternative options were unfamiliar to most prescribing pain medication. A large amount stated that acupuncture could have helped their patients with pain.

Conclusion

Chronic Pain is a problem in many practices and varies across regions. Stepwise management is rarely used. Persistent education about a systematic approach to pain management is pertinent to improving prescribing methods.

Development and Validation of a Personality Type Inventory Based on Enneagram

Kenan Taştan, Zekeriya Aktürk, Memet Işık

Department of Family Medicine, Atatürk University, Erzurum, Turkey

INTRODUCTION: The Enneagram of Personality is an ancient model of human personality, which is principally understood and taught as a typology of nine interconnected personality types. There is no inventory in Turkish measuring Enneagram personality types.

AIM: The aim of this study was to develop a Turkish inventory based on the Enneagram principles.

METHODS: The final questionnaire consisting of 44 questions was applied to a sample of 156 Turkish-speaking participants using a Likert scale ranging from 0 to 6. Expert validation, factor analysis and internal consistency were applied. Data analysis was done with the SPSS version 20.

RESULTS: Of the participants 89 were females (57.4%) and 66 were males (42.6%). Mean age of the participants was 30.52±10.0 years. Most of the participants were university graduates/students (n=113; 72.4%). Cronbach alpha value for the total items was 0,839 with a split half value of 0.817 for part 1 and 0.757 for part 2. Guttman Split-Half Coefficient was calculated as 0.520. Confirmatory factor analysis showed that the nine components explained more than 60% of the total variance

In the confirmatory factor analysis all items except item 22 had factor loadings ranging from 0.411 to 0.829. Mean sensitivity and specificity of the instrument for detecting different personality types was high (82.8% and 97.8% respectively). While specificity was above 94% for all domains, sensitivity for type 4 personality was 66.7%.

DISCUSSION: We conclude that the Taştan Personality Type Inventory is an effective tool in identifying personality types according to the Enneagram principles in Turkish citizens.

Keywords: Personality types, Enneagram, Patient communication

Sleep quality and day time sleepiness in healthy adults with active or passive smoking (Early results)

Ayşe Yılmaz¹, Tuncer Kılıç¹, Melike Esen¹, Esra Demir¹, Ahmet Keskin¹, Basri Furkan Dağcıoğlu¹, İrep Karataş Eray², Aylin Baydar Artantaş², Yusuf Üstü¹, Mehmet Uğurlu¹

¹Department of Family Medicine, Yildirim Beyazıt University, Ankara, Turkey

²Department of Family Medicine, Atatürk Education and Research Hospital, Ankara, Turkey

BACKGROUND & AIM

It is well known that both active and passive cigarette smoking lead to severe health problems. Although there are several studies demonstrating impaired sleep quality with healthy adults with active smoking, data regarding passive smoking is limited. The aim of this study is to investigate sleep quality and day time sleepiness in healthy adults with active or passive smoking.

METHODS

We enrolled 48 healthy adults with active or passive smoking (18 of them were passive, 30 active smoker) and 27 healthy controls who had never smoked and had no regular exposure to cigarette. Pittsburgh Sleep Quality Index (PSQI) and Epworth Sleepiness Scale(ESS) questionnaire were used. Statistical analysis was done using SPSS 20.

RESULTS

The main demographic characteristics were comparable between groups. There was significant difference between control and any type of smoking group (active or passive) in terms of PSQI and ESS (Table1). PSQI and ESS scores of passive smokers were significantly high compared with the control group. PSQI and ESS scores of active smokers were significantly high compared with the control group. But no significant difference was seen between active and passive smoking group in terms of PSQI and ESS (Table 2,3,4).

CONCLUSION:

Passive smoking is associated with poor sleep quality as well as active smoking.

Topical estrogen therapy in labial adhesion

Daniela Pedrosa Costa¹, Sónia Manuela Rodrigues Moreira², Sofia Rendeiro Correia Pinto³, Célia Pinto Saraiva Oliva⁴, Pedro Miguel Paulino Pereira⁵

¹Unidade Saúde Familiar Torrão, Lousada, Portugal

²Unidade Saúde Familiar Torrão, Lousada, Portugal

³Unidade Saúde Familiar S. João, Oporto, Portugal

⁴Unidade Saúde Familiar Além D'Ouro, Gaia, Portugal

⁵Unidade Saúde Familiar Vale do Vez, Viana do Castelo, Portugal

Background & AIM:

Labial adhesion can be diagnosed in prepubertal girls in family practice. It's estimated prevalence is of 1.8% and occurs predominantly between 13-23 months of age. Mostly asymptomatic, it can complicate with local inflammation, dysuria, urinary tract infection and obstruction.

Our aim is to review the available evidence relative to the efficacy of topical estrogen in labial adhesion in comparison to other topical treatments.

METHODS:

Review on guidelines, systematic reviews and randomised controlled clinical trials on Medline/Pubmed database using the MeSH terms "labial adhesion" OR "labial fusion" OR "labial agglutination" AND "topical estrogens".

Studies in english, portuguese, spanish and french published between January 2005 and March 2015 were included. To evaluate the strength of recommendation and body of evidence, the Strength of Recommendation Taxonomy (SORT) of American Family Physician was used.

RESULTS:

A total of 9 articles were identified, 6 of which met the selection criteria: one systematic review (level of evidence, LE 1) and four randomised controlled clinical trials (three LE 2, one LE 3) that recommend topical estrogen use only in symptomatic cases. One randomised controlled clinical trial (LE 2) recommends the use of

topical estrogen whether the labial adhesion is symptomatic or asymptomatic.

Conclusion

Although the number of studies available are scarce, the results are relatively homogeneous, stating that topical estrogen can be used for labial adhesion resolution, primarily when it is symptomatic. Nevertheless topical corticoids are frequently the chosen treatment. We consider that the scientific evidence is insufficient to recommend in favour or against the use of topical treatments in labial adhesion.

Tobacco use among Yeditepe University students, and relationship between first experimented tobacco product and current use

Recep Erol Sezer¹, Özlem Tanrıöver¹, Güliz Dirimen Arıkan², Mehtap Kaçar¹

¹Yeditepe University Faculty of Medicine

²Yeditepe University Faculty of Health Sciences

Background and AIM: Although impressive progress has been made in tobacco control in Turkey, increasing tobacco use rates among young people remain a national concern. We aimed to describe the experimentation and use of tobacco products among university students, and to investigate the relationship between the first experimented product (a waterpipe product vs a cigarette) and current smoking rates.

METHOD: This questionnaire survey was conducted in the spring term of the 2014-15 academic year. The research ethics committee approval was received. The study subjects included all four-year students from the schools of medicine, pharmacy, dentistry, and health sciences of the Yeditepe University, Istanbul. The response rate was 97.5% (345/354).

RESULTS: The proportion of those who have ever experimented a tobacco product was 74% (256/345) with no significant difference by gender. Of those who have ever experimented a tobacco product, 50% experimented a waterpipe product first, while the other half experimented a cigarette first. There was no relationship between the first experimented product and current smoking rates. Of the 345 respondents 36.5% (126) were current smokers, 3.2% (11) former smokers, 60.3% (208) never smokers. The proportion of current smokers was 53.5% in males, 29.7% in females ($p < 0.001$). Among current smokers ($n=126$), 79.4% (100) were daily smokers, 20.6% (26) some-day smokers with no significant difference by gender. In all daily smokers, the daily used product was cigarettes. There was also no relationship between regularity of current smoking and the first experimented product. The proportion of those who smoked waterpipe in the last 30 days was 16.1% (29.9% in males, 9.9% in females, $p < 0.001$).

CONCLUSIONS: the high smoking rate is alarming and needs urgent intervention. Waterpipe smoking, the preferred choice in the first experimentation of tobacco for half of the students, appeared to feed cigarette smoking.

AIM: 127 S.aureus and 65 CoNS strains were isolated from patients noses'. To produce a biofilm ability was investigated using three different methods. Slime-positive and negative staphylococci's resistance were evaluated against different antibiotics.

MATERIAL-METHOD: Swap samples puted 7% blood agar. Staphylococcus aureus and coagulase-negative staphylococci

(CoNS) isolates biofilm produced ability were investigated using Congo Red Agar (CRA), microplates (MP) and Standard Tube (ST) methods. In addition to that, presence of antibiotic resistance of the staphylococcal isolates

are determined agar disc diffusion method. RESULTS: The rate of biofilm producing Staphylococcus spp strains was found to be 72.4%, 67.7%, and 62.9%,

with CRA, MP, and ST tests. There was no significant relationship among the tests ($p>0.05$). In addition, antibiotic

resistance of Staphylococcus spp. against various antibiotics was also determined by the agar disk diffusion

method. Resistance rates of biofilm positive (BP) Staphylococcus spp for penicilin G, ampicilin,

amocycilin/clavulanic acid, tetracyclin, eritromycin, gentamycin, and enrofloxacin 71.7%, 69.7%, 6.2%, 20.7%,

21.4%, 1.4%, and 0.7%, respectively. Resistance rates of biofilm negative (BN) spp for 42.6%, 23.4%, 4.3%, 14.9%,

19.1%, 0.0%, 0.0% respectively. All Staphylococcus isolates were found to be susceptible to vancomycin and

teicoplanin. Although BP strains antibiotic resistance rates were observed higher than BN strains. But resistance

rates were not found statistically significant ($p>0.05$).

DISCUSSION: CRA is the reliability and specificity method to determine Staphylococcus spp. biofilm produce ability.

Scientific Studies Performed in The Field of Family Medicine in Turkey: Evaluation of The National Congresses

Hüseyin Üçer¹, Yaşar Koşar¹, Soner Ölmez², Celal Kuş¹, Hamit Sırrı Keten³

¹Kahramanmaraş Sutcu Imam University, Department of Family Medicine, Kahramanmaraş

²Samsat Family Health Center, Adiyaman

³Kurtul Family Health Center, Kahramanmaraş

BACKGROUND & AIM: In this study was aimed to examine the distribution of articles according to issues done in the National Congresses of Family Medicine.

METHOD: For the last five years of the study (9, 10, 11, 12 and 13th National Congress of Family Medicine) published abstracts and dialogues were included. Due to majority in the dialogue abstracts "consult the specialist" platform were categorized separately.

Panels, workshops, and discussion sessions included speakers and topics were discussed "other studies" in the title. The courses were not taken into evaluation because of the more than one trainer. Abstracts were assessed according to presentation of, multidisciplinary, type of study, and subjects. Title and key words were taken into account in the determination of the issues.

The topics were obtained from abstracts located in report submission web pages. The data were analyzed by using SPSS 20.0 software.

RESULTS: 1278 paper were included in this study. Papers 948 (74.2%) were poster presentation, 188 (14.7%) were oral presentation, 32 (2.5%) to consult specialist, and 110 (8.6%) were the other speech summaries. Only 799 studies (62.5%) while in the field of family medicine, 81 (6.3%) different areas, and 398 (31.1%) were in the form of common study with family medicine.

Poster and oral abstracts of 188 (14.7%) were consist of case reports. Abstracts were examined by subject were

determined most research (n=212, 16.6%) and least ethical issues (n=12, 0.9%).

CONCLUSIONS: With its young and dynamic structure of our speciality of Family Medicine is able to practice in many different fields.

It is remarkable that there are few studies on ethical and abuse&violence issues. Scientific practices needs to be done on different topics in consideration of the discipline characteristics of the specialty of Family Medicine.

Evaluation of the Level of Knowledge, Attitudes, and Behavior toward Hypertension in Patients Presenting to the Tertiary Health Care Facility (Medical Faculty Hospital)

Hamit Sırrı Keten¹, Numan Güvenç², Ümit Aslan², Soner Ölmez³, Mustafa Çelik²

¹Department of Family Medicine, Kurtul Family Health Center, Kahramanmaraş, Turkey

²Department of Family Medicine, Medical Faculty, Kahramanmaraş Sutcu Imam University, Kahramanmaraş, Turkey

³Department of Family Medicine, Samsat Family Health Center, Adıyaman, Turkey

BACKGROUND: Hypertension is an important risk factor of the leading causes of preventable deaths in the world. Hypertension is an important public health concern considering its worldwide prevalence and co-occurrence with other comorbid conditions and risk factors. The aim of the present study was to evaluate the level of knowledge, attitudes, and behavior toward hypertension in patients presenting to a tertiary health care facility (Medical Faculty Hospital).

METHOD: The study included 90 subjects, who presented to the outpatient clinics at Kahramanmaraş Sütçü İmam University Faculty of Medicine for any reason between April 5, 2015 and June 17, 2015. A questionnaire containing questions about sociodemographic features and assessing the level of knowledge hypertension was administered using the face-to-face interview technique.

RESULTS: Of the participants, 69 (76.7%) were males and 21 (23.3%) were females, and the mean age was 40.97±17.24 years (min=18, max=86). Of participants, 36 (40%) reported a chronic illness and nine (10%) reported previous diagnosis of hypertension. Of the participants, 24 (26.7%) were smokers and 18 (20.0%) were using smokeless tobacco. Of these subjects, 53 (58.9%) reported that they knew the normal ranges of blood pressure and 37 (41.1%) reported that they did not know the normal ranges of blood pressure. Of the participants, eight (8.9%) responded, "a few times a week", 20 (22.2%) responded, "a few times a month", 33 (36.7%) responded, "a few times a year", and 29 (32.2%) responded, "never" to the question, "How often do you have your blood pressure measured?" Of the patients with hypertension, two (20%) reported regular attendance to control visits at the hospital.

CONCLUSION: The present study showed a considerable lack of knowledge about hypertension in patients presenting to the tertiary health care facility (Medical Faculty Hospital). It is of great importance to develop preventive health policies for hypertension.

Knowledge and Attitudes of Term I-II-III Students of Dumlupınar University School of Medicine Towards Organ Donation

Yasemin Korkut, Miyase Orhan

Department of Family Medicine, Dumlupınar University, Kütahya, Turkey

AİM: Although, information and education about the importance of organ donation and transplantation were made through all channels of communication in our country, it is observed that behavioral development of society on this issue is limited. The aims of this study are examining knowledge and attitudes of students of school of medicine towards organ donation and investigate the impact of getting closer to be a doctor on these attitudes and behaviors. **METHODS:** Data 2014-2015 academic year are registered in Dumlupınar University School of Medicine and the 115 medical schools in the first three years of accepting students to participate. The study was obtained dordurularak 6-item questionnaire.

RESULTS: Information about organ donation with 67.8% of students say they receive through television and the Internet, only 1.7% of the family physicians, while 17.6% had received information from teachers at the school. 44.3% of students thought to organ donation, organs did not forgiving them. Students from 76 people (63.9%) said they saw the most reliable in the university hospitals in organ donation. 5.2% of respondents thought that organ donation is given to our country, 52.1% said that people should be educated about it. The most preferred as the slogan 'survival chances, even if you have the chance to live' was. Medical faculty of knowledge and attitudes about organ donation of students overall period III and knowledge level of the students is higher and closer to being a physician in student increases both attitudes were found to be changing in a positive direction.

INTRODUCTION: The purpose of this study to measure the knowledge of mothers about feeding babies 0-2 years and to determine what can be done as a primary care for incomplete issues.

MATERIAL-METHOD: This descriptive study, a total of 250 mothers with babies 0-2 years were included who applied Family Health Centers in the different provinces of Turkey for various reasons. However, eight babies were excluded from the study because of missing data. Mothers in the study, given a questionnaire consisting of 37 questions and sociodemographic characteristics, breastfeeding, additional nutrients and assessing the knowledge of mothers on this topic and infants' height-weight measurements were made. The data obtained from this study assessed using SPSS 16.0, descriptive analysis and chi-square test were used for statistical analysis and $P < 0.05$ was considered statistically significant.

RESULTS: 242 mothers' average age was 28.93 ± 5.788 (17-46 years). 76% of mothers were housewives, 30.2% of primary school graduates. The mean age of the infants was 11.24 ± 7.261 months. 46.7% of infants were female, 53.3% were male and age distribution width varies between 24 months and 5 days. Babies' average height was 72.29 ± 10.076 ; weight was 9023.43 ± 2572.837 . 44.2% of infants were the first baby, 84.3% were breastfed within the first 1 hour. 100 babies were breastfed for 3-6 months and 40 babies' breastfeeding were cut before 6 months. 50.8% of infants fed with formula, 25.6% were initiated supplementary food before 6 months. Mothers' knowledge about breastfeeding 66.9% and information about supplementary food 62.4% were received from healthcare professionals. The difference was found maternal education between knowledge about breastfeeding, supplementary food and breastfeeding withdrawal time. No differences were found maternal

education between formula use, the use of feeding bottles, mother opinion, supplementary food starting shape and time and the infection status of the infant.

CONCLUSION: Mothers get their information about the nutrition of infants largely health care workers and in this respect primary care had major tasks where the first applicant for patients.

Family physicians views about family practice application in Kütahya

Yasemin Korkut, Kemal Tektaş

Department of Family Medicine, Dumlupınar University, Kütahya, Turkey

AİM: The aim of this study is to examine the views of family physicians working in the family practice field regarding good and problematic parts of the system.

METHODS: A cross-sectional study of the universe, Kütahya who work in the center and create 49 family physicians who agree to participate in the survey and family medicine specialist. 8-item questionnaire including questions and socio-demographic profile of our doctors surveyed were applied. The obtained data were loaded into 19 programs SPSS, descriptive statistics were used in the evaluation of the data.

RESULTS: Participants in the research, the Family Medicine system is asked to contribute to the health sector, while expressing it is quite positive returns compared to the former's 51.2% implementation of 32,6's% of the attending physician with a rate of application of family medicine patients were found to indicate that applicants are not enough. The lack of tools in the clinic for the question of whether this one is an impact of 38.7% saying yes, 4% said he disagreed. When asked in Turkey family medicine system is 55.1% in comparison with other countries of our lack too much, he said that we are closer to world standards 34.6%. Questions about whether enough is 48.9% of the number of family physicians to say that there is insufficient number of physicians also said that the idea of bringing doctors reluctant to 89.7% from abroad.

CONCLUSION: In this study, satisfaction and views on family medicine practice were asked. Knowing the expectations of family physicians in this process of change and solving the problem, it will improve the quality of service

Zoonoses at Work Again: Lyme Findings from Eastern Black Sea Region

Sibel Gök İncikli¹, Serpil Ekici¹, Mehmet Fatih İncikli², Ayşe Ertürk³, Ayşe Irem Sönmez⁴

¹Recep Tayyip Erdogan University Faculty of Medicine, Department of Family Medicine, Rize, Turkey

²Recep Tayyip Erdogan University Faculty of Medicine, Department of Radiology, Rize, Turkey

³Recep Tayyip Erdogan University Faculty of Medicine, Department of Infection Disease, Rize, Turkey

⁴Istanbul University Cerrahpaşa Faculty of Medicine, Istanbul, Turkey

PURPOSE: Diseases spreading by tick bites can be seen all over the world, they become a bigger problem. Lyme Disease (LD) is transferred to humans from infected ticks. Because Lyme Disease can imitate the symptoms of many illnesses, The Eastern Black Sea Region is suitable for ticks due to its climate and geographical conditions. In this research, the necessity of having LD as an early diagnosis in cases with different clinical findings was stressed.

MATERIALS-METHODS: 5 cases with LD diagnosis between 2009 and 2015 were retrospectively evaluated.

FINDINGS: Out of 5 cases, 1 was a man and 4 were women. The age range was between 14 and 49 (an average of 33) and patients were young to middle aged people. All of the cases worked in gardening, in rural areas. All of the 5 cases had joint pain. One case had complaints of conjunctivitis, one had complaints of paresthesia in extremities and one had complaints of loss of strength in the arm. Two of the patients were diagnosed with polyneuropathy, one with uveitis, one with Multiple Sclerosis (MS) and one with erythema chronicum migrans.

DIAGNOSIS and TREATMENT: In the blood tests of patients, *Borrelia burgdorferi* IgM and IgG were looked at. IgM came out positive in all cases. After the diagnosis, tetracycline and benzathine penicillin was prescribed for treatment.

RESULT: Due to geographical of the Eastern Black Sea Region, the possibility of seeing illnesses transferred by ticks is high. The patients usually come to the family practitioner months after the tick bite, when the findings become chronic. It is necessary to take the medical history well from each patient that visits Family Health Centers in our region. Since the awareness level of the public about ticks is low, as family practitioner we need to inform people so that we can take the necessary precautions about LD before the illness occurs.

In this study, it was examined whether the risk of development of asthma in the late phase is reduced or not in children protected with palivizumab prophylaxis against RSV infection.

This study was designed by 339 children between 2 to 5 years of age who were followed up in healthy children polyclinic from 2008 to 2011. The study group was chosen randomly and divided into three groups with equal number of patients in each group (n=113). Cases were evaluated in terms of the rate of wheezing and characteristic features. The comparisons were made among three groups, Palivizumab-treated children born preterm (group1), Palivizumab-untreated children born preterm (group2) and children born term (group3).

Rate of the question about children's experienced wheezing times was significant between groups. A significant difference was found between the groups in terms of the clinician who diagnosed the asthma. The groups were compared in terms of the mAPI positivity and significant difference was found among the groups. Group1 and group3 were different, group2 was found higher than the group1, but was similar to group3.

CONCLUSION: This study supports the benefit of administration of palivizumab to premature born children for reducing the risk of asthma development.

P-1195**The Quality of Life Difference Between Smoker and Non Smoker Rheumatoid Arthritis and Ankylosing Spondylitis Patients**

Onur Öztürk¹, Bektaş Murat Yalçın², Mustafa Ünal²

¹Atakum Community Health Center, Samsun, Turkey

²Ondokuz Mayıs University Medical School Department of Family Practice, Turkey

OBJECTIVE: We aimed to investigate the effect of smoking on the life quality of patients with Rheumatoid arthritis (RA) and Ankylosing spondylitis (AS).

MATERIALS-METHOD: Our study was carried out on 79 (54,5%) RA and 66 (45,5%) AS patients that were followed by Ondokuz Mayıs University Medical Faculty Hospital between March 2014 and July 2014. Since these patients were grouped as study (smokers) and control (non-smokers). Both of these groups were applied a questionnaire including certain demographic features, disease history, SF-36 and EQ-5D general quality of life scale. Both groups' quality of life is compared with each other.

FINDINGS: Of the 145 patients, 54,5 % (n=79) of the participants were females. The mean age of RA and RA patients was found as 49,6±12.9 years and 39.5±12,7 years (t=4,712, p<0,001). 39,2 % of the RA and 50,0% of the AS patients were active smokers. The average cigarette consumption of RA and AS patients was 17.94±14.73 and 13.03±9.50 packet/year respectively. First symptoms of disease were initiated 5 years earlier in RA and 7 years in AS patients who smoked patients compared with no smokers (Respectively t=2,214, t=1,9965, p<0,001). There was no statistical difference between the scores of SF-36, sub-groups of SF-36 and EQ-5D scale between smoker and non-smoker RA and AS patients (p>0,05).

CONCLUSION: Although we found no relation between quality of life and smoking in RA and AS patients, our study revealed that smoker AR and AS patients' initial symptoms begin much earlier compared with non-smokers. More studies needed to investigate the effects of smoking in AR and AS patients are needed.

P-1196**Research On Information and Attitude Levels of Residents For Smoking Conditions and Smoking Cessation Abilities**

Onur Öztürk¹, Gülsah Öztürk², Bahadır Yazıcıoğlu², Bektaş Murat Yalçın², Mustafa Ünal²

¹Atakum Community Health Center, Samsun, Turkey

²Department of Family Medicine, Ondokuz Mayıs University Faculty of Medicine, Samsun, Turkey

OBJECTIVE: To investigate the difference between the smoking frequency, cessation knowledge, attitudes and beliefs between internal and surgery specialty residents.

MATERIALS-METHOD: 121 internal and 30 surgery specialty residents voluntarily participated into the study. They answered a questionnaire consisting of 35 questions investigating their smoking frequency (The addiction level if they smoke), knowledge about cessation, beliefs. Their knowledge about smoking cessation is asked with 27 questions and every residents right answer about them is calculated.

FINDINGS: Smoking rate was 15,8% (n=24) and 12 (7,4%) among the residents and 33 (21,3%) of them were ex-smokers. Although 92% of the residents said that providing smoking cessation services are important only 33 (21,3%) of them were provided smoking counselling services. The mean number of the internal specialty residents had a mean of 13±0,7 (min=2, max=17) right answers while surgery residents had 9±0,6 (min=2, max=14). The internal specialty residents had more right answers compared to surgery residents (t=7,425, p=0,002). Residents who participated in our study believe that either their under graduate (72,9%) or post graduate medical training (62,9%) is satisfactory in this topic.

CONCLUSION: In order to increase their knowledge level regardless of their specialty of the resident's best methods should be investigated in their undergraduate or post graduate training curriculum about smoking cessation.

The Factors That Can Be Effective on Blood Count Values Among Women Aged 15-49 Years

Hilal Battal¹, Kenan Topal¹, Çiğdem Gereklioğlu²

¹Adana Numune Training and Research Hospital, Department of Family Medicine, Adana/Turkey

²Baskent University Medical Faculty, Department of Family Medicine, Ankara/Turkey

OBJECTIVE: Iron deficiency anemia is a frequent disease among women aged 15-49 years however its follow up and treatment are insufficient despite being a preventable health problem. In this study, we aimed to investigate the factors that could be effective on blood count values among women aged between 15-49 years, registered in our family medicine unit.

METHOD: A total of 617 women out of 951 aged between 15-49 years, whose blood counts were done were included in the study. Socio-demographic data, marital status, educational status, contraceptive methods used by the married women, gravida and number of children of the patients were recorded. In the patients whose hemoglobin value <12.0 mg/dL, the effectiveness of these factors was investigated with t-test and One Way Anova tests.

RESULTS: Mean age of the participants was 32.9±8.9 years, 159 (25.8%) were single, 458 (74.2%) were married. Of the married women, 102 (22.3%) were not using any contraceptive methods, 251 (54.8%) were using modern contraceptive methods, 72 (15.7%) were using conventional methods and 33 (7.2%) had underwent tubal ligation. According to education level of woman 170 (27.6%) had low education, 317 (51.4%) had moderate education and 130 (21.1%) had high education. Mean hemoglobin was 12.3±1.3 mg/dL (min 7.4 mg/dL, max 16.0 mg/dL). Hemoglobin values were found statistically significantly higher among singles (12.6±1.1 mg/dL) compared to married ones (12.3± 1.3 mg/dL). There was not a statistically significant difference between participants with regard to educational status (p=0.595), gravida (p=0.722), number of children (p=0.612) and contraceptive methods (p=0.244).

CONCLUSIONS: Anemia is frequent in fertile age and leads to many organic and psychological disturbances unless treated. We found Hemoglobin values lower among married women compared to single ones. It would be beneficial to evaluate married women more carefully in family medicine.

P-1198**Retrospective Assessment of Family Medicine Office Patients in Last Three Years**

Izzet Fidancı, Şükrü Ümit Eren, İsmail Arslan, Oğuz Tekin

Ankara Training and Research Hospital, Department of Family Medicine, Ankara

OBJECTIVE: It was purposed to assess the number and diagnosis of family medicine office admissions in last three years retrospectively.

METHODS: Patients, who applied to Family Medicine Department of Ankara Training and Research Hospital between 2012 and 2014, were evaluated according to the number, diagnosis and monthly distribution. All offices (Huseyingazi, Ulus, Yenimahalle, Bahcelievler district offices and Central Family Medicine Office) data were evaluated separately and totally.

RESULTS: 250 054 patients were included to our study. The number of female was higher than male for all offices and total. Patient admissions for each year were more than previous one. Although it varies the location of office, the most common health insurance was SSK. It was reported less number of patients in July and August, more number of patients in January and February. Upper respiratory infections were the most common reason for office admission(Table-1).

CONCLUSION: Upper respiratory infections, anemia and dyspepsia need to be emphasized in Family Medicine Residency Programs. In our study, comprehensive approach of discipline of family medicine's core competencies was supported by excessive number of patients who came for follow up acute and chronic diseases.

Keywords: Family Medicine, diagnosis, health insurance

COPD (Chronic Obstructive Pulmonary Disease) and Anemia

Serpil Ekici¹, Sibel Gök İncelikli¹, Aziz Gümüş²

¹Recep Tayyip Erdogan University, Department of Family Medicine, Rize,Turkey

²Recep Tayyip Erdogan University, Pulmonary Medicine Department of, Rize,Turkey

PURPOSE: COPD is a type of progressive and treatable disease that is characterized by chronic inflammatory response of lungs to harmful gases and particles. In COPD patients, anemia can be observed. In addition to accompanying illnesses, anemia can be caused by COPD itself as a systematic disease. In our research, it was aimed to determine the cooccurrence of COPD and anemia as well as draw attention to this situation which is actually preventable.

METHODS-MATERIALS: 250 male patients in the stable period over the age of 18 among all COPD patients that went to the Pulmonology Clinic at Recep Tayyip Erdoğan University Faculty of Medicine between 01.01.2015 and 01.07.2015 were determined. Hemogram values of patients in the stable period were retrospectively evaluated by scanning file archives. Staging of COPD was done in accordance with 2015 GOLD (Global Initiative for Chronic Obstructive Lung Disease) criteria (FEV1/FVC<0.7). Anemia diagnosis was given in accordance with WHO criteria. For male patients, anemia was accepted as hemoglobin (Hb) levels being <13mg/dl and haematocrit(Htc) levels being <%39.

FINDINGS: Hb<13mg/dl and Htc<%39 was determined in 96 of 250 patients. %38.4 of patients were diagnosed with anemia. While borderline Htc and Hb levels were observed in 16 patients (%6,4), in 7 patients (%2,8) values of Htc<39 Hb>13mg/dl were observed and in 4 patients (%1,6) values of Hb<13 mg/dl ve Htc>%39 were found. Those who met both criterias were assessed as anemic.

RESULT: As can be seen from our research, the cooccurrence of COPD and anemia is very common. Approximately one out of every three patients also struggle with anemia. This situation lowers patients' quality of life as well as making it difficult to deal with the illness. With the protective and rehabilitative measures taken by family practitioners, preventing this and such comorbid situations will be possible.

Turkish Family Medicine Journal Group was found in 7th Juna 2014 as a facebook social media page. Between dates 20th August 2014 and 10th July 2015 abstract of the journals were shared by yahoo mail group "Aile" twice a month on 10th and 25th days of every month. In every sharing, content of research in Turkish was shared with an internet link.

Sources were national and international. As international source(alphabetically); BMJ evidence updates, Cochrane reviews, American Academy of Family Physician(AAFP), Medscape Family Medicine, New England Journal of Family Medicine, Medpage Today's Kevin MD were used. As national sources(alphabetically); Ankara Medical Journal, Eurasia Journal of Family Medicine, Düzne University Konuralp Medical Journal, Medical Network Actual Medicine, Smyrna Medical Journal, Turkish Journal of Family Medicine and Primary Care, Turkey Family medicine Journal were used.

As a summary, shared total journal number was 329. Every month 12 at minimum, 38 at maximum, mean 27.4 articles were shared. Shared contents other than articles were more than that numbers, but we were not be able to reach the past contents because of Facebook protocols.

Seasonal influenza vaccination rate among 18-64 years adults

Münevver Tulunay, Esra Durmuş, Esra Akkan, Cenk Aypak, Süleyman Görpeliöğlü
Diskapı Training and Research Hospital

AIM: Seasonal influenza infection leads to significant morbidity and a major cause of loss of workforce among adults. Vaccination has shown to be a reliable, efficient and cost-effective measurement against seasonal influenza. The influenza vaccination is suggested to everyone ≥ 6 months by World Health Organization. The aim of the study is to determine the frequency of seasonal influenza vaccination among adults aged between 18-64 years. METHODS: The study was carried out in Family Medicine Department of Diskapı Training and Research Hospital between 01.04.2015-30.06.2015. Patients, aged between 18-64 years and agreed to participate were enrolled in this study. A questionnaire form including questions about demographic characteristics, health status and influenza vaccination were filled by the participants. Descriptive statistical analysis was performed. RESULTS: A total of 314 patients (72,3% female, 27,7% male) were included in this study. The mean age of the participants was 43.14 ± 13.0 years. Among the study population 119 (39.7%) patients had at least one chronic disease such as diabetes mellitus, coronary artery disease, asthma/COPD or rheumatic disease; 37 patients (11.1%) had two or more chronic diseases. The rate of patients who had been vaccinated against influenza was found to be 9.2%. Although there was no relationship between vaccination status and gender, education level, living area, marital status or having chronic disease ($p \geq 0.05$); there was a relationship between vaccination status and occupation ($p=0.02$); housewives and retirees were more likely to be vaccinated. The most frequent barriers against vaccination were found to be: not believing effectiveness (62,8%), being unaware of vaccination (15,4) and believes about potential side effects (13,3) respectively. The influenza vaccination was commonly recommended to the people who had been vaccinated, by their physicians (51,7%), by pharmacists (24,1%) or by media (13,7%). CONCLUSION: Our data have revealed that the frequency of influenza vaccination was low even among patients with comorbidities. Clinicians should inform people about influenza vaccination and try to increase the rates of vaccination.

Evaluation of The National Journals Published in The Field of Family Medicine

Hüseyin Üçer¹, Hamit Sırrı Keten², Celal Kuş¹, Yaşar Koşar¹

¹Kahramanmaraş Sutcu Imam University, Department of Family Medicine, Kahramanmaraş

²Kurtul Family Health Center, Kahramanmaraş

This study aimed to examine the contents of the National Family Medicine journals. The study prepared in Turkey was taken from the journal of family medicine. Journals until the last number of years from the initial date of publication was divided into their journals and investigated from the internet. Number of articles in each issues, types of texts (letter to the editor, review, case, research and other) number of authors, the first author's gender, titles and were classified according to related disciplines. The data were analyzed by using SPSS 20.0 software. Yet our study is under construction and total of 8 national journals of family medicine was reached. All the number of journals separated by years and their contents have been categorized. Just a journal (Turkish Journal of Family Medicine) for the last 5 year-data analyzed, a total of 187 data were entered to SPSS. Accordingly, the data of 71 (38.0%) original article, 28 (15.0%) review, 24 (12.8%) case, 6 (3.2%) letters to the editor and 58 (31.0%) were the other types of articles.

When looking at annual number of publication in the last 5 years the most 70 (37.4%) was published in 2013. According to their subjects the most in the field of women's health 26 (13.9%) were found. The results will be shared with when our study is completed.

Patient quality differences in the level of competencies of family physicians in Kosovo

Gazmend Bojaj¹, Fitim Skeraj², Genc Burazeri³, Katarzyna Czabanowska⁴

¹Principal Family Medicine Center, Kline, Kosovo

²University of Medicine, Tirana, Albania

³Department of International Health, School for Public Health and Primary Care (CAPHRI), Faculty of Health, Medicine and Life Sciences, Maastricht University,

⁴Faculty of Health Sciences, Jagiellonian University Medical College, Krakow, Poland

BACKGROUND: Skills and competencies of family physicians are a basic prerequisite for high-quality primary health care services. The aim of this survey was to assess urban-rural differences in the level of competencies of family physicians from patients' perspective in transitional Kosovo.

METHODS: A cross-sectional study was conducted in Kosovo in 2013 involving a nationwide sample of 1340 primary health care users aged ≥ 18 years (49% males and 51% females; overall age: 50.5 ± 17.9 years; response rate: 89%). Patients were asked to rate the level of competencies of their family physicians regarding different domains of health services. The self-administered questionnaire included 37 items. Answers for each item of the tool ranged from one ("novice" physicians) to five ("expert" physicians). An overall summary score on the level of competencies of family physicians was calculated [range: from 37 (minimal competencies) to 185 (maximal competencies)]. Demographic and socioeconomic information was also collected. General Linear Model was used to compare urban-rural differences in the overall level of competencies of family physicians.

RESULTS: Upon multivariable adjustment for demographic factors (age and sex), socioeconomic characteristics (education, income and employment), number of health visits in the past 12 months and the overall satisfaction with the quality of medical encounter, mean value of the overall summary score for the 37-item instrument was higher among rural residents compared with their urban counterparts (121 vs. 118, respectively, $P=0.008$).

CONCLUSION: Our findings from Kosovo indicate that patients in rural areas perceive a significantly higher level of competencies of their family physicians compared with patients from urban areas. Determinants of such urban-rural differences should be further explored in future studies in Albanian settings.

Keywords: competencies, family physicians, Kosovo, primary health care users, urban-rural differences.

Features of the patients evaluated at Dokuz Eylul University of Family Medicine Department, their satisfaction status and the opinions of doctors about the patient files who works in the clinics

Serkan Yavuz, Nilgun Ozcakar

Department of Family Medicine, Dokuz Eylul University, Izmir, Turkey

AIM: To determine the status of outpatients' file records of Dokuz Eylul University Faculty of Medicine (DEUFM) to the Department of Family Medicine, to evaluate the views of physicians about files and satisfaction of patients.

METHODS: Our study consists of all patients' records in our department between 30.03.2007-31.07.2011. All 2486 files were examined except 38 files unfound. The views of 23 physicians worked at clinic at least 3 months via a questionnaire by face to face interview. Volunteered 213 patients participated between 01.01.2013-30.06.2013 applied "Patient Satisfaction Survey".

RESULTS: The mean age was 33.93 ± 17.39 (min.0-max.87) and 1616(65%) were female within examined files. The first three main complaints were identified as general examination 606(17.9 %), cough 174(5.1%) and fatigue 121(3.6%). 1626(65.4%) patients had attended once, 441(17.7%) twice and 419(16.9%) were more than three. Most fulfilled part of patient history file was "medical history in 2172(87 %)" and the least was "problem list section 131(5.3%)". Among physicians' opinions about the files 14 of them (60.9 %) were working over 2 years, 7(30.4%) were 1-2 years and 2(8.7%) were less than 1 year. Physicians scored files as a mean point of 6.22 and stated that files are long (n=15), more detailed (n=14) and time-consuming (n=13). The "Patient Satisfaction" was considered high by 95.7 % and stated as "very good". Our patients said they would recommend our clinic to others.

CONCLUSION: In our clinic patient files are not at the desired level, physicians stated files were long, time-consuming and detailed; our patients have been satisfied.

Quality of care for the patients with osteoarthritis in primary care practise

Milena Tosic¹, Maja Račić², Igor Novaković³

¹Health Centre, Ugljevik, Bosnia and Herzegovina

²Faculty of Medicine Foča, East Sarajevo, Bosnia and Herzegovina

³Health Centre, Bijeljina, Bosnia and Herzegovina

Background. Osteoarthritis is one of the most common chronic diseases in Bosnia and Herzegovina, with greater prevalence in women, older people, and those with poorer socioeconomic status. Effective treatments are available, yet little is known about the quality of primary care for this disabling condition.

Aim. To measure the quality of care for patients with osteoarthritis in primary care practise, and assess variations by patient characteristics.

Methods. The retrospective observational study was conducted in eight family practices in the region of Ugljevik, Bosnia and Herzegovina. The records of all 120 patients with osteoarthritis registered with these practices were reviewed. High-quality health care was specified by fourteen quality indicators established by The Arthritis Foundation Quality Indicator Project. Logistic regression modelling assessed variations in quality by gender, age, occupation, functional status, localization and time since diagnosis.

Results. There was substantial variation in the recorded achievement of individual indicators. The percentage of patients whose records show that they received care in the form of information provision ranged from 85% to 91%. For regular assessment indicators the range was 21% to 100%, and for treatment indicators the range was 40% to 78%. Recorded achievement of quality indicators was higher in those with more severe osteoarthritis and longer time since diagnosis.

Conclusion. This study has demonstrated the feasibility of using The Arthritis Foundation Quality Indicator Project set of indicators to measure the quality of care for the patients with osteoarthritis in primary health care practise. Family practitioners should focus more on disability and pain and on giving information about treatment since these topics are often inadequately addressed. One challenge will be to provide a more proactive, patient-centered care.

P-1206**Accreditation of the Family Medicine teams at Health Centre Bijeljina**

Srdjan Mijatovic, Zlatko Maksimovic, Aleksandra Mijatovic, Ruzica Jelusic, Dijana Dukic
Health Centre Bijeljina

The accreditation process of the health care institutions is a recognized and widespread, comprehensive method for improving the health care quality in the world.

The aim of this work is to show the quality of work of 33 accredited FM teams compared to 22 unaccredited in Health Centre Bijeljina.

An analysis of work performed both by the accredited and unaccredited group was conducted during the year of 2014. The analysis included the first medical check number, control medical reviews, number of preventive medical reviews, number of curative checks, number of laboratory referrals, number of referrals for radiologic and ultra-sound medical check, and number of referrals for consultation reviews.

The first medical review number and the control medical review number showed that the accredited FM teams had had more first medical checks performed compared to the other control ones. The number of preventive medical reviews performed by FM accredited teams was in the average of 624.12 and 465.95 for the unaccredited ones, while the number of curative reviews was higher in the unaccredited group – 11,810 compared to 9,563.30 in the accredited group.

The accredited teams had significantly less laboratory referrals (651.30) compared to the unaccredited ones (1084.68). Also, a lot more analyses per patient were requested by the unaccredited FM teams.

As for analysis of the number of referrals for radiologic and ultra-sound medical reviews, the accredited teams had considerably less referrals compared to the unaccredited. The accredited teams had 926.94 referrals in

average compared to 1,329.41 for the unaccredited ones when analyzing consultative-specialist medical review referrals.

The performance analysis for the accredited and the unaccredited FM teams at Health Centre Bijeljina for the year of 2014 showed a great importance of the accreditation and significant improvement of performance quality.

P-1207

Performance efficiency indicators for Health Centre Bijeljina during the time period from 1st of January until 31st of December 2014

Ruzica Jelisic, Zlatko Maksimovic, Cedomir Radovanovic, Aleksandra Mijatovic, Srdjan Mijatovic
Health Centre Bijeljina

AIM: Aim of the work is to point out the significance of establishing the system for monitoring the performance efficiency indicators for the primary health care institutions. The final result of these activities would be improvement of the health care quality, benchmarking establishment and improvement of primary health care contracting and paying.

METHODS: By applying analytic, synthetic and statistic methods, the analysis results for the three indicators monitored at Health Centre Bijeljina during the time period from 1/1/14-31/12/14 have been presented throughout the work. The monitored indicators are: number of biochemical-laboratory diagnosis per 1,000 of insured persons, number of prescriptions per capita, and number of performed MR and CT per 1,000 of insured persons.

RESULTS: Discrepancy of the number of biochemical-laboratory diagnosis services per 1,000 insured persons compared to the average of 309.4 (defined by the Republic of Srpska Health Insurance Fund) is 5.1%. The number of prescriptions per capita is 0.2 less than the average (6.4) at Health Centre Bijeljina, and the excess has been registered in 32 health care institutions in Republic of Srpska. The number of the conducted MR per 1,000 of insured persons is 3.2 higher than the average (14.5). The number of the performed computed tomography per 1,000 insured persons is 0.1 less than the average (19.4).

CONCLUSIONS: The total cost of the services exceeding average values is around 4 % of the total agreed primary health care value for the period of one year. In order to improve the primary health care contracting and paying model, it is necessary to develop and apply the indicators for monitoring performance efficiency of the primary health care institutions.

P-1208**Monitoring patients' satisfaction at Health Centre Bijeljina**

Zlatko Maksimovic, Ruzica Jelusic, Milija Cvijetinovic, Cedomir Radovanovic, Srdjan Mijatovic
Health Centre Bijeljina

At Health Centre Bijeljina different parameters are being continuously analyzed, possible problems solved, quality of the services improved, the boundaries of the set tasks pushed, because things can be done in a better way, and only a satisfied user of the health care services secures us a leading position in the region and farther.

Aim of the work: is to show the significance of monitoring and measuring the satisfaction of health care users at Health Centre Bijeljina.

METHODS: Data, information, points of view and opinions of the service users have been gathered by applying the questionnaire method.

RESULTS: The Republic of Srpska Health Insurance Fund Bijeljina has been monitoring satisfaction of the insured at Health Centre Bijeljina. The users of the services are allowed to give a mark from 1 to 5 in the questionnaires. The total satisfaction mark in 2009 was 4.63, and 4.95 for the year of 2013.

In addition to the above mentioned questionnaire, the Republic of Srpska Agency for certification, accreditation and health care quality improvement regularly performs its own surveys among the accredited FM teams. The questionnaire addresses the issues of patients' rights and needs being respected by the FM team members, and the aim is to have 75% of the examinees answer the asked questions positively. The results obtained by processing these polls have shown that 97 % of the examinees gave positive answers in the year of 2013.

Information on satisfaction and experiences of the health care users are also obtained based on Health Centre Bijeljina yearly poll performed by the Quality Sector.

CONCLUSION: By monitoring and measuring satisfaction of the health care users at the health care institutions we obtain information based on which the quality of health care and services can be improved.

P-1209**Performance in 2014**

Nevenka Strahinja Radosavljevic

Prim dr Nevenka Radosavljevic

Background & AIM:

Analyze last year's work aimed at considering the possibility of increasing quality.

METHOD:

Retrospective analytical study of annual report.

RESULTS:

In the period 1.1 2014 - 1.1 2015 7577 was conducted visits patients, in average 43 per a day, a curative reviews is 93.8% or 7106, screening 6.2% or 471 visit.

First curative review is 2957 or 41.6%, control examinations of the chronic patients 2016 or 28.4%, short visits (prescribing medication, blood glucose monitoring, EKG) was 2133 or 30%.

From preventive examinations vaccination is 120 or 25.5%, visit of the Health Educational Work Group 6.6% or 31, 145 individual patients education or 30.7%, systematic examinations 101 or 21.5%, screening 74 or 15%.

CONCLUSION:

Unsatisfactory number of examinations check-ups, because of the workload.

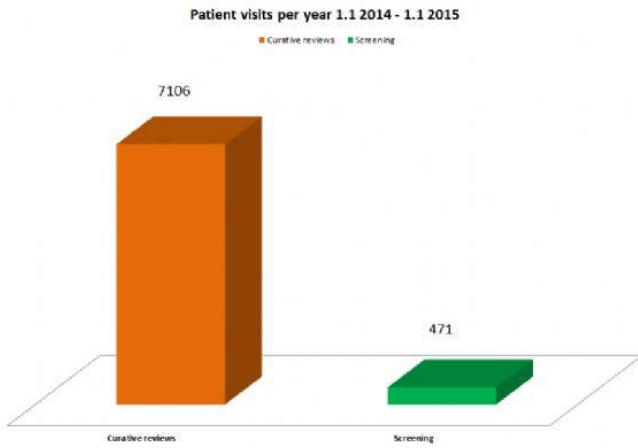

Exchange experiences and ideas to improve the quality of work.

Questions for DISCUSSION:

What is your workload and the structure of the examination?

Improving family medicine referrals to mental health services for over 75 year olds

Claire Patricia Rees¹, Debra de Silva²

¹Centre for Public Health and Primary Care, Queen Mary University, London, UK

²The Evidence Centre, UK

Background & Aim

Most western countries have an ageing population and there is a hidden burden of mental health issues amongst the elderly. Family practice has a key role to play in ensuring older people can access the support they need. One UK family practice aimed to increase identification of people aged over 75 years with depression and anxiety and improve referrals to free community mental health services.

Method

The study used a before and after design. Family doctors were surveyed about barriers to identifying and treating depression and anxiety in older people. Data were collected about the prevalence of anxiety and depression and referral rates.

A drop-in advice session for patients was run in partnership with a local charity and family doctors and practice nurses attended a training session about mental health in older people. A resource pack was developed for family doctors, including screening tools for depression and anxiety and a leaflet to give patients about local services to improve mental wellbeing. The programme is running from October 2014 to May 2015.

Results

The practice has 580 registered patients aged over 75 years, 61 of whom have a recorded diagnosis of anxiety or depression (11%). In the year before the interventions, only seven people were referred for help (1% of the entire older group and 11% of those with a known diagnosis). In just five months after project began, a further seven people were referred, thus doubling the referral rate (23% of those with a diagnosis).

Conclusion

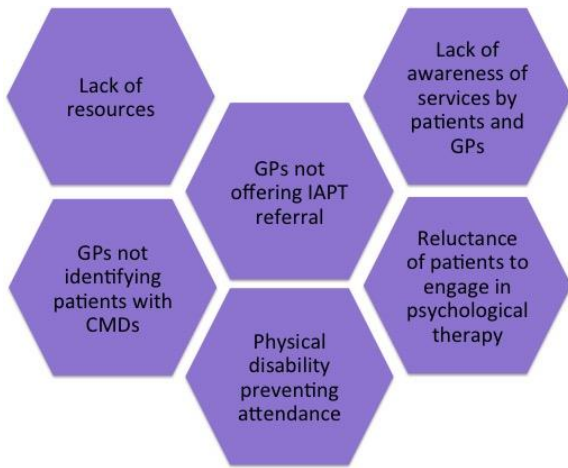

This pilot study shows that simple changes can raise awareness in family practice about mental health issues in the elderly and help more people get the support they need. It also shows that it is possible for family practice to take a proactive approach to improvement, strengthening service delivery.

Quality of life after aorto-iliac by-pass surgery

Nurver Turfaner Sipahioğlu¹, Murat Kurul¹, Ece Sivrel Uzun¹, Tuğba Durdu¹, Caner Arslan², Hasan Tüzün²

¹Istanbul University, Cerrahpasa Medical Faculty, Department of Family Medicine

²Istanbul University, Cerrahpasa Medical Faculty, Department of Cardiovascular Surgery

AIM: The aim of this study is to assess the quality of life before and after aorto-iliac by-pass surgery in peripheral artery disease patients and correlate it with demographic factors, comorbidities and presenting complaints.

Materials&METHODS: Thirty patients admitted to the cardiovascular surgery department for aorto-iliac by-pass surgery were recruited in the study. All of them were male gender except one patient. Their mean age was 59±9.93 years. SF-36 was applied to the patients in one week before surgery and after 2 months. A questionnaire involving demographic data and information about the disease was also given to the patients.

RESULTS: In SF-36 quality of life questionnaire, physical role restriction (p=0.012) and pain (p=0.020) scores were significantly decreased post-operatively.

Education level was negatively related with post-operative pain (p=0.036). Pre-operative pain was positively related with BMI (p=0.038).

Receiving education about illness (p=0.032) and the source of information (p=0.030) affects pre-operative general health.

DISCUSSION: Aorto-iliac by-pass surgery improves physical role restriction and pain caused by peripheral arterial disease after two months. Low education level causes an increase in post-operative pain.

Keywords: Quality of life, SF-36, aorto-iliac bypass, peripheral artery disease

P-1212

Quality in Italian General Medicine: a mixed-method research approach to study how to improve GP-work quality

Alessandro Mereu¹, Stefano Giovannoni¹, Alessandro Bussotti²

¹Specific Training on General Medicine, Tuscany Region, Florence, Italy

²Continuity of care Agency, Careggi Hospital, Florence, Italy

The Italian GP-work needs fundamental improvement in order to face new important transformations (epi-demographic, organizational, economic straits, medicalization of life, healthcare expenditure growth) which could make obsolete the traditional activities.

The aim is to answer the research question "How to improve GP work-quality?" with a fieldwork research where young and senior GPs can acknowledge the actual quality level and imagine quality improvement strategies.

Method

A mixed-method approach is the best option to examine the perceived quality of GP activities in order to collect relevant quantitative data about GP-workload in daily life, and meanings of what is quality for GPs.

The study design consists of 6 interviews with senior-GP and 3 focus groups with 6 young-GPs each group.

The results of this qualitative section will contribute (concurrently with a bibliographic research and the collaboration with an anthropologist) to build a semi-structured questionnaire, about quality and quantity GP work indicators, consigned to 30 senior-GP and to design quality improvement activities to settle in actual GP work-

system.

The research is based in Tuscany. All of the samples are gender and geographically balanced.

Interviews and focus groups will set on April-June 2015; semistructured questionnaire will set on June-August 2015; result analysis will set in September 2015; quality improvement argumentation will set in October 2015.

Results

Results are not available at this time. Interview and focus group tracks are ready.

The results will be statistical data and qualitative information.

Conclusions

In order to give back a complex scenario about quality and quality improvement needs, is important to use, as key-informers, the GPs and not only external observers.

GPs could give important contribute about how to design the future PHC delivery-system because they are deeply involved. The mixed-method research approach could be significant to give relevant information in the PHC work, not just numbers but also meanings.

Keywords: Quality Improvements, Mixed-method Research, General Medicine

P-1213

We really have time in our practice for the digital age?

Hector Leonardo Lugo Ramos, Juan Jesus Rodriguez Vallejo, Jose Maria Fernandez Gonzalez, Pedro Guijo Gonzales
La Granja Health centre, Jerez de la Frontera, Cadiz, Spain.

OBJETIVES

Evaluate the use and management of a "digital tool" for primary care to receive results of laboratory tests requested.

MATERIALS AND METHODS

Survey of all physicians in two health centers in the same health area, questioning on a new digital tool that generates messages when accessing the daily list of patients, showing analytical results previously requested and generating alert symbols in the altered tests.

It consists of 10 questions(9 multiple choice,1 open)seeking information on knowledge of digital tools, when and how it is used, utility versus query time and influence in number of applications. An item in the end self-assessment of the survey and a space to suggest research topics. Data analyzed by SPSSv.21

RESULTS

23 doctors are surveyed, everyone knows the digital tool, 34.8% use it daily, 21.7% several days a month and 26.1% never used. 52.6% open messages with alert symbol, 47.4% open all messages, 63.2% calls the patient with abnormal results, 31.6% expect to go on their own and 8.7% do nothing. 78.9% Rate digital useful tool, 21.1% did not.

To use, "84.2% consider it a necessary one additional time in medical practice", 17.4% believe no longer useful. Who consider additional time in medical practice 4.3% consider 5-10 minutes, 47.8% 10-15 minutes, 36.4% 15-20 minutes, and 13% more than 20 minutes.

None requests further tests from the use of the portal. Most (84.2%) believed that these surveys help manage medical practice.

The final opinions suggest researching emergencies in primary care and patient hyper-frequenter.

CONCLUSIONS

Digital tools in medical practice are necessary and useful.

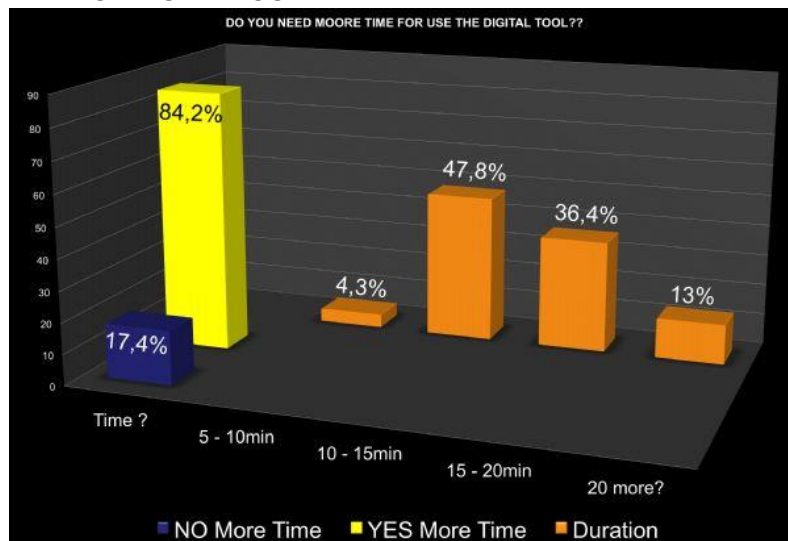

Alerts on digital tool accelerate the detection of altered tests.

It is considered necessary additional time in medical practice to use them.

The number of applications did not increase with the use of the portal.

Infant mortality as sentinel event for improving the quality of healthcare provided by Family Health Program

Selma Cristina Franco¹, Maria Volpato Kropiwicz², Terezinha Hillesheim², Fatima Mucha², Débora Galli Morais², Viviane Korovski²

¹Health and Environment Master, University of the Region of Joinville - UNIVILLE, Joinville, Brazil

²Secretary of Health, Joinville, Brazil

Background and AIM: Infant mortality (IM) is considered a sentinel event that may express quality of healthcare. This paper aims to describe the profile of IM occurred in areas assisted by Family Health Program and to report the analysis and recommendations of an Infant Mortality Prevention Committee (IMPC) regarding improvement of healthcare.

METHOD: Retrospective study conducted in a municipality in the south of Brazil with data collected through interviews with the families of children who died between 2010 and 2014, medical reports and death certificates. **RESULTS:** In the period, 316 infants died in the municipality, 119 of them living in areas assisted by Family Health Program. Infant mortality index was 8.2 per 1,000 live births and the neonatal component was 4.9. Mothers' characteristics showed high percentage of adolescents (22.7%) and insufficient number of prenatal care visits (63.7%). Newborn babies were mostly premature (63.9%) with low birth weight (68.9%). Most of the deaths occurred in State-run hospitals (76.5%) due to perinatal causes (42%) and malformation (28.6%). Investigation of deaths conducted by IMPC showed problems in health care provided by Family Health Program (18.5%), Neonatal Intensive Care Unit (10.1%) and Prenatal (8.4%). According to SEADE criteria, 79.8% of the deaths could have been avoided by preventive measures, early diagnosis and prompt treatment (42.9%). IMPC performed correction in national databases (37% of the deaths), forwarded written responses and orientations to Family Health Teams (17.6%) and discussed healthcare problems with professionals (11.8%).

CONCLUSIONS: Most of infant deaths (79.8%) were preventable. Knowledge on the profile of deaths and

investigation performed by IMPC indicate there is possibility for improvement in the quality of healthcare delivered at Family Health Program and generate useful data for local planning.

P-1215

Can general practices read a point-of-care urine culture? General practices' ability to interpret the Flexicult™ using an online multiple-choice-test

Anne Holm, Volkert Siersma, Lars Bjerrum

The Research Unit for General Practice and Section of General Practice, Department of Public Health, University of Copenhagen

BACKGROUND & AIM

Urine culture and susceptibility testing in general practice is common in Denmark. The Flexicult™ ssi Urinary kit, a chromogene agar for urine culture and susceptibility testing, has been validated and ongoing trials are testing it clinically. The ID Flexicult™ is a chromogene agar for culture only. The aim of this study was to investigate if general practices were able to read and interpret the two tests and to generate hypothesis about factors influencing test performance.

METHOD

General practices participating in a randomized controlled trial were told to complete an online multiple-choice-test. The test consisted of ten photos, five of the Flexicult™ ssi Urinary kit and five of ID Flexicult™. For each photo, the respondents should answer if they found significant growth or not. Two photos had no significant growth and eight had significant growth.

RESULTS

17 practices answered the test with 37 respondents in total. The number of respondents per practice ranged 1-9. On average, 89% were correctly answered. Growth was correctly identified in 90% of cases, no growth in 85%. The probability of answering correctly was tested in a logistic regression model including photo, respondent background (owner, employed doctor or other staff) and type of clinic as covariates, and GEE methods to adjust for multiple answers per respondent. The respondents' background was associated to answering correctly, but the difference was not statistically significant. Some photos turned out more difficult to answer correctly than others and the difference was close to statistically significant ($P < 0.07$).

CONCLUSIONS

In this small online-test, general practices performed well in reading the Flexicult™ both with and without susceptibility testing. Photo-based online tests could be used for quality control in primary care, but photo difficulty and respondent background has to be taken into account when designing and evaluating the test.

Patient-related continuity of care has deteriorated markedly in general practice in Finland from 1997 to 2012

Risto Raivio¹, Kari Mattila², Tuula Arvonen³, Seppo Voutilainen³

¹Primary Health Care Unit, Joint Authority for Päijät-Häme Social and Health Care Group, Finland

²School of Medicine, Department of General Practice, University of Tampere, Finland

³General Practitioner (retiree), Finland

Background and Aim

Continuity is an essential aspect of primary care quality. We here assessed patient-related continuity of care in general practice in the City of Oulu in Northern Finland. We also studied the relationship between the patient indicators and the continuity of care.

Method

We conducted a follow-up questionnaire survey in 1997 and 1999, and from 2002 to 2012 every second year among patients attending the Oulu health care centres. We used the questionnaire "The quality of health centre care: patients' view" developed in the National Research and Development Centre for Welfare and Health and subsequently adapted by the National Institute of Welfare and Health of Finland. Continuity was assessed by the question: "When visiting the health centre, do you usually see the same doctor?" The relationship between the indicators of patients and the continuity of care was analyzed in the questionnaires in 2010 and 2012.

Results

Continuity of care in general practice in Oulu decreased from 92 % to 30 % from the year 1999 to 2012. During the years 2010 and 2012 continuity of care was 41 % among patients 60 years or more and 37% among those who attending consultations more than six times. Continuity of care was realized slightly better in the elderly age-group and in the frequent attenders' group than in other groups. There was no relationship between gender or education and continuity of care.

Conclusions

Patient-related continuity of care deteriorated significantly in general practice in Oulu health care centres in Northern Finland from 1997 to 2012.

TITLE Internal Communication Plan

Anna Forcada Arcarons, Laura Almendros Plana, Josefa Soler Arau, Silvia Altimiras Rovira, Engracia Costa Atienza, Alícia Díaz Pilco

institut català de la salut

BACKGROUND

Internal communication is the basis of media organizations. It is addressed to the internal customer and comes in response to the needs of companies to motivate his team.

There is no good corporate communication (neither external) without good internal communication.

AIM

- Improve communication between professionals and promoting participation
- Improve efficiency and participation of people of the team
- Improving relations between different levels
- To promote the sense of belonging to the organization
- Reduction of collateral information
- Improve the work environment

METHODOLOGY

Descendant communication: goes from one superior hierarchical level to a lower one. Provides information to people about what to do. Expected misunderstandings and build trust with respect to superiors. The tools are the ICS portal, GTCC intranet, SAP Management advices, EAP meetings, meetings for strata, team leaders meetings, corporate email, space R (located on each computer), information panel in the rest room.

Ascendant communication: It originates in a lower hierarchical level and goes to the top. Reveals the working environment of workers and stimulates creativity. Increase commitment to the organization. The tools are SAP Management advices, EAP meetings, meetings for strata, team leaders meetings, suggestions and corporate email inbox.

Horizontal communication: between professionals from different units of the same level or between components of a working group. Promotes teamwork. The tools are the clinical sessions, EAP meetings, corporate email, R space, information panel in the rest room.

RESULTS AND CONCLUSIONS

The communication plan allows us to improve the information to all levels of the organization, optimizing media and channels of communication within the team, create a good climate for communication and a sense of belonging to a tea

How we manage the Ramadan in the Primary Healthcare centre of Manlleu

Anna Forcada Arcarons, Silvia Altimiras Rovira, Lluisa Barranco Cozar, Maria Callis Privat, Anna Maria Garcia Moreno, Carla Hernandez Bacardit, Marta Roca Lafont, Alícia Díaz Pilco

institut català de la salut

BACKGROUND

The month of Ramadan is the 9th month of the Muslim calendar and has 30 days. It is one of the five pillars of Islam. From sunrise to sunset can not drink or eat, or smoke, or sexual relations.

Are excluded, the sick, pregnant women, breastfeeding women, young children, the elderly or who might harm their health. This protocol is designed for all Primary Health Care team of Manlleu for good coordination between public health, the correct use of health services and patient safety practitioner of Ramadan.

AIMS

- To program tests and visits of the users effectively.
- Optimize health resources with the right information and a prudent time in advance.

METHODOLOGY

Annually information through Iman of the community to know which is the month of Ramadan.

Each group made some specific actions:

- Doctors and Nursing: will assess if some analytics and / or tests can be postponed until after the month of Ramadan. Insist on the importance of continuing with diet and medication according to the user's pathology.
- Administrative: inform the user of practicing Ramadan fasting compulsory whether to do some testing. Postpone the test unless it is urgent.
- Dentistry: will postpone control visits

Users requesting an urgent visit, the health professional will inform the attending high probability that prescribes medication may interfere with Ramadan and try to adapt the pattern of medication.

RESULTS

During the month of Ramadan in 2013 there was a 13.39% of Ramadan practitioners who could not realize the analysis because they had not applied fasting.

During the month of Ramadan in 2014, when the protocol was applied the incidents were reduced at 3.16 %.

CONCLUSIONS

Ramadan protocol applied in our center has been very efficient.

Keywords: Ramadan, primary health care, resources optimization

General practitioners' views on the integration of a non-dispensing pharmacist into general practice

Vivianne Sloeserwijn¹, Antoinette De Bont², Dorien Zwart¹, Marcel Bouvy³, Han De Gier⁴, Niek De Wit¹, Anne Leendertse¹

¹Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht, The Netherlands

²The Institute of Health Policy and Management, Erasmus University, Rotterdam, The Netherlands

³Department of Pharmaceutical Sciences, Utrecht University, Utrecht, The Netherlands

⁴Department of Pharmacotherapy and Pharmaceutical Care, University of Groningen, Groningen, The Netherlands

BACKGROUND & AIM: Risk factors for medication-related problems are age, polypharmacy and multimorbidity. Given the ageing of the population, the population at risk will grow in near future. Hence, new strategies are needed to improve the quality of pharmacotherapy in clinical practice. There is growing support to expand the role of pharmacists in the process of medication management, for example by integration of a non-dispensing pharmacist (NDP) in a general practice. The aim of this study is to describe general practitioners' (GPs) perspectives on the integration of a NDP in general practice.

METHOD: Semi-structured interviews with ten GPs were conducted 6 months after NDPs started working in their practices, to identify GPs' views on the integration of a NDP in primary care and their current experiences. At 12 months additional in-depth interviews were conducted. Interviews were audio-taped and transcribed verbatim. NVivo was used to perform qualitative analyses.

RESULTS: Interviews after six months showed that most GPs agreed on the initial need for improvement of provided pharmaceutical care. They collectively agreed that a NDP was an appropriate professional to assist with medication management. Required competencies and various roles for the NDPs were described. Overall, GPs' perspectives on the integration of a NDP were positive. GPs experienced an increased medication safety as a consequence of better collaboration in medication management. Also several barriers – mainly logistic – were reported. Results of the in-depth interviews after 12 months, will be available and presented at the conference.

CONCLUSIONS: After six months, GPs' perspectives on the integration of NDPs are positive. All GPs experienced an increased medication safety.

A mixed-methods evaluation of emerging large-scale family medicine organisations in England

Natasha Curry, Alisha Davies, Kushal Barai, Claire Currie, Lucia Kossarova, Stephanie Kumpunen, Niraj Patel, [Luisa Pettigrew](#), Rebecca Rosen

Nuffield Trust

BACKGROUND & AIM: The international trend towards federating family doctors into large-scale organisations has attracted significant attention in England, but the impact of these organisations on outcomes (for patients, populations and staff) relative to traditional models of family medicine remains unevaluated. This two-year study examines the aims, benefits and challenges to delivering high-quality care in emerging large-scale family medicine organisations.

METHOD: A mixed-methods approach was used to examine the evolution of 12 large-scale family medicine organisations, including four in-depth case studies. Document analysis, semi-structured interviews and observations were undertaken to understand organisations' aims and structures, motivations for forming, and factors affecting development. Time trends in nationally available practice-level quality indicators were compared between and within organisations, and to national benchmarks.

RESULTS: Interim case study results reveal that the principal aims for organisations' formation included improving care, ensuring capacity and sustainability, and bidding for large service contracts. Many clinical governance and quality improvement systems and processes were in place or under development across organisations, but attributing changes in quality to particular quality initiatives or organisational forms requires additional analysis.

CONCLUSIONS: Lessons identified in the organisations' formation are of significant importance given the national and international drive to implement new models of large-scale family medicine. It may be too early to identify changes in quality of care, but further analysis of the in-depth case studies will enable examination of more specific quality metrics and determine whether new models provide benefits relative to 'traditional practice'.

Usage of an unobtrusive decision support system in general practice

Derk L Arts¹, Stephanie Medlock², Saeid Eslami², Ameen Abu Hanna², Henk C Van Weert¹

¹Department of general practice, Academic Medical Center, Amsterdam, The Netherlands

²Department of medical informatics, Academic Medical Center, Amsterdam, The Netherlands

Aim and PURPOSE: Adherence to clinical guidelines is reported to be as low as 50%. Studies have shown decision support systems can improve guideline adherence. We implemented a clinical decision support system to improve guideline adherence among general practitioners (GPs). We report on usage of the system over time.

METHODS: We developed a novel decision support system that displayed a list with pending recommendations for the on-screen medical record in real time. Recommendations could be opened for a description or ignored.

Usage of the system was investigated in a randomized controlled trial by tracking mouse movement and clicks.

RESULTS: A recommendation was triggered 336141 times, resulting in an average of 55 recommendations per GP per day. Usage, defined as [opened recommendations] / [total recommendations], was on average 0.012%.

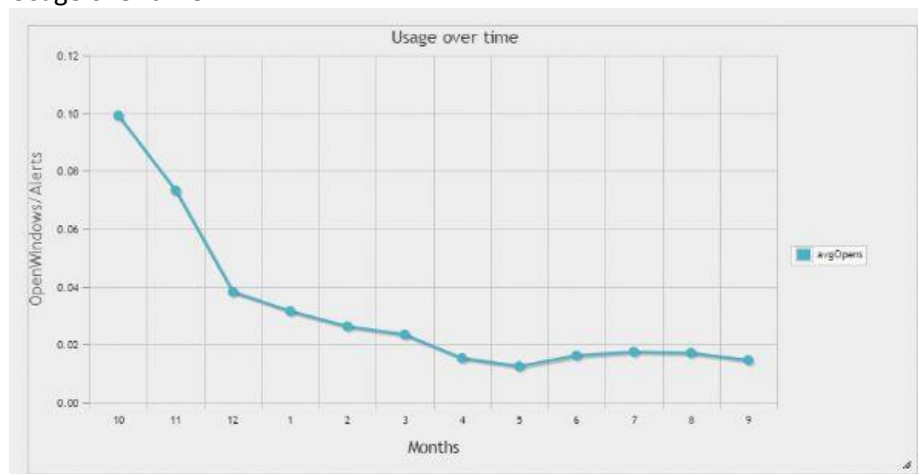

Overall usage over time declined with an average usage of 9.9% during the first month and 1.7% after 9 months.

Usage per GP ranged from 0% to 8%. Recommendations with the highest usage pertained to fall and stroke prevention while those with lowest usage pertained to diabetes care and benzodiazepine usage.

CONCLUSION: We performed a randomized controlled trial to study the usage of a clinical decision support system in general practice. Usage of the system was low and decreased over time. There were big differences in usage between GPs and usage depended heavily on recommendation content.

Improving pharmaceutical care by integration of a non-dispensing clinical pharmacist in Dutch primary healthcare: a Q-study on the debate

Ankie Hazen¹, Vivianne Sloeserwij¹, Dorien Zwart¹, Marcel Bouvy², Han De Gier³, Niek De Wit¹, Anne Leendertse¹, Antoinette De Bont⁴

¹Julius Center For Health Sciences And Primary Care, University Medical Center Utrecht, The Netherlands

²Department of Pharmaceutical Sciences, Utrecht University, The Netherlands

³Pharmacotherapy and Pharmaceutical Care, University of Groningen, The Netherlands

⁴The Institute of Health Policy & Management, Erasmus University Rotterdam, The Netherlands

Background & AIM: Lately, the role of pharmacists in the Netherlands is changing: instead of mainly organising and monitoring logistic processes (e.g. dispensing the right medication to the right patient), the focus is increasingly on providing patient care. The most profound example of this shift in scope is the integration of a non-dispensing pharmacist in a primary care team. Opinions on these developments differ widely. The aim of this study is to provide insight in differences and similarities between general practitioners, pharmacists and external stake holders in their opinions on integration of a pharmacist in primary healthcare.

METHOD: Based upon an extensive literature search and six semi-structured interviews with healthcare professionals, 37 statements on pharmaceutical patient care in the Netherlands were formulated. In a period of five months, general practitioners, pharmacists and external stake holders in primary care were invited to rank-order these 37 statements and to explain the order chosen. Groups of participants with different or shared mindsets were identified using by-person-factor analysis.

RESULTS: This study identifies the degree of consensus on specific statements about a non-dispensing pharmacist integrated in primary care. Preliminary results showed that no consensus existed on the need for pharmacists to fully shift their focus from dispensing drugs to providing pharmaceutical patient care, nor on whether GPs' knowledge about pharmacotherapy is sufficient or not. Consensus existed on the importance of having access to patient information in order to improve quality of pharmaceutical patient care. Further results will be available and presented at the conference.

CONCLUSIONS: Integration of a non-dispensing pharmacist in primary care is controversial.

Keywords: general practitioner, pharmacist, pharmacotherapy

Creating a Simple and Comprehensive Primary Care Library Catalogue using Referencing Resources

Adam Azzam, Soleman Begg

St John's Hill Surgery - Begg Practice

This poster disseminates the practical experiences of using online tools and current referencing applications to create a comprehensive and searchable library catalogue. With a critique of currently available tools including: Google Scholar, End Note, Reference Manager and ProCite.

This poster focuses upon the organisational aspect of primary care.

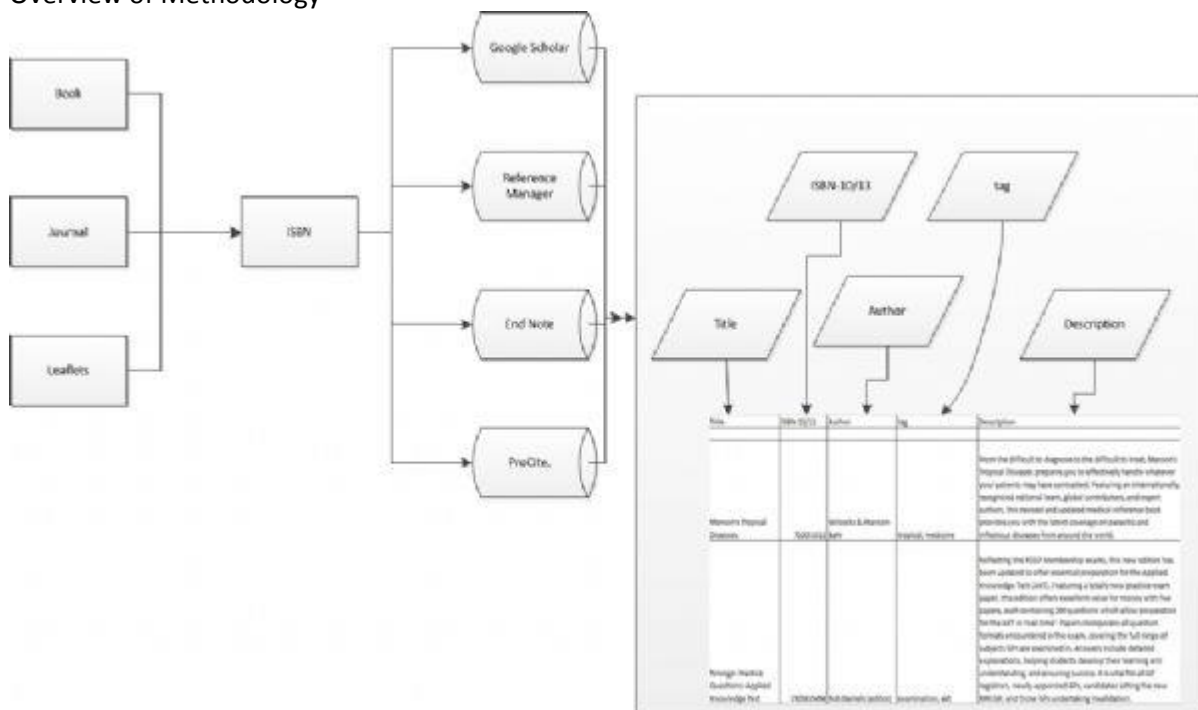

PURPOSE: To encourage the use and accessibility of the contents of libraries within Primary Care Centres.

METHOD: Allowing accurate and quick indexing and tracking of the books. Simultaneously increasing accessibility of these resources to the staff members within a surgery, including trainees. As well as reducing loss of the books.

This will also enable the reader to decide upon their preferred method of completing. With suggestions for how to use of developing technology in the future (eg mobile devices).

Ensuring quality management in drug prescription at Primary Care

Gemma Puig Ponsico, Isabel Rosich Martí, Mònica Torremorell Núñez, Esther Diaz Salcedo, Cristina Gallardo Sánchez, Margarita Navarro Pujol, Mar Pérez Herrera, Herminia Palacín Piquero, Josep Maria Vidal Royo, Miquel Perona Pagán

SAP Garraf, Institut Català de la Salut, Catalonia, Spain

Background and Aim

A computerized module integrated into the medical patient record called Self-audit supports physicians in reviewing their prescription. Self-audit allows the physician to perform a self-assessment in the drug prescriptions process. It also allows running searches in the database of ECAP (the medical record software) in those patients who meet clinical conditions relating to the use of drugs that may be improved and providing alternatives easy to apply.

Improvements can be made in different areas of the drug prescription (safety, effectiveness and efficiency). In this experience we prioritized safety considering its implication on the patient healthcare.

The aim of the study is to analyze the results of the review of patients with security incidents in prescription through the self-audit tool

Method

Intervention study conducted in before-after in 5 primary healthcare teams in the Area of Primary Care Garraf that gives health coverage to a population of 132.634 patients. The impact is measured as assessment/reduction of patients that Self-audit identifies incidents with security alerts, duplication of medication and polimedication during the year 2014.

Self-audit detects: 1.Security alerts communicated by the Spanish Agency for Medicines and prioritized by their clinical relevance (Identification of patients with contraindications); 2. Duplications high relevance; 3.

Polimedication in patients > 65 years > 10 drugs

Results

The total number of incidents in the baseline period were: Security Alerts (61) duplicities (890) and polimedication (1273) and in the final period Security Alerts (14) duplicities (404) and polimedication (910).

The reduction in Security Alerts was a 77%, duplicities 54.61% and polimedications 28,71%.

Conclusion

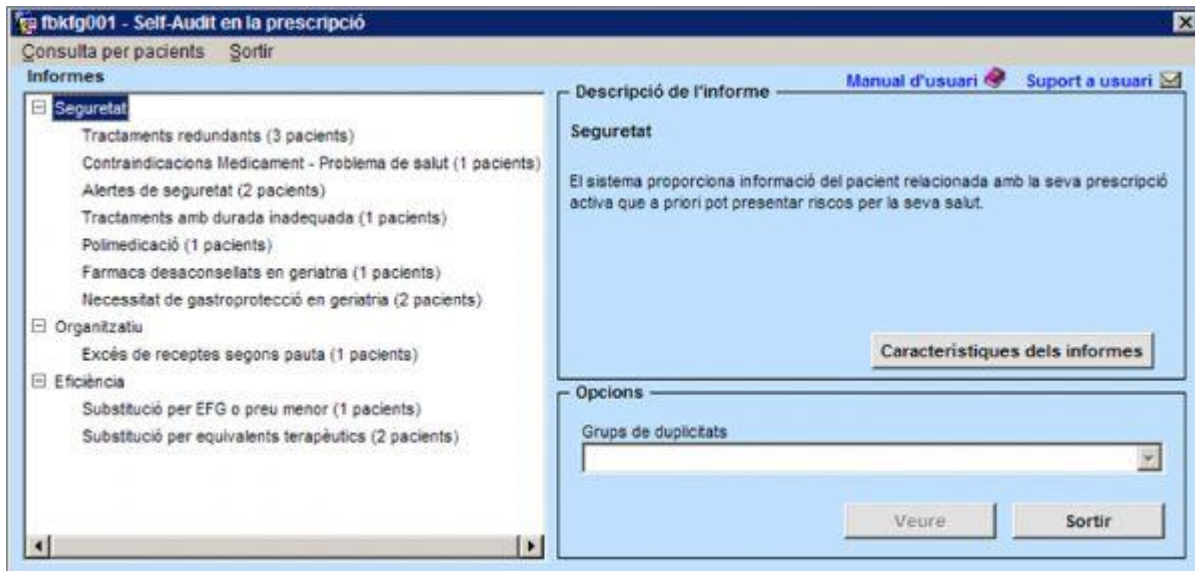

The Self-Audit tool built-in the computerized medical record allows the family doctor identify security alerts and take decisions in the patient treatment according to clinical conditions of each of them in the act of health care.

poverty and childhood

Hadiye Küçükkaragöz¹, Selbinaz Güneş²

¹DEÜ EDUCATION INSTITUTE FAMILY COUNSELING AND EDUCATION DEPARTMENT

²Family and Social Policies Minister, Social Services Department

This research is examined the effects of poverty over children between eight (8) and fifteen (15) ages in physical, cognitive, social and emotional manner. Main purpose is to identify how children, who are obligated to live in poverty, are affected by poverty. Children's thoughts, feelings and behaviors and the influence of poverty variables (age, gender, family members, education, siblings, parental education, employment, whether parent(s) dead or alive, conditions of handicapped parents, school and friendship etc.) are examined.

This study is a relational/ descriptive model and both quantitative and qualitative data collection tools are used. Population consists of poor families and theirs' children live in Buca, İzmir in 2014. Sample group 30 families and their children who are applied for monthly financial aid to Buca Social Service Department Social and Financial Support Division.

Data tools, developed by researchers, are; a) interview survey form which is constituted to determine socio-demographic and economic conditions of poor family (FSDEF), b) a semi-structured interview form for children to analyze psycho-social effects of poverty over children and (CPSIF) and c) a semi-structured interview form for mothers to examine their opinions about poverty and family development (mothers interview form family interaction), (MIFFI). The data, is evaluated with review of literature and outcomes are presented through frequency, percentage and descriptive/ content analyze.

40 % of family members that contributed to the research are primary school graduates and 36 % of the research sample is illiterate. It is concluded that 90 % of the families are supported by governmental agencies when they had a financial difficulty and 83 % of their children are not working after school in order to earn money.

Development of Clinical Practice Guideline Adaptation Strategy and Pilot Testing of Strategy

Duygu Ayhan Başer¹, Rabia Kahveci², Ilknur Yaşar⁴, Meltem Koç³, Irfan Sencan², Ismail Kasım², Adem Özkara²

¹department of family medicine, Kocaeli Deince Public Health Center, Kocaeli, Turkey

²department of family medicine, Ankara Numune Training and Research Hospital, Ankara, Turkey

³department of family medicine, Mamak Public Health Center, Ankara, Turkey

⁴department of family medicine, Yenimahalle Public Health Center, Ankara, Turkey

INTRODUCTION: The development of high quality clinical practice guidelines is very important. The clinical practice guidelines developed by using 3 methods in all over the world. In our country, guidelines are developed by de novo methods or translated directly; adaptation method don't known and used in Turkey.

Our goal with this study is to develop adaptation strategies specific to Turkey for clinical practice guidelines and to adapt the ADAPTE manual to develop this strategy.

MATERIALS-METHODS: "ADAPTE Adaptation Guideline" determined as a basis guide to develop adaptation strategies specific to our country. The ministry of health translation guidelines for primary health care was considered appropriate to the pilot study. Adaptation required areas of the selected pilot guidelines' have been identified. During the implementation of adaptation of pilot guidelines, the availability of ADAPTE' with current state was tried, the additional parameters in guidelines which should be used in the adaptation process was also determined.

FINDINGS: As a result of adaptation of ADAPTE guideline to conditions in Turkey, 2 of 24 steps rejected, 4 of them have been accepted with modification, 3 of them have been accepted with additional suggestions.

As a main result of pilot tests showed that translated guidelines required adaptation especially on diagnostical recommendations.

RESULT: The guideline adaptation is a new concept for many countries and the institution / organizations. By the adaptation of ADAPTE Adaptation Guidelines to our country, the usage of this guideline in our country will be facilitate and the information in the guidelines that will useful to audience to use and will be created in the days

ahead, will be collected in a guideline more quickly with less effort by the selection, screening, or modifying and without having to spend much material and spiritual effort as de novo methods and methods.

Quality of iron deficiency anemia diagnosis and treatment in pregnant women

Isa Maria Cruz, Ana Paula Fonseca, Márcia Filipa Soares

USF Cruz de Celas, ACeS Baixo Mondego, Coimbra, Portugal

AIM: Evaluate the quality of iron deficiency anemia diagnosis and treatment in pregnant women, according to clinical guidelines provided by the Portuguese Health Authority (NOC nº 030/2013 de 31/12/2013).

Population: Pregnant women who had an appointment at our family health unit from 18/09/2014 to 18/02/2015 (first assessment period). The second assessment period is scheduled from 18/05/2015 to 18/10/2015.

Data source: Electronic medical records.

Data analysis: Descriptive and growth dynamics (Δ).

Evaluation type: Internal, between-peers and retrospective.

Quality criteria:

1 – Diagnosis of iron deficiency anemia in pregnant women (microcytosis; hypochromia; hemoglobin: 1st and 3rd trimesters < 11g/dl; 2nd trimester < 10,5 g/dl; serum ferritin < 70 ng/ml).

2 – Iron supplementation of pregnant women with diagnosis of iron deficiency anemia (starting treatment after determination of serum ferritin).

Exclusion Criteria:

3 – Pregnant women not followed by their family doctor (by choice or pregnancy with mild to high risk).

4 – Women “misdiagnosed” as pregnant (still encoded in electronic medical records as pregnant, but already delivered).

Intervention: oral presentation at service meeting on the principles of iron deficiency anemia in pregnant women and first assessment data.

RESULTS: Sample: 62 pregnant women (on 1st assessment). After application of the exclusion criteria: 23 pregnant women - 9 were diagnosed with iron deficiency anemia and treated with iron supplementation. 2 of them were correctly diagnosed with anemia, and medicated, but serum ferritin was not requested. The remaining 7 were misdiagnosed with anemia, serum ferritin was not requested, but were medicated with iron supplementation.

CONCLUSIONS: At this point, it is apparent that the diagnosis and management of iron deficiency anemia in pregnant women is frequently inaccurate. It's important to warn family physicians to this issue, given that iron supplementation is often poorly tolerated, affecting the well-being of pregnant women.

Disclosure: No conflict of interest declared.

Keywords: iron deficiency, anemia, pregnant women

Opioid therapy in our population

Joaquín Brea Aymerich¹, Laura Torrente Nieto², Albert Mora Martinez¹, Mireia Cramp Vinaixa³, Teresa Basora Gallisa¹

¹Centro de Atencion Primaria, Reus 4-Horts de Miro. Institut Catala de la Salut.

²Centro de Atencion Primaria, Reus 1. Institut Catala de la Salut.

³Centro de Atencion Primaria, La Granja-Torreforta. Institut Catala de la Salut.

Background and AIM: Pain, the most common reason for consultation in primary care, is described as an unpleasant sensory and emotional experience associated with real or potential tissue injury. For its treatment we use the WHO's analgesic ladder: first step (NSAIDs and/or analgesics), second step (lower opioids+/first step) and third step (higher opioids+/first step). There is also the possibility of adding adjuvants (corticosteroids, anxiolytics, antidepressants, anticonvulsants, neuroleptics) and nonpharmacological treatments.

The aim is to know the characteristics of the pain in the patients treated with opioids in our area, evaluate if the treatment pattern is correct (according to the WHO's ladder), and assess the therapeutic compliance and the adjuvant treatment needs.

METHODS: Longitudinal retrospective study in an area with approximately 23000 inhabitants. Variables: total number of patients with opioids treatment. Of them: age, sex and reason of the treatment. Regarding the treatment: WHO analgesic ladder, type of opioid, adjuvant treatment and therapeutic compliance.

RESULTS: Of all the 231 patients with opioid treatment, 78% were women and 22% men, with a median age of 67. Pain type: 8,6% acute, 59,3% chronic and 22,1% sharp chronic pain. Reason of opioids treatment: 78% traumatological, 5% oncological and 1% surgical. WHO analgesic ladder: 75% of the total with second step (74,9% tramadol, 3,5% codeine) and 25% with the third step (11% fentanyl, 6% oxycodone, 5% buprenorphine, 2% tapentadol, 1% morphine, 0,4% hydromorphone). The 41,6% needed to combine two different drugs and 34,6% more than two. Coadjuvant treatment: 35,9% without and 64,1% with (13% anxiolytics, 13% antidepressants, 11% anticonvulsants, 3% neuroleptics, 2% corticoids, 20% with two or more drugs). The 90% had a good treatment compliance.

CONCLUSION: Most of the patients treated with opioids in our area are women. The main reason for using these drugs is for chronic pain with a traumatological origin. Minor opioids (2nd scale) are usually enough to control the pain, even though a large percentage need coadjuvant treatment to control it. The majority seem to have a good therapeutic compliance so we can consider them to be prescribed well.

Training as a quality criteria: descriptive study in Barcelona

Mireia Leal Negre, Carles Alvarado Montesdeoca, Cecília Doménech Rodríguez, Arantxa Castillejos Ruiz Molí Nou, Institut Català de la Salut, Sant Boi de Llobregat, Barcelona, Spain

Educating healthcare professionals is a key issue in the provision of quality healthcare services, and so, training in care quality is spreading. Quality is an innovative management philosophy that has been imported to healthcare from other industries and training is a cornerstone to archiving quality healthcare.

Meditating on the current situation in our organization, led us to want to know which was the starting point in order to settle down which areas we need to improve. So, we did a descriptive study, with the aim of collecting and analysing training needs. This study was conducted among professionals of different categories (health and non-health) in a health centre that serves to two populations, with a total of 21,000 inhabitants in Barcelona (Spain).

Data from our study was collected through personal interviews. The variables analysed were: professional category, sex, age, type of training requested, and if it matched with those detected by the management team, or not detected by management team.

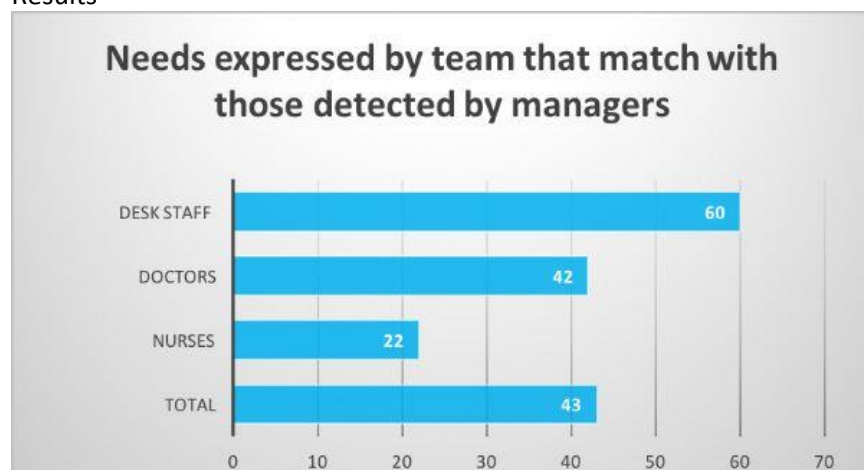

Participation was voluntary and the interview was strictly private.

The results show that only in a 43% of cases expressed needs match with those detected by the management team. By categories Doctors mach in a 42%, nurses only in a 22% and desk staff matches in a 60% of the cases. Only a 6% demanded Healthcare Quality training, however a 84% of the medical staff asked for training about cares.

In too many cases expressed needs differ from those detected by the management team and professionals do not want to be formed in Healthcare Quality training what is very worrying as it is where the strategic lines of the company are directed. We have to work harder in order to show our colleges how important quality training is for those who work in a health centre.

Brief advice on stopping tobacco use- quality of medical records

Ana Paula Fonseca, Isa Cruz, Márcia Soares

USF Cruz de Celas, Coimbra, Portugal

Background and Aim

Scientific evidence indicates that advice from a doctor significantly increases smoking abstinence rates. Our propose is to assess, on appointments were the problem "tobacco abuse" were identified, if the tobacco use were quantified and if any type of advice was given.

Method

Population: smokers with an appointment at our primary care unit from 01/02/2013 to 31/03/2013 (1st assessment period) and from 16/04/2014 to 08/06/2013 (2nd assessment period). Data source: Electronic medical records. Data analysis: Growth dynamics (Δ).

Evaluation type: Internal, between-peers and retrospective. Quality criteria: all smokers identified should have a quantification of the tobacco use and a medical counselling. Exclusion criteria: smokers attending intensive interventions.

Intervention: oral presentation at service meeting on the importance of brief intervention on tobacco cessation and the results of the first assessment.

Results

At the first assessment, 11 appointments were evaluated: none of them had a quantification of the tobacco consume and only 6 (45%) had a medical counselling recorded. At the second assessment, 54 appointments were evaluated: 46 (85%) had a quantification and 33 (61%) had a medical counselling.

Conclusions

Our results suggest that we improved the number of brief interventions, and probably the abstinence ratio.

Routine urinalysis in asymptomatic adults – a study for the continuous quality improvement of clinical practice

André Pereira Lourenço¹, Aníbal Martins², Catarina Miranda³, Catarina Peixoto³, Luís Alves Sousa⁴, Margarida Moreira⁵, Mariana Afonso⁶, Rute Mota²

¹USF Modivas, AcES Grande Porto IV, Vila do Conde, Portugal

²USF Santa Clara, AcES Grande Porto IV, Vila do Conde, Portugal

³USF do Mar, AcES Grande Porto IV, Póvoa de Varzim, Portugal

⁴USP Espinho/Gaia, Porto, Portugal

⁵USF das Ondas, AcES Grande Porto IV, Póvoa de Varzim, Portugal

⁶USF Corino de Andrade, AcES Grande Porto IV, Póvoa de Varzim, Portugal

Background & Aim

Urinalysis is commonly requested as a screening tool in asymptomatic adults, since it (is) can be an easy, informative and non-expensive test. However, there appears to be no benefit in such procedure, since it almost never changes the course of investigation and its frequent false positive results imply more invasive and costly techniques, yielding very few, if any, advantages for the patient. As such, our group intended to evaluate the frequency with which such test is requested in asymptomatic adults and, after an intervention designed to inform and clarify its indications, reevaluate – do old habits die hard, or is adequate information a true power favoring change?

Method

We performed a retrospective analysis of all “general health” consults performed by 58 doctors (31 specialists and 27 trainees) along 8 weeks, prior and after the intervention. Hypertensive and diabetic patients were excluded. We scrutinized each individual consult, evaluating if urinalysis was requested and, if so, if the patient reported any signs and symptoms that justified it. We then proceeded to an informative intervention intending to expose the frailties of using urinalysis as a screening test, and reevaluated some weeks after.

Results

4341 consults were reviewed prior to the intervention, and of 864 urinalysis requests, 760 (87,96%) were on asymptomatic individuals. After the intervention, a total of 4043 records were analyzed, with 72,04% of the urinalysis requests being incorrect (15,92% difference; 95%CI of the difference 10,82-21,03, p<0,001)

Conclusions

After the intervention, the percentage of incorrect urinalysis requested dropped significantly, showing the success of our intervention. These results reflect the high potential of change that even simple measures (like an informative session) can have. Thus, it is important to reinforce these measures, so that the good results obtained in this project can be maintained or even improved.

Promoting quality and integration of care through alliance contracting between funders, clinicians and the community. Using the New Zealand experience as an example

Les Toop¹, Vince Barry²

¹Department of General Practice, Univesity of Otago, Christchurch, New Zealand

²Pegasus Health Charitable Ltd, Christchurch, New Zealand

Traditional quality frameworks often contain multiple narrow clinical or process outputs rather than meaningful high level outcomes, too often focussed on individual bodily systems and diseases rather than on people and families, They are often applied to the work of single parts of the system e.g. general (family) practice.

In New Zealand, an innovative incentive quality framework has been developed, based around the triple aim, one which encourages integration across both health and social systems and whose top level system measures require input from multiple groups. Second level contributory measures use a quality improvement paradigm to manage variation rather than applying QA arbitrary thresholds. The implementation of this system requires the formation of district alliances between a variety of clinicians, funders and with community engagement. The guiding alliancing prinicple is to achieve consensus on approaches that foster integration and are best for patient / families and are best for system. This workshop will discuss the appicability of these principles to other countries and health systems.

Keywords: quality, integration, alliancing

Nursing Students' Use of and Information about Complementary and Alternative Medicine

Edibe Pirincci¹, Ferit Kaya², Sultan Erol¹, Fulya Onal³

¹Firat University

²Public Health Directorate

³Ege University

BACKGROUND & AIM: This study examines nursing students' knowledge, attitudes and behaviors regarding complementary and alternative medicine (CAM). **METHOD:** This is a descriptive and cross-sectional study. The study sample consists of all the students (550 persons) in the Health College Department of Nursing. The questionnaire form was given to all the students who came to school while the study was conducted. The study was conducted in collaboration with 489 students agreeing to participate on a voluntary basis. Students' rate of participation is 88.9%. The author obtained the Ethics Committee's approval and written consent from the institution. The data collected were analyzed using the SPSS Program. In the analyses, values of $p < 0.05$ were accepted as statistically significant.

RESULTS: Of the participating students, 56.2% are female, and their average age is 21.29 ± 2.02 . The CAM methods that students are most informed about are religious practices (14.2%), exercises (14.2%), vitamins (13.1%) and massage (10.6%). The frequency of using alternative medicine is 51.3%. The CAM methods most commonly used by students include herbal products, vitamins and exercise and religious practices. Males have a higher rate of using CAM methods ($p < 0.05$). Students' use of CAM methods increases significantly with age ($p < 0.05$). Of the reasons for using CAM methods, 71.8% were health problems, 50.1% were stress, and 44.4% were hair and facial care. Their main source of information about CAM methods is the internet, followed by family and then friends. Of the students, 13.3% had received training about CAM methods. Of those with such training, 64.6% used CAM methods, while 49.3% of the others used these methods ($p < 0.05$). The rate of recommending CAM methods to other people is 52.6%.

CONCLUSION: Nursing students have deficiencies of knowledge about this subject; however, more than half of the students still use CAM methods and recommend them to others.

P-1234

Quality of medical prescription of FOBT and colonoscopy as screening exam

Patrícia Rodrigues Cunha, Pedro Oliveira, Rosa Neves, Diana Brigas

Family Health Unit of Fiães, Santa Maria da Feira, Portugal

Introduction and objectives

Colorectal Cancer (CRCA) is one of the main oncological causes of morbidity and mortality in Portugal.

The existence of curative treatment and very high survival (>90%), when detected at an early stage, took the Portuguese General Directorate of Health (GDH) to create a standard on opportunistic screening of CRCA.

It's intended to assess and improve the quality regarding to the FOBT and colonoscopy prescription for CRCA screening.

Methods

The study comprised three methodological phases: initial assessment, intervention and reassessment. Dimension studied: technical and scientific quality; Unit of study: all individuals between 50 and 74 years old; Location: Family Health Unit (FHU) of Fiães; Exclusion criteria: all individuals with a personal or first-degree relative history of adenoma or CRCA, with diagnosis of inflammatory bowel disease and all patients who refused to undergo the exam; Sample Type: simple random sample of 206 patients; Evaluated criteria/indicators: FOBT prescription in the past year or normal colonoscopy during the previous 5 years; Type of evaluation: retrospective, internal and peers; Intervention: Educational and Informational.

Results

From the sample analyzed, 52% were women. The proportion of patients with FOBT and colonoscopy prescribed in the recommended timings was 55,3%. The most prescribed examination was FOBT (n=85), with 63% of prescriptions, representing the colonoscopy the remaining 37%. It can be concluded that there were shortcomings in compliance with the standard, being improved the quality standard, proven in the revaluation, after the educational intervention and informative.

Conclusion

The existence of 14 non-regular patients and an indicator which assesses the FOBT prescription every two years, rather than annually as recommended by the GDH, can justify the results obtained initially. The proposed intervention was adequate because after reevaluation there was an improvement in the quality standard of prescription of these examinations.

P-1235

Use of hypertension diagnosis and treatment guidelines by family physicians working in primary care and obstacles of guideline use

Nur Gundogan Gunes, Vildan Mevsim

Department of Family Medicine, Dokuz Eylul University Faculty of Medicine, İzmir, Turkey

Background

We aimed to investigate use of hypertension diagnosis and treatment guidelines (HDTG) in primary care by family physicians who work in primary care and obstacles of guideline usage.

Method

The study is a cross-sectional analytical study performed with 382 physicians who work in family health centers that were selected by cluster sampling method in the province of Izmir metropolitan. Two scales were developed with Delphi technique in the first step of our research in order to identify the use of hypertension guidelines and obstacles to the use guidelines. In the second step the scale was performed to physicians.

Results

61.5% of the physicians were male and 38.5% were female. Physicians under the age of 40 ratio (14.7%) were lower ($p > 0.05$). Physicians with graduation year 20-year and higher were more common with ratio of 52.9% ($p > 0.05$). Physicians who worked in primary care shorter than 5 years were 6.5% in ratio, percentage of family physician specialists was 16% ($p > 0.05$). Assessment of physicians' scale of HDTG considered in three categories and found that 18.6% used at a good level, 78.0% used in moderate level and 3.4% didn't use. The mean score of HDTG of female physicians (15.16 ± 3.26) were higher compared with men (14.20 ± 3.14), ($p = 0.005$). When we assessed obstacles of using guidelines, highest mean score was 3.73 ± 0.85 which interfere with the working conditions.

Conclusions

Family physicians use hypertension diagnosis and treatment guidelines at the intermediate level in managing hypertension patients. Physicians remarked that working conditions are the most important obstacles of guideline usage. Necessary arrangements should be made for increasing physicians' compliance to hypertension diagnosis and treatment guidelines.

³Melda KARAVUŞ, Marmara University, The Department of Public Health, İstanbul, Turkey

⁴Pınar AY, Marmara University, The Department of Public Health, İstanbul, Turkey

⁵Nimet Emel LÜLECİ, Marmara University, The Department of Public Health, İstanbul, Turkey

This descriptive research was carried out for the purpose of analyzing the social support and quality of life perceived by the mothers of children with cancer receiving chemotherapy. The sampling group of the research comprised the mothers of the children with cancer receiving treatment in the hematology-oncology service and polyclinic of Marmara University, Pendik Training and Research Hospital and in the outpatient chemotherapy centers. In order to measure the quality of life, The Quality of Life Scale (QOLS) of the family members taking care of a cancer patient was used, and to measure social support, The Multidimensional Scale of Perceived Social Support (MSPSS) was used. 99.18% of the mothers interviewed are married, whereas 31,8% of them are between the age range of 39-45 and 37.05% of them are primary school graduates. While the marital status of the mothers of children with cancer, their social security did not affect the quality of life, the scores of social support scale of the mothers who had no blood relation with their spouse, who were supposed to look after another patient, who were aged and had no younger kids were found to be significantly high. (p<0,05). Mothers who have children suffering from cancer spare all their time for their sick children and cannot get enough support in the course of the disease, which affect their quality of life in a negative way. In order to solve such problems, necessary educational and expert support should be provided for children with cancer and their mothers while also improving their living conditions.

Comparison with European Primary Health Care Quality Assessment EPA's and Ministry of Health ASM Evaluation Form

Melahat Akdeniz¹, Ethem Kavukcu²

¹Department of Family Medicine, Akdeniz University, Antalya, Turkey

²Department of Sports Medicine, Akdeniz University, Antalya, Turkey

Background. Quality of the primary care practices is also important for both physicians and staff in primary care as well as patient satisfaction with the service they receive. The EPA tool was first tested in more than 270 practices in Europe. The aim of EPA is to have an impact on the quality improvement on the premises of the practice and in practice organisation. In Turkey, Primary health care services has been given in the Family Health Centers since 2010. ASMs are supervised by the Ministry of Health and a standard form that is used in the control. ASM evaluation forms compared with the EPA in this study.

MATERIALS-METHODS: Firstly permission of translation was received first translation because lack of translation Turkish of EPA; then was translated into Turkish by all the researchers separately. It was then agreed a joint text combining translation. Secondly, it were compares Ministry of Health's ASM evaluation forms with the EPA in terms of common areas and differences.

RESULTS: Physical and technical requirements are located in both forms. The evaluation forms of ASM describe the internal and external features of ASM, ASM building, medical equipment, essential medicines in detail. In the EPA, accessibility is further highlighted; building inside nesting features are less detailed. Availability of medical equipment, and essential drugs were highlighted, but not provided lists. ASM assessment form is questionable whether they are physicians and their staff to the task. The patients, physicians and staff's thoughts and feelings about institution and working conditions have a higher priority area In the EPA,

Conclusion. The goal of the EPA is to assure the standard and qualified health services in primary care alongside buildings and properties. To use the EPA can provide significant improvements; increase the quality of health care in our country.

Impact of electronic prescriptions in the demand for care

Hector Leonardo Lugo Ramos, Rocio Lobato Martinez, Jose Maria Fernandez Gonzalez, Juan Jesus Rodriguez Vallejo

Hospital Jerez de la Frontera - Cadiz

OBJECTIVES:

To know how to influence the final implementation of the electronic prescription in Primary Care in demand for consulting assistance

MATERIAL-METHODS:

A descriptive cross-sectional observational study. Data collected from a sanitary zone digital system including the total number of patients treated at a health center differentiating by gender for the first six months of final implementation of electronic prescriptions compared with the same data are analyzed in the year above.

RESULTS:

Preliminary studies showed a decrease in the number of health demand something more than 14% difference remaining stable attendance rate of women (55 %) compared to male (45%).

CONCLUSIONS:

A digital system that allows almost unlimited prescription drugs to patients reduce demand clinic substantially a few months of use. However, there is clear frequency by the female gender. This situation allows the patient to go not only for their monthly prescription and gives opportunity to demand assistance to patients without chronic diseases.

The Need of Developing TB-DM National Program for Diabetes and Tuberculosis Comorbidity: {Lesson Learnt from Experience of Faculty of Medicine Universitas Indonesia in West Java Province, Indonesia}

Della Puspita Sari¹, Irene Darmawan¹, Lorens Prasiddha¹, Trevino Aristakus Pakasi², Indah Suci Widyahening²

¹Faculty of Medicine Universitas Indonesia, Jakarta, Indonesia

²Department of Community Medicine, Faculty of Medicine Universitas Indonesia, Jakarta, Indonesia

Background

Developing countries are currently facing double burden of disease, the comorbidity of tuberculosis (TB) and diabetes mellitus (DM). The WHO and International Union against Tuberculosis and Lung Disease (IUATLD) managed to elaborate a collaborative framework with the World Diabetes Foundation to solve the issue. The meeting recommended an early detection and management of DM-TB. Since 2013, a guideline for primary health care (PHC) was prepared by the Faculty of Medicine Universitas Indonesia and implemented in Jakarta, Bogor, Ternate, Kupang and Manado, where the burden of diabetes were quite high. After a year of implementation, we did supervision in Bogor, West Java. The study aimed to describe lesson learnt of the guideline implementation in Bogor.

Method.

A system approach was applied in the supervision. We performed an in-depth interview to the program manager and other health personnel in the PHCs to describe how they diagnose and treat DM-TB, number of patients, and asking the usefulness of the guideline.

Results

From three samples of PHCs in Bogor, case finding of TB-DM was 14 out of 111 registered TB patients. Two issues hindered the application of the TB-DM guideline. The first was limited resources and facilities. The second was the absence of target coverage as the PHC expected. In the patient care aspects, the guideline to screen DM among TB patients was well adapted and useful but not for TB screening among DM patients. It was rather difficult because limited resources and facilities. In the interview, health personnel suggested to make as a national program, with certain targets. Otherwise, there was no enforcement to implement the guideline.

Conclusion

The guideline was quite useful for the PHC, but need more enforcement in the implementation, i.e. becoming a national program. This was also recommended by the WHO-IUATLD-WDF meeting, in order to optimize the program achievements.

Analysis of satisfaction in maintaining of the implantable venous acces system in the primary healthcare centre of manlleu

Alicia María Díaz, Gloria Padullers, Sara Belmont, Silvia Altimiras, Meritxell Cassasas

The Primary Healthcare Centre, Catalan Institute of Health, Manlleu, Vic, Barcelona

BAKGROUND

The Primary Healthcare Centre (PHC) of Manlleu, since November 2011, is doing the control and maintenance of the Implantable Venous Access System (known as Port-A-Cath® reservoir), to patients who have stopped making active treatment with chemotherapy.

Our concern is how patients live this new way to perform the procedure that was previously done in the hospital.

AIM

- Evaluate patient satisfaction with the procedure carried out by the PHC.
- Analyze the possible improvements in the development of the procedure.

METHOD

Telephone survey to all patients with the system (Port-A-Cath reservoir), about satisfaction on the procedure conducted in PHC.

RESULTS

- 5 of the 23 interviewed did not answer. 74% were women and 26% men.
- The most common malignancy is breast cancer (43%), followed by colon cancer (21%).
- The average age is 55 years.
- Be pensioner was the most frequent employment situation (61%).
- The average time of attention in the PHC has been 19 months.
- None of the patients presented any problems caused by the reservoir which needed its referral to the hospital.
- In terms of accessibility (flexitime) and the improvement in the economic expense 94% of respondents listed as excellent. 100% as excellent in facility in traveling and the reconciliation of work and family schedules.

CONCLUSIONS

From the 18 patients who responded the survey, 100% are satisfied that the procedure is carried out in their PHC. The monitoring of Port-A-Cath in PHC has proven to be effective and safe.

Study about the use of benzodiazepines

Ángel Hurtado De Mendoza Medina¹, Carmen María Jiménez Herrera², Ruth Muñoz Maya³, Elvira García Martín⁴

¹CS Don Paulino García Donas, Alcalá de Guadaíra. AGS Sevilla-Sur, Andalussia, Spain

²CS Nuestra Señora de la Oliva, Alcalá de Guadaíra. AGS Sevilla-Sur, Andalussia, Spain

³CS Don Paulino García Donas, Alcalá de Guadaíra. AGS Sevilla-Sur, Andalussia, Spain.

⁴CS Virgen de Consolación, UGC Utrera Sur, Utrera. AGS Sevilla-Sur, Andalussia, Spain

Background and Aim: Analysis of the clinical profile of patients taking benzodiazepines in a Family Medicine Clinic in southern Europe and whether such benzodiazepine (BZD) prescription is suitable according to the diagnosis and type of benzodiazepine in terms of half-life.

Method: Study on the prevalence of benzodiazepine prescription. Retrospective, descriptive. Adults (>18) with BZD prescription at the time of the study (January 2015) in a family medicine consultation (1345 people). We scanned the prescriptions made at the time of the study, patient data (age, gender, prescription data, duration, diagnosis, type of benzodiazepine).

Results: Of these 1345 patients, 219 (16.28%) had been prescribed benzodiazepines as recorded in their digital history at the time of the study.

BZD consumer profile was: female (68.2%), of which 28.7% were in an age range between 53 and 69 years-old. In most cases (40.05%) there was not an established diagnosis. The main diagnoses found were: anxiety-depressive disorder (39.2%) and musculoskeletal disorders (12.3%).

In the group of women the main diagnosis was anxiety-depressive disorder while in men musculoskeletal pathology was more prevalent.

A diagnosis analysis by age showed that population under 40 years-old presented mainly mechanical pathology while insomnia was common in people over 65 years-old

Types of prescribed benzodiazepines: Short half-life (6.7%), Intermediate Half-life (58.2%), Long Half-life (35.1%)

Conclusions: Women are the population were benzodiazepines are most prescribed, in a context of anxiety-depressive syndrome as main diagnosis.

There are a lot of fragile patients being treated with benzodiazepines. In these patients, we should watch over BZD because they would be contraindicated.

There is a great scope for improvement in the use of this drugs, since a large percentage of patients use them without a definite diagnosis.

Evaluation of electronic prescribing after one year use

Arzu Uzuner¹, Pemra Ünalın¹, Ezgi Yiğit², Nurullah Yazlı², Şeyda Aslan², Halis Uğur², Tuğba Çetin², Gülşah Yiğit¹

¹Department of Family Medicine, Marmara University medical School, İstanbul, Turkey

²Marmara University medical School, İstanbul, Turkey

INTRODUCTION: Electronic prescribing is a recent application in Turkish health system to prescribe the medications. With this applicaiton mostly encountered writing errors, fake prescriptions and wrong medication use are expected to be avoided, reimbursements to be timely and easier.

AIM: The aim of this study was to investigate the e-prescription by a broad perspective.

METHOD: This is a qualitative study. Physicians and pharmacists were interviewed by semi structured in dept interviews; patients by focus groups. On purpose sampling which enabled detailed investigation based on the different age, education level, working conditions for the patients; sex, age, specialty, working place for the doctors and the location of the pharmacy and the experience for the pharmacists. All the interviews were thematically analysed depending on the transcript of the audio tape records.

RESULTS: There is a general satisfaction within the groups. Still some of the patients are not aware of the system. There are some faults by entering the passwords into the system or some technical difficulties in the systme. Print out is not usually given to the patient. The advantages are easy access to the medications, leass bureaucratic procedure, economization of paper consumption. The effects of generic medication use on the e-prescription.

CONCLUSION: Technical interventions can solve the dissatisfying system based disadvantages. A shared electronic system can be created so that the prescription entries could be seen by the hospitals all over the country.

Clinical practice guidelines (CPGs) are one of many tools that can be used to improve the quality of care provided by health professionals, especially when they are designed to support appropriate or necessary behavior change. Recently, clinical practice guidelines have become increasingly popular all over the world. The number of the national and international organizations that have been laboring about guidelines has been rising.

The aim of this study is to determine how to assess the quality of clinical practice guideline and approach the examples of the different countries.

Clinical practice guidelines are developed by different governmental and non-governmental institutions and international guideline networks all over the world. Due to wide variations in quality of clinical practice guidelines, many tools were developed to separate the high and low quality guidelines from each others. Recent studies emphasize that the most appropriate choice is to use AGREE II or DELBI instrument to make an comprehensive guideline evaluation. In Turkey there are few studies about the assessment of the clinical practice guidelines, developed by ministry of Health and non governmental institutions. With this study these experiences will be shared with the family physicians and also its strenghts and weaknesses will be discussed.

Jack3D: May Be A Cause of Persistent Atrial Fibrillation?

Özden Gökdemir¹, Hüseyin Dursun², İnce Tuğçe Çöllüoğlu², Ayşegül Karaman³, Dayimi Kaya²

¹DOKUZ EYLÜL ÜNİVERSİTESİ TIP FAKÜLTESİ AİLE HEKİMLİĞİ ANA BİLİM DALI-İZMİR

²DOKUZ EYLÜL ÜNİVERSİTESİ TIP FAKÜLTESİ KARDİYOLOJİ ANA BİLİM DALI-İZMİR

³DOKUZ EYLÜL ÜNİVERSİTESİ TIP FAKÜLTESİ İÇ HASTALIKLARI ANA BİLİM DALI-İZMİR

Multicomponent dietary bodybuilding supplements comprise as herbal preparations to the public. It's herbal origin is emphasized while told that has no adverse effect as promotion. One of these product is Jack3D which consists of arginine alpha-ketoglutarate, creatine monohydrate, beta alanine, caffeine, 13-Dimethylamylamine HCl, Schizandrol A, Citric Acid, Silicon Dioxide, Acesulfame Potassium, etc.

Atrial fibrillation (AF) in young patients without structural heart disease is rare. Therefore, when the arrhythmia is present in this population, reversible causes must be identified and resolved. Hypertension, Coronary Artery Disease, Heart Valve Diseases, chronic lung disease, heart failure, cardiomyopathy, congenital heart disease, pulmonary emboly are the most common reasons of the atrial fibrillation and less common causes are thyroid disorders, pericarditis. Less common reasons of AF, are of illicit drug-stimulant use, acute alcohol intoxication, overuse of caffeine, electrolyte imbalance, metabolic disorders, infections or genetic factors.

This case is also remarkable because it's the first case in literature which reports a young man who developed persistent AF depends on the use of Jack3D.

A 22 year-old man came to the emergency department complaining of palpitations and dyspnea of abrupt and recent onset (>2 hours). There was nothing significant in his medical history. His blood pressure was 130/80 mmHg, pulse was 126/min and arrhythmic, respiratory rate was 18/min. Tachyarrhythmia was detected in his physical examination. 130 beats/min AF speed was observed in electrocardiography. No structural cardiac pathology was detected by the transthoracic echocardiography. Amiodorone infusion was applied and continued for 24 hours period. He converted to normal sinus rhythm. On direct questioning about herbal products and dietary supplements, he revealed that he took Jak3D which was a bodybuilding supplement.

Multicomponent dietary bodybuilding supplements are mostly used to increase muscle mass. Many researchers reported that to use compound of creatinine and arginine-alpha-ketoglutarate is effective to increase the muscle endurance, repeated Wingate tests are also evidence of the improvement in muscle power. However, fatal side effects in young adults, in particular cardiovascular side effects should not be underestimated.

Acne: Does youth assess as an illness?

Ilyas Erken¹, Ülkü Yıldız³, Melike Çağaydın¹, Gizem Limnili², Nilgün Özçakar¹

¹Department of Family Medicine, Dokuz Eylul University, Izmir, Turkey

²Medical Center, Dokuz Eylul University, Izmir, Turkey

³Çukurca Hospital, Hakkari, Turkey

Background and AIM: Acne vulgaris, a chronic disorder of the pilosebaceous units, is common in adolescents. Acne is also the most common skin disease in adults. The early detection and appropriate treatment of acne is essential in the prevention of severe acne and scarring, and the consequent adverse psychosocial disabilities resulting from feelings of embarrassment, frustration and poor self-esteem. Emotional issues in young individuals with acne must be identified appropriately.

METHOD: This was a cross-sectional survey involving students who applied to Dokuz Eylul University Medical Center with any reason of health. They were administered a questionnaire gathering their socio-demographical data, presence of acne, prior or current treatment, general knowledge about causes of acne, questions regarding the quality of life and Rosenberg Self-Esteem Scale's first ten questions. SPSS 15.0 program was used for statistical analysis and p<0.05 was accepted as statistical significant.

RESULTS: Two hundred and forty seven students were included and 63.7% were women. Mean age was

21.40±2.38. Majority of the students (99.3%) had acne but 41.3% of acne problems had lasted before three months. Acne was defined as an illness by 53.4% of the students and 38.1% visited a doctor for acne treatment. Relationship between suffering from acne for longer than three months and Rosenberg Self-Esteem Scale scores were not statistically significant ($p>0.05$).

CONCLUSION: Despite the high prevalence of acne, there is still much deficiency of knowledge and wrong beliefs about acne. This indicates that there is an urgent need for education about etiopathogenesis, potential complications and importance of effective treatment for acne.

Emergency department, Al Bashir Hospital, Amman, Jordan

Background and AIM: Increasing demands on health services have resulted in a number of innovations in delivering care. In November 2005, a unique new care model was started in the Emergency Department of Al-Bashir Hospital, the largest government hospital in Amman, Jordan. Family medicine physicians (specialists and residents) started working and are still working in newly added clinics to the Emergency Department, providing 24-hour primary care services to non-urgent patients; 'inappropriate attenders', on a non-appointment basis, with the aim of decreasing the pressure on the overburdened Emergency Department. Aim of the study was to identify characteristics of patients attending Family Medicine Walk-in-Clinics.

METHODS: Reviewing the emergency department registration books from April 18 till May 17 2010. A total of 10000 patients were identified, according to age, sex, main complaint and time of attendance.

RESULTS: Total number of patients 10000. Males - 5333 (53.33%), females - 4667(46.67%). Male to female ratio was 1.14:1. 1 to 5 years - 2852 (28.52%). 1 to 30 years - 7329 (73.29%). Main presenting complaint was respiratory tract problems in 4090(40.9%) patients, of which upper respiratory tract infection constitute 2776 (27.76%), followed by gastrointestinal tract problems in 2937 (29.37%), of which acute simple gastro- enteritis constitute 1782 (17.82%), renal problems - 549 (5.49%), back ache - 401(4.01%), cardiac problems-381 (3.81%) and skin problems - 361 (3.61%). 434 (4.34%) requested sick leave. Shift B (17:00 - 23:00) was the busiest - 4301 (43.01%) patients. 831 (8.31%) patients were referred to on call teams.

CONCLUSION: Children and young adults with upper respiratory tract infections were the main attendees. Main patient attendance and workload was in shift B. Providing primary care services in the emergency department offer safe effective and popular services.

“Correlation authorized by sanitary inspection with increased spending on primary care”

Alfonso Piñana Lopez, Rafael Luquin Martinez, Concepción Alonso Garcia, Jose Miguel Bueno Ortiz, Jesus Fernandez Lorencio, Jose Eduardo Caballero Martinez, Susana Martinez Gonzalez, Maria Lucia Garcia Guerrero, Beatriz Guerrero Diaz, Jose Lopez Gonzalez

Health Center Virgen de la Caridad, Area 2Cartagena, Murcia Health Service, Spain

“Background & Aim

the adequacy of the budget in pharmacy diversion between health centers in the same area of health leads us to find a way to adapt the diversion of the budget in pharmacy with the characteristics of the general population

Method

We determine the percentage of budgetary slippage of each general practitioner health center more diversion health area of 2014 to map each family doctor visadas total number of prescriptions or authorized inspection

Results

The% of prescriptions authorized by the sanitary survey ranged from 0.8% to 17.6% and% deviation pharmaceutical expenditure by general practitioner health center ranged from 3.44% to 82.74% of the budget. Getting a correlation coefficient of 71.9%

Conclusions

The correlation indicates that the greater the number of authorized inspection recipes will find greater diversion of budget so we conclude that while health centers in the area are homogeneous in age groups, the health status of patients differ yes. It would also be desirable generalization of an index of approved recipes for inspection as a compensatory mechanism to own budgetary slippage”

Keywords: prescription drug spending

AIM: Adolescence is an important developmental process that relates to many physical, emotional and behavioural problems due to structural, physical and also neuro-chemical changes of brain. Understanding this developmental process and recognition of any delay is important for the life of adolescents. This case presentation discusses the importance of periodic physical examination of General Practitioner/Family Physician.

CASE: 21-year-old male patient was admitted to emergency department of Ege University Faculty of Medicine because of seizure. He was conscious with blood glucose 440 mg/dL, urine ketone 150 mg/dL, and the pH value 7.1. His initial diagnosis was diabetic ketoacidosis due to unrecognized diabetes mellitus. Dexamethasone was started for its anti-oedema effect after he attended to emergency service. He was hospitalized for further investigations.

His complaints were dry hands, weakness, fatigue, weight loss, catarrhal purulent otitis in the right ear for a week ago, and he had polyuria and polydipsia for last month. His medical detailed history about seizures included brain tumour (anaplastic ependymoma grade 3) with chemotherapy and radiotherapy. He used antiepileptic treatment when followed up regularly until a year ago and he wasn't using his drugs for last year.

His testis couldn't be palpated and couldn't be visualized by scrotal ultrasonography. His flaccid and stretched penis size was <4 cm. His FSH-LH and prolactin values were high and total testosterone, DHEA-S were low. Chromosome analysis result was XX. His primary diagnosis was Klinefelter's Syndrome.

DISCUSSION: His denial of antiepileptic treatment for last year caused seizure, however his main problem was the physical differences that he found out himself. Unfortunately, he didn't have a complete physical examination that would give him the chance of early diagnosis, before adolescence. Till his situation became a life-threatening problem, it wasn't visible. The periodic physical examination shouldn't be ignored not to have the diagnosis by coincidence.

Self-rated health among peoples: a cross-national comparison

Aliye Mandiracioğlu¹, N. Emel Lüleci²

¹Ege University Faculty of Medicine Department of Public Health

²Marmara University Faculty of Medicine Department of Public Health

Background & AIM: Self-rated health (SRH) is used extensively in cross-national studies to evaluate a population's state of health, because it is simple and global. The aim of the study is to explore cross-cultural differences in self-rated health. METHOD: Data used in this study are from the sixth wave (2011–13) of the World Values Survey from Turkey (n:1500), Azerbaijan (n:7109), Kazakhstan (n:1002), Kyrgyzstan (n:1502), Uzbekistan (n:1605). SRH is measured using a 5-point response scale. The respondent's characteristics are included. RESULTS: In the four countries, more than 80% of the respondents have secondary or higher education, Turkey the rate is about 63%. People in Kazakhstan are most likely to report low income level. The prevalence of poor self-rated health is highest among participants from Kazakhstan (6.3%). The percentage of self evaluation "good" is 75.2.0% for Turkish people, and 56.4 % Uzbek. The percentage of positive self-evaluation in the Azerbaijan is 68.7%. SRH is worse among females in all countries. Married persons have significantly better health than did unmarried persons. There is poorer health among elderly persons. In all countries, people with elementary school or less have poor health compared to those with higher education. Lower income is significantly related to poor health in all countries. Conclusions This study results indicate that age, gender, income, and degree of education are relevant SRH in all countries. There are differences in SRH between countries. There are a lot of explanations for the differences in SRH across countries. Some of the explanations may be differences in cultural factors (such as life style, social structures) and economic inequalities.

Knowledge, Attitudes and Behaviors of Cigarette and Hookah Smokers About Hookah Smoking

Selen Soyuluol Gulec, Dilek Toprak

Family Medicine Outpatient Clinic, Şişli Hamidiye Etfal Research and Training Hospital, Istanbul, Turkey

AIM: In this study, we aimed to compare the effects of smoking hookah and cigarette to the level of carbon monoxide in the breath and also to evaluate the knowledge, attitudes and behaviors of individuals who smoke.

MATERIALS-METHOD: This study conducted between 25.02.2014-15.08.2014 in İstanbul hookah cafes and Şişli Hamidiye Etfal Research and Training Hospital Family Medicine Outpatient Clinic, among the individuals over 18 years who only smoke cigarette, only hookah and smoke both of them. Beside the sociodemographic informations, questions about knowledge, attitudes and behaviors were asked to these three groups with face to face method.

RESULTS: Totally 208 participants were included the study. Most of them were male (88.5%; n=184); married (71.6%;n=149) free-employed (%29,3;n=61) and graduated from university (49,5%; n=103). The mean age of the group was 29.16±10.80. Water pipes were smoked mostly in hookah cafes (96.6%;n=201) and the most common reason of this was "being together with friends" (%54.3; n=113). The most effective factor to start smoking waterpipe (%39.9;n=83) was "to enjoy". Hookah was smoked mostly ≤5 times/month (%43.8;n=91) and the average duration to smoke waterpipe was 7,42±6.08months. Flavored hookahs (94.2%;n=196), especially Apple flavored hookah (55.8%;n=110) were usually preferred. While 85.1% of the participants (n=177) thought waterpipe is harmful, 61.1% (n=127) of them thought hookah smoking is not addictive as cigarette. Equal number of people thought as hookah/cigarette smoking is more harmful to health (42,3%;n:88)

Participants (70,2%;n:146) didn't found warning signs on hookahs useful. Most participants thought adding fruit particles and/or aroma into the waterpipe; passing through water does not remove the harmful substances in it.

CONCLUSION: This study showed that smoking hookah increases breath CO level more than cigarette. Researches about Hookah use would help for further Projects and emphasise the importance of this health problem.

"{".Generalised woolly hair: Case report "}"

Beril Gümüş Demirel¹, Rafet Koca¹, Nilgün Solak Tekin¹, Ayşe Semra Demir Akca²

¹Department of Dermatology and Venereology, Bülent Ecevit University Faculty of Medicine,Zonguldak, Turkey

²Department of Family Medicine,Bülent Ecevit University Faculty of Medicine, Zonguldak, Turkey

Woolly hair is a rare congenital abnormality of the scalp hair characterized by kinkiness of the hair which is resembling negroid hair. Prevalance is unknown and it can be present at birth or appear in the first months of life.

Hutchinson et al. Classified wooly hair into three variants: a localized variant, woolly hair nevus and generalized variants. Generalized variant can be autosomal dominant hereditary woolly hair and autosomal recessive familial wooly hair. In dermatologic examination there is a marked reduction in the diameter of hair shafts which is usually poorly pigmented. Growth rate and the ratio of anagen/telogen are normal. Generalized woolly hair affects the entire scalp and can occur in isolation or in association with other cutaneous and extracutaneous abnormalities. It can occur in combination with Menkes disease, Naxos disease, Karvajal syndrome, Cardiofaciocutaneous syndrome and Noonan syndrome. Keratosis pilaris has been a well known association of woolly hair, and can also be a part of the Naxos or Carvajal syndromes.

We report the clinical case of a 14 year-old girl with generalized woolly hair. Marked keratosis pilaris was seen on the external side of arms. Cardiac evaluation did not show any abnormalities. There was a similar hair abnormalities history in her cousin. In physical examination there are no alteration or characteristics associated with other syndromes were found.

²Servicio Valenciano de Salud

³Universidad de Murcia

OBJECTIVES

Understand the use of written words to determine greetings, courtesy acknowledgments in primary care online. and attitudes, beliefs and experiences of adolescents and their mothers about nutrition.

PATIENTS AND METHODS

Qualitative methodology interpretive method. Where all the queries from a primary care physician received online at the health center of Cartagena West Murciano Service are analyzed. The criteria of linguistic heterogeneity is the presence of a welcome (Hello, good morning, good afternoon,), presence of words agradecimiento (thanks) and finally terminating words written some words of courtesy (greetings, Sincerely, etc.) With completion of calculating the percentage of their respective use.

RESULTS

Of total Internet e analyzed (93 mails internet) it follows that any greeting presentation appears, in 35.5% appears a word of thanks and 36.6% in 54.4% displayed some word courtesy. With these percentages say that it is common to find at least one or two words of greeting, gratitude and courtesy in the physician-patient communication over the Internet implying a deal by the user towards your next family doctor and cordiality toward.

Conclusions

The courteous treatment we can say that Internet communication has to be enhanced and desarrollada to its conclusion

²Family Health Care Unit Alcaldes Faria, Barcelos, Portugal

³Family Health Care Unit São Lourenço, Braga, Portugal

⁴Family Health Care Unit Pro Saúde, Vila Verde

Background & Aim

Intradermotherapy known as mesotherapy, is a medical procedure introduced by Pistor in 1958 that consists in the application of intradermal injections of diluted pharmacological substances, at very low doses, between the epidermis and dermis as close as possible to the site to be treated, with a minimum undesirable effects and without involving other areas of the body. There are reports of the use of intradermotherapy to treat painful diseases (fibromyalgia, gout, headache, neuralgia, low back ache, sports injuries like sprains, strains, bursitis and tendinitis), skin diseases (alopecia) as well as unaesthetic conditions (colloid scars, wrinkles).

METHOD: Literature review of the clinical use of mesotherapy

RESULTS: Each session of mesotherapy involves superficial injections of medication using specialized short needles and specific techniques directly over the affected structures.

Medication mixtures used to inject in mesotherapy are commonly called "Mesotherapy Cocktails". The most common cocktails used in the therapies include local anesthetics, NSAIDs, decontracturants / muscle relaxants, corticoids, vasoactive drugs and phlebotonic drugs. The contraindications to mesotherapy include hypersensitivity to any component, body mass index greater than 30, pregnancy, lactation and less than 18 years of age. Side effects following mesotherapy are extremely rare in experienced hands and if they occur they are usually mild. Non-specific common adverse effects include nausea, vomiting, diarrhea, mild pain, skin hyperesthesia, edema, itching, erythema and tender subcutaneous nodules at injection site.

CONCLUSIONS: Despite the increasing number of studies, there are few indexed ones. Adequate methodological studies need to be conducted so that the true value of intradermotherapy with useful procedures can be applied in family medicine.

Longitudinal trends in the morbidity from musculoskeletal disorders and the consumption of the anti-inflammatory drugs in Croatia

Martina Menegony¹, Leonard Lamot², Gordana Prljević³

¹General Hospital Slavonski Brod, Croatia

²Health Center Krapinsko-zagorska County, Krapinske Toplice, Croatia

³Family Practice „Dr. Gordana Prljević“, Krapinske Toplice, Croatia

Background & aims

Musculoskeletal disorders (MSDs) are an increasing healthcare issue globally, being the high ranking cause of disability. Neck and low-back pain are the most common complaints seen in the primary health care (PHC), although the numbers of inflammatory conditions are increasing. There are several researches on MSDs in PHC, but limited in the scope and time. The aims of this study are to investigate trends in the morbidity of MSDs registered in Croatian PHC and the consumption of MSDs drugs.

Methods

From the Croatian Health Statistics Yearbook, 2005-2013, data related to the MSDs morbidity registered in PHC (ICD-X version) were obtained. Data on MSDs drugs (M01-M09) consumption expressed in DDD/TID and in Croatian currency, kunas, were taken from annual reports, 2005-2013, of Croatian Agency for Medicinal Products and Medical Devices in which the ATC classification index was used.

Results

The number of diagnoses of MSDs recorded in PHC during the observed period increased from 798 358 recorded in 2005 to 1 437 931 in 2011, when it was the highest. While the number of kyphosis, scoliosis and lordosis decreased, the number of inflammatory MSDs increased in 240% and intervertebral disc disorders and other dorsopathies in 200%. At the same time, the consumption of MSDs drugs increased from 37.29 DDD/TID in 2005 to 57.84 in 2013 or from 148.455.470 Croatian kunas in 2005 to 208.434.476 in 2013, occupying in between 4th and 6th place in overall drug consumption. The higher increase was observed among the non-steroid anti-inflammatory drugs (M01), especially ibuprofen and diclofenac (increase in 220% and 180%).

Conclusions

The obtained results indicate that the MSDs registered in Croatian PHC are continuously increasing, followed by the increased trends in MSDs drugs consumption, especially ibuprofen and diclofenac consumption.

P-1255**Marmara University School of Medicine Basibuyuk Campus's Workers' Sleep Quality Anxiety Level and Related Factors**

Ayşe Gülsen Teker, Nimet Emel Lülecı, Seyhan Hıdıroğlu, Zülal Tarımtay, Türkan Cengiz, Muzaffer Ece Hakan, Ayşe Eren Yılmaz, Tuğba Altunkaya, Elif Uğur, Melda Karavuş

Department of Public Health, Marmara University Medical Faculty, Istanbul, Turkey

BACKGROUND and AIM: Sleep disorder is a disease that directly affects the health status but rarely questioned. Sleep disorders affect about 20-30% of the general population, although it is common to all over the world.

Generalized anxiety disorder is the most common psychiatric disorder seen in patients with sleep disorders. The aim of this study is to investigate Marmara University Medical Faculty (MUMF) Basibuyuk Campus's workers' sleep quality and anxiety level, to find the correlation between them and to determine other related factors.

METHOD: The sample of study collected from 130 MUMF Basibuyuk Campus's workers who agreed to attend in. Demographic information form, Beck Anxiety Inventory Scoring (BAIS) and Pittsburg Sleep Quality Index (PSOI) were applied to participant. The data was processed by SPSS 22.

RESULTS: The participants were 130 people, %68.5 female, %31.5 male. Mean age was 36.6 ± 10 . Participants' PSOI's mean: 5.61 ± 3.3 , BAIS mean: 8.6 ± 9 . According to our data sleep quality positively affected by high income, going to bed at the same hour, having good relationship with the family and social environment. Sleep quality was not affected by sex, age, chronic illness. The significant correlation was found between sleep quality and anxiety level ($r=0,48$ $p=0,01$). Anxiety level is negatively affected by female sex, having chronic illness, chronic medication, known sleep problem, drinking coffee, tea, eating meal before going to bed and having bad relationship with social environment.

CONCLUSION: This study showed that sleep quality and anxiety level were significantly correlated. Both of them are affected by income level, chronic medication and social relationship. However to find the possible triggers of the vicious cycle between sleep quality and anxiety level, more studies are required to be designed.

P-1256**Lemon Juice and Parsley, Union is Strength**

Polat Nerkiz

Department of family medicine, Gümüşsuyu Asker Hastanesi, İstanbul, Turkey

Background & AIM: Nowadays plants and herbal medicines are used widely as well as other treatment options to be protected from the diseases and for treatment of diseases. In health programs on TV many herbal mixtures are recommended. Mixture of lemon juice and parsley is one of the recommends increasing in popularity with the claim that the effect of healing the fatty liver and weight-loss.

Method and RESULTS: 47-year-old female patient, who got consulting from a wellness expert to lose weight, did not lose weight at a level to meet the expectations at the end of 3 months period. She admitted to our center because she was told that an underlying metabolic disturbance could cause this. In routine biochemical tests we found Thyroid stimulating hormone (TSH): 1.72 IU/L, fasting blood glucose: 92 mg/dL, Aspartate aminotransferase (AST): 46 IU/L, Alanine aminotransferase (ALT): 78 IU/L. Patient had no liver dysfunction or no known history of the disease will lead to disorder. In a detailed history, we determined that she did not use any drug but she drunk at least 6-7 glasses of mixture of lemon juice and parsley per day in order to contribute to weight loss. Patient was told to stop drinking this mixture. In tests after 3 weeks, we found AST: 24 IU/L and ALT: 26 IU/L.

CONCLUSIONS: Herbal medicines are widely used nowadays. However, the vast majority of physicians do not question enough the use of these products and patients do not mention about them if they were questioned especially because they do not accept them as drugs. We must pay attention to this subject while taking history.

Can simple changes in family practice reduce polypharmacy in the elderly?

Laila Abdullah

Department of Primary care and Population Health, UCL

Background and Aim

Elderly people often take a variety of medications, yet some of these may no longer be needed or might interact with other drugs. Elderly people are at greater risk from adverse drug reactions and interactions which may lead to falls, drowsiness and cognitive impairment. Up to one in five hospital admissions in the elderly have been attributed to adverse drug reactions. We therefore need more stringent and focused medication reviews for frail elderly people. This study aimed to see whether simple changes in family practice could reduce polypharmacy in the elderly.

Method

The study is using a before and after design and is running from October 2014 to May 2015. One family practice in England searched its records to identify people aged over 75 on ten or more medications who had an unplanned admission in the past year. After certain exclusions, these patients were invited to a medication review and 20 out of 26 people attended (78%). Patients completed a baseline questionnaire about their medication and quality of life. Medications were reduced according to the no TEARS and STOPP protocols in a 20 minute review. 15 out of 20 people had one or more medications stopped (75%). Patient's 'named doctors' were informed of any changes.

Results

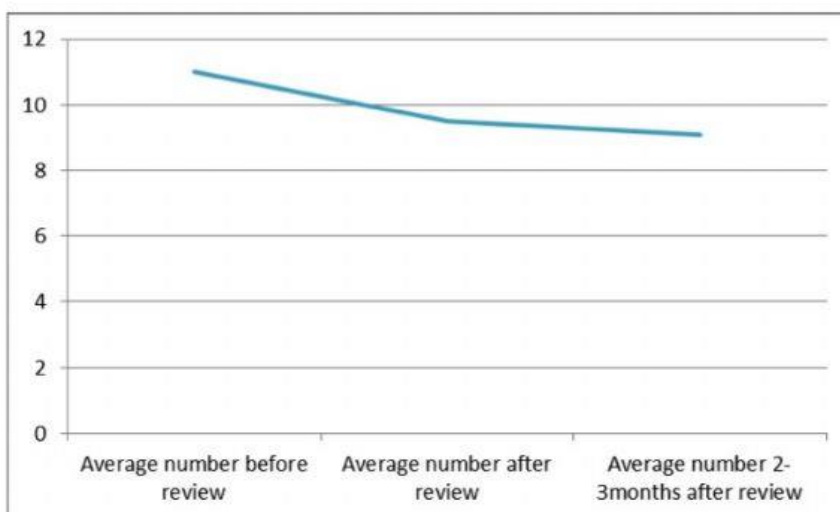

Follow-up data are currently being collected, including surveys with patients and doctors. The number of falls and hospital admissions three months after the review will be compared to the same time period one year earlier.

Conclusion

Results from this pilot study are beginning to suggest that family practice has a key role to play in reducing polypharmacy in the elderly. Family doctors are now taking part in an educational workshop, an alert is being set up on electronic records and annual 20 minute polypharmacy reviews for vulnerable people are planned.

Case Report: Approach To Tinea Incognito

Mehmet Ziya Gençer, Ezgi Kaçar, Gözde Nizamoglu, Reyhan Üstündağ, Seçil Arıca

Department of Family Medicine, Istanbul Province Beyoglu Association of Public Hospitals Okmeydanı Training And Research Hospital, Istanbul, Turkey

INTRODUCTION: Tinea incognito is a disease that gets the look of atipic form of mycotic infection, imitating many different dermatomes formed by misdiagnosing and giving improper topical, systemic steroids or immunosuppressive therapy. This form which named "Tinea incognito" or "steroid-modified tinea" may appear with different clinical forms after corticosteroid applications. In this case we demonstrate a patient who started topical corticosteroids application with misdiagnosis and after that insisting topical corticosteroids use on her treatment from doctors she see.

CASE: Forty-two-year-old female consulted to our clinic with severe itch, rash, redness that started at inguinal region and spreaded to belly region. Patients complaints is ongoing for 5 months and she first admitted to the pharmacy and given her klobetazolpropiyonat cream for itching. Later while she was out of town prescribed same medicine to a family doctor. Patient stated that given cream reduced itching and after stop using medicine itches increased and worsened. Patient related rise of complaints with "unfinishing "treatment. Patient has requested the re-prescription of the same medicine from our clinic "to be able to continue treatment". The patient has been informed and convinced to an examination. During examination erythematous papules and squamous plaques with unclear boundaries seen examination in the belly and around the inguinal region. From the anamnesis taken from the patient and clinical look disease thought as tinea incognita. Terbinafine 250mg/day, isoconazole cream (2 times a day) and terbinafine spray (2 times a day) started. In her supervision a week later lesions and complaints were seen reduced and totally disappeared in four weeks.

CONCLUSION: The history of tinea incognito case is fairly typical. As a result of using corticosteroids, immune system suppressed and at the beginning clinical signs depends on dermatophyte infection to become indistinct, rash disappeared but fungal infection gradually spread. Patients forced to use drugs repeatedly, and this becomes a vicious cycle. This clinic properties caused by steroids should be kept in mind by the family physician, also society should made aware of the drawbacks of using unscripted drugs.

Keywords: Tinea incognito, misuse of corticosteroid, mycotic infection

Self-Regulation Skills in Cigarette Addiction: A Case Report

Evrım Kardelen Dizdar, Makbule Neslişah Tan, Vildan Mevsim

Department of Family Medicine, Dokuz Eylül University, İzmir, Turkey

INTRODUCTION: Self-regulation involves being able to set goals, monitoring one's behaviour to ensure that it is in line with those goals, and having the will power to persist until goals are reached. Self-regulation skill is not a personal ability and specific processes need to be fulfilled. In literature, there are few studies about self-regulation and dependence, and are generally about alcohol and drug dependency. The effect of self-regulation skills on the treatment of nicotine dependence remains unstudied.

CASE: A 55-year-old male patient who had been smoking for 40 years admitted to DEUTF Family Medicine smoking cessation clinic with the reasons; considering health, being a good example to community. 80 pack-year is calculated with 60 pcs/day smoking. The alcohol consumption per week was 70+70ml. The patient had been suffering from hypertension and type 2 diabetes for a year and was taking Novorapid, Levemir and Wansaar Plus. System symptoms were observed normal in physical examination. No other evidence rather than cholesterol and triglyceride elevation (cholesterol 184, triglycerides 285) were observed in laboratory tests. Fagerstrom test for nicotine dependence score was 9 points, which showed the patient had a high dependence, while Self-regulation Questionnaire score was 139 detected as low. Appropriate treatment in flow diagram was administered which was specified in national health program. Bupropion and nicotine patch were recommended in treatment. Patient started medical treatment and quitted smoking on the date he preferred. With the routine visits and patient's

cooperation to treatment, the second month is over. He never smoked then, and went on treatment successfully. Self-regulation questionnaire score was detected 138 points at second and will be applied again on the third month.

DISCUSSION: Determining self-regulation capacity and developing methods to increase the level, will increase the chance of success in smoking cessation programmes and coping with other life problems.

Topical Treatment in Otologic Disorders – state of the art

Ana Sofia Rocha¹, Céline Raposo Gama², Sara Daniela Ferreira³, Sofia Maria Faria⁴

¹USF Modivas, ACES Póvoa de Varzim/Vila do Conde, Porto; Portugal

²USF Oceanos, ULS Matosinhos, Porto; Portugal

³USF Infesta, ULS Matosinhos, Porto; Portugal

⁴USF Lagoa, ULS Matosinhos, Porto; Portugal

Background & Aim

Otologic disorders are a common problem in primary care and its treatment is a Family Physician’s challenge. Topical therapy has many advantages however it appears that a large part of the patients are still treated with systemic antibiotics. This review aims to assess the current topical therapy recommendations for the most common ear diseases.

Methods

A systematic literature search was conducted at main research database, Pubmed and National Guideline Clearinghouse, of systematic reviews, meta-analyzes and guidelines, published between 2004 and 2014 in English, Portuguese, French and Spanish with the MESH terms “Administration, Topical” and “Ear disease”.

Results

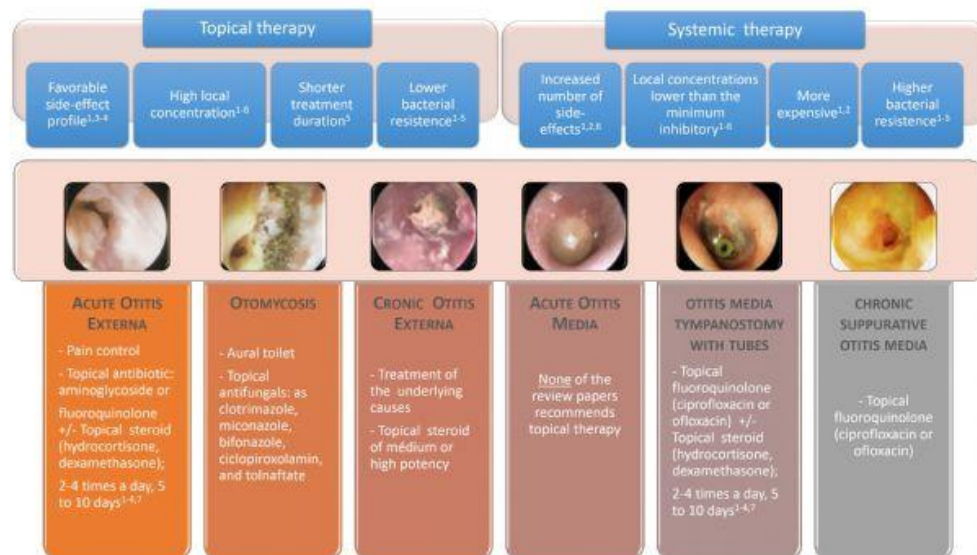

The reviewed papers demonstrate that topical therapy provides significant benefits in the treatment of outer ear pathology (external otitis and otomycosis) and middle ear (acute otitis media with tympanostomy tubes and chronic suppurative otitis media). None of these recommends topical therapy for acute otitis media. Considering the ototoxicity potential associated with other drugs, fluoroquinolones are assumed to be the agents of choice. The association with corticosteroids demonstrated several advantages.

Conclusions

Topical therapy is defined as first-line treatment in many otologic conditions. Despite recommendations it's not always the first choice in clinical practice over systemic therapy, contributing to bacterial resistance, increased number of adverse effects and longer duration of treatment.

Relation of serum Creatinine with result of D-Dimer

Jose María Fernandez Gonzalez¹, Pedro Guijo Gonzalez², Juan Jesus Rodriguez Vallejo³

¹HEALTH CENTER OF LA GRANJA-MANUEL BLANCO, DISTRICT JEREZ-northwest coast, HOSPITAL OF JEREZ DE LA FRONTERA.

²INTENSIVE CARE UNIT OF JEREZ DE LA FRONTERA

³HEALTH CENTER OF LAS DELICIAS DISTRICT JEREZ-northwest coast, HOSPITAL OF JEREZ DE LA FRONTERA.

Objective

To know the influence in patients with elevated levels of creatinine in relation to positive results of d-dimer (DD). - This is a retrospective study, from the Emergency Department, (DD) is requested in patients with high disease suspected thrombus-embolic, studying the positive values of these levels depending on the serum creatinine, and revising later with study of radiological image, the confirmation of the pathology.

Total of 1116 patients, lost 6.7 %, obtaining a subgroup of 670 patients with levels higher than normal ($>0.5\text{mg/L}$), with a value of DD means of 3.25 and a standard deviation of 6.16, windmills in intermediate levels of 3 or less (74.9 %) and high levels of 3 or higher (25.1 %), the value of mean serum creatinine was 1.11 mg/dl and a standard deviation of 0.94.

In patients with DD high, all of them underwent image test, we obtained a positive predictive value VVP of 14.1 %, with a diagnosis of 14.1 %.

Analyzing the results based on values of creatinine, reached a PPV of 14.3 % in the patients with normal levels of creatinine, in addition to a PPV of 14.5 % of patients in the subgroup of mild renal impairment and a PPV of 9.4 % in patients with moderate renal insufficiency.

Studying creatinine level, in which that value is > 3 , highlights a growing number of requests for evidence (53.7 %) compared with the total (37.6 %), with an increase in PPV from 38.3 % in the total, that if we divided in function of the three groups of creatinine, it would give us the following RESULTS: with normal kidney function VPP 40.6 %, mild renal dysfunction 41.9 % dysfunction moderate 9.1 %.

We got a positive correlation between serum creatinine and D-dimer: $r=0,109$, $p=0.005$

Keywords: thrombosis; d-dimer; creatinine

Virilizing Adrenocortical Carcinoma in a Premenopausal Woman: Case Report

Nazli Sensoy, Mehmet Yilmaz

Department of Family Medicine, Afyon Kocatepe University, Afyonkarahisar, Turkey

AIM: Adrenal cortical carcinoma is rare malignant tumor and with an annual incidence of about 0.6-1.67 cases per million persons per year. In this case, we are to show the role of primary care physician in approach of adrenal cortical carcinoma that presented as virilism.

METHODS: A review of the literature is made.

RESULTS: A 45 year woman came with a complaint of hirsutism. Detailed history of the patient was taken. There were irregular menstrual bleeding of 4-month duration and hirsutism of 6-month duration. Physical examination of the patient was elevated blood pressure. There were 8-10 scored hirsutism and androgenic alopecia. Family history of hirsutism detected. On local examination there was no mass detected in lumbal region. Blood investigations, liver function and renal function tests were within normal limits. Plasma total testosterone level and 17 OH Progesteron level were elevated. There was hyperandrogenemia. We thought that this case could be an androgen secreting adenom, pheochromocytoma, Cushing syndrome or adrenocortical neoplasm presented with virilism. We consulted to our endocrinology clinic. A spiral computed tomography of the abdominal showed a mass of size 6 x 8 cm in left surrenal gland and 16 mg dexametazon suppressed the cortisol level. Patient underwent surgical excision of mass, histopathology of the mass confirmed adrenocortical carcinoma. Then referred to oncology clinic with the clinical diagnosis of metastatic adrenal cortical carcinoma. She visits her oncologist after the treatment currently.

CONCLUSION: This case shows that assesment of patient's medical and laboratory history will provide for the primary care physicians' care coordination and advocacy in their primary care management, also longitudinal continuity for the person-centered care.

From Space to Family Medicine

Pedro Caetano¹, Carolina Martins Moreira²

¹USF Nova Via - CHVNG, Porto, Portugal

²CHP - Serviço de Fisiatria, Porto, Portugal

BACKGROUND and AIM:

Scientists and physicians can use an unique space based platform from which to conduct groundbreaking medical research. Since 2000, the International Space Station (ISS), is used as an orbiting laboratory for many kinds of research, establishing a strong relationship between health care research and space programs effort.

There has been an enormous investment from Space agencies, particularly from NASA in aerospace medicine, regarding the alterations that human physiology has in space environment and there are many medical problems that space missions have in common to a family doctor daily usual diseases as, increased infections rate, weight-bearing bone and muscles deterioration, fluid redistribution, glaucoma or increased cancer risk.

METHOD:

Bibliography research, collected data and lived experience from the author's internship in aerospace medicine in NASA-UTMB.

RESULTS:

Without gravity to help orient them, astronauts experience changes in their sense of balance. Studying this phenomenon yields insights into dizziness, vertigo, balance problems and disorders related to the inner ear. Observing the behavior of microbes and other organisms in space can generate insights into the behavior of organisms on earth, and lead to better understanding of infectious diseases and the immune system's response to them.

Studies regarding the influence of microgravity in musculoskeletal system, namely bone and muscle loss, showed the importance of exercise when compared to bisphosphonates, isolated and established some protocols that are being used on earth.

CONCLUSIONS:

Research on the space station will help generate better understanding of how weightlessness affects the bone, muscle, inner ear systems and microbes behavior in immune system. Our health, medical knowledge and capabilities have grown greatly because of space exploration and the equipment and techniques developed for it. FM can take advantage from research and innovation and use this cutting edge information to treat patients.

The Clinical and Morfoligical Picture of asytmomatic HBsAg carriers in Fachklinik Furth im Wald-Germany – Medical Cener Laza.K.Lazarevic Sabac-Serbia

Maja Canak¹, Snezana Mihailovic²

¹Fachklinik Furth im Wald-Germany

²Meical Center Laza.K.Lazarevic Sabac-Serbia

Background &AIM: Viral Hepatitis acute or chonical course is common infectious disease which characteristic inflammation and necrosis liver,and may be couesd by meny viruses.Aim of this paper is to show the incidence of different clinical form from HBV infections by asymptomatic carriers HBsAg,monitoring of Laboratory results,viral markers,ultrasound diagnostic and histopathological findings and significance of histopathologically verifications disease.

METHOD: In the Group of patients studied was 54 asymptomatic carriers disease 35(64,8%)men,19(35,2)women.The average age was 36,8+/- 9 years.The most of Patients belongs to age 21-30 years.

RESULTS: The Analysis of our findings of a small number of respondent had a " surrogate" markers of active viral replikations 9(16,7) but at 14(35,9)were founded histopathological picture of chr.Hepatitis which means that even in a number of HBeAg negative Patients active virus replikations takes place and the disease progresses by 1/3 asimptomatically holders HBsAg.By this Patients is blood testing from HBV DNA-positiv which representing the most reliable marker active virus replication.By asimtomatic carriers there is a correlation between histopathological findings and transaminase,this suggests that the routine control of transaminase is important parameter in assessing liver damage,or at leatest a guide line for liver biopsy.Determination of bilirubin to assess liver damage in asymptomatic HBsAb holders is consider it unnecessary.

CONCLUSIONS: As in our environment growing number of HBeAg negative patient,we conclude that the findings of HBV DNA as the most reliable markers of active viral replication would be useful to do in these patients and that is by asimpt.holders HBsAg necessary liver biopsy and histopathological verification of disease.

Primary Erythromelalgia is a uncommon vasomotor syndrome localized on hands: Report of Clinical Case

Cristian Ayala Carreño, Sara Sánchez Belmonte, Ester Muñiz Quinto, Engracia Costa Atienza, Gloria Padullers Furriols, Anna Forcada Arcarons, Alícia Díaz Pilco

Primary care center. ABS Manlleu, Barcelona. España

Description of the case

57 year old woman with a history of thalassemia minor with no other relevant history who consulted for painful burning sensation, accompanied by erythema, acral paresthesias, triad of erythema, increased temperature, and intermittent pain in the upper extremities for 3 years.

The patient was treated with anti-inflammatory drugs and corticosteroids without notice improvement

Exploration and complementary tests

Upper extremities: Both hands with erythema, swelling, a painful deep-aching of the soft tissue and tenderness, along with elevated skin temperatures in affected area.

Analysis: CBC compatible with thalassemia. Other laboratory results were nonspecific.

Differential diagnosis

Fabry disease, Peripheral neuropathy, Raynaud phenomenon, Vasculitis, Cellulitis, Reflex Sympathetic Dystrophy, Palmar Erythema, Neural Compression, Occlusive Vascular Disease, Mercury Poisoning, Autoimmune disorder, Polyneuropathy, Osteomyelitis and Sciatica.

Clinical features

The diagnosis of erythromelalgia is clinical and is set with the manifestation of 3 major and 2 minor criteria. They are major criteria: a) the evolution of paroxysmal crisis, b) the burning pain, c) erythema; are minor criteria: a) the exacerbation of seizures with heat, b) improvement in the cold, rest or both, c) local hyperthermia during the crisis, d) the favorable therapeutic response with acetylsalicylic acid (ASA).

Conclusions

Living with erythromelalgia can reduce the quality of life resulting in the inability to function in a work place, lack of mobility, depression, and is socially alienating. As with many rare diseases, many people with EM end up taking years to get a diagnosis and to receive appropriate treatment. To get a diagnosis can take many months and the patient will often have seen many specialists before finding out what is wrong with them.

{"Hospitalizations due to warfarin overdose within a year in Ankara Numune Hospital and place of primary health care in follow-up"}

Elçin Katı¹, Duygu Ayhan Başer², İrfan Şencan¹, İsmail Kasım¹, Rabia Kahveci¹, Adem Özkara³

¹Department of Family Physician, Ankara Numune Training and Research Hospital, Ankara, Turkey

²Department of Family Physician, Derince Public Health Center, Kocaeli, Turkey

³Department of Family Physician, Hitit University, Çorum, Turkey

"BACKGROUND-AIM: Thrombotic diseases are one of the most common fatal disease groups, therefore treatment and prophylaxis of these diseases become important. Warfarin with a narrow therapeutic range is used in the prophylaxis and treatment of many diseases.

The purpose of this study is to evaluate the management of hospitalized patients who use warfarin, whom INR values are 4 and above, and the level of primary care follow-up.

METHOD: This is descriptive and retrospective study. All patients take warfarin, applied to our hospital for any reason between November2012-October2013 and whom INR value is at least 4 included. 187 patients detected. The patients were evaluated according to sociodemographic features, complaints, duration, doses, indications, INR values, comorbid diseases, blood transfusions, follow-up periods. We contacted with 116 patients by phone and asked the duration of warfarin use, follow-up, primary health care applications, the clinic which set-up doses, educations about warfarin.

RESULTS: 53.5% of 187 patients were male and 46.5% of patients were women. Most of complaint to the hospital was bleeding(22.4%). INR value was between 4.5-6.4. 31.6% of the hospitalized patients had blood transfusions. 116(62%) patients were discharged and 71(38%) patients were excitus. The indications for use warfarin were atrial fibrillation 30.5%, cerebrovascular event 12.8%, deep vein thrombosis 7.5%, pulmonary thromboembolism 5.9%. The cardiology started warfarin to 38%(71) of patients. 12,3%(23) of patients were admitted to the primary health care for warfarin dose adjustment. Patients followings were done by cardiology, home health services, cardiovascular surgery and neurology(16%, 6.4%, 5.9%, 4.3% respectively). The number of patients educated for warfarin use was 25(13,4%).

CONCLUSION: We determined that the management of thrombosis should done in primary health care like other diseases with high morbidity and mortality. Management of these cases must be performed by multidisciplinary approach and family physician has to be a part of it."

Evaluating Family Functioning using FACES III in a Korean Primary Care Family Cohort

Eunjeong Choi¹, Hye Won Park², Sung Sunwoo³

¹International Healthcare Center, Asan Medical Center, Seoul, South Korea

²Department of Pediatrics, Seoul National Bundang Hospital, Seongnam, South Korea

³Dept. of Family Medicine, Asan Medical Center, Univ. of Ulsan College of Medicine, Seoul, South Korea

BACKGROUND: The family, a basic unit of social relationships, share genetic, physical and psychosocial environments. Therefore, it is considered to have an impact on the development, management and prevention of many health problems. If we can assess family functioning with objective values and observe the incidence of a disease in a prospective setting, we can prove whether the family plays a role in the development of a disease. By using a standardized FACES III (Family Adaptability and Cohesion Evaluation Scale), this study is aimed at investigating the family functioning of Korean couples METHODS: From April 2009 to April 2011, 1,034 subjects visited 26 family physicians in 23 different hospitals and were enrolled in a 'Primary Care Family Cohort'. They were all couples older than 30 years.

Family functioning was evaluated by FACES III, a 20-item scale standardized in Korean. Using the results of this questionnaire, we calculated the norms of cohesion /adaptability scale and their distributions. We also distributed them and compared with the Circumplex model devised by David Olson. RESULTS: 1,027 subjects completed filling out FACES III. The mean of cohesion scale was 34.8 and that of adaptability scale was 24.0. Women had higher adaptability and cohesion scores than men. The younger also rated higher adaptability and

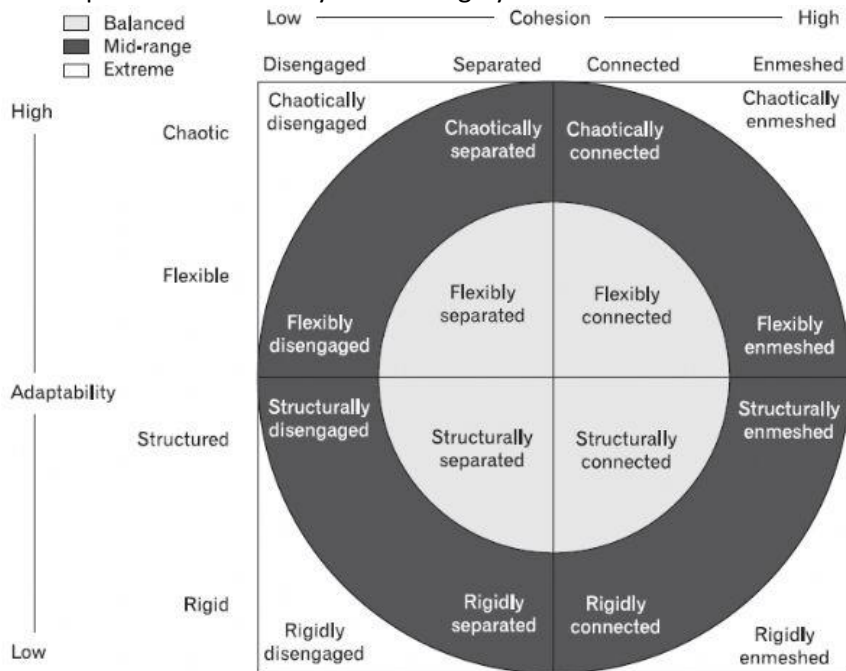

cohesion scores than the elder. The gross distribution of cohesion and adaptability scores of Korean couples in this study was not a circumplex but a crescent or a semi-circumplex.

Family functioning of Korean couples showed that the adaptability scale has two extreme values with a normal distribution. But the cohesion scale showing skewed distribution to the left is due to different family value on cohesion in Korean culture.

CONCLUSION: This led us to the conclusion that Korean's cohesion scale satisfies linear hypothesis rather than conventional curvilinear hypothesis.

Analysis of reasons for temporary deferral of blood donors

Hamza Aslanhan, Necmi Arslan, Erkan Kibrisli, Ahmet Yilmaz, Mehmet Halis Tanriverdi
 Department Of Family Medicine,Dicle University Medical Faculty,Diyarbakir,turkey

AIM: We aimed to determine the refusal reasons that lead to temporary deferral of blood donation.

METHOD: The files of 1663 temporarily refused blood donors among the 54429 people, who applied to Dicle University, Medical Faculty, Blood Center between 2012 and 2014, were retrospectively reviewed. The selection of blood-donors and deferral criteria were based on National Blood and Blood Products Guide published by Turkish Republic, Ministry of National Health in 2011. Chi-square test was performed using SPSS15.0, and $p < 0.05$ was accepted as statistically significant.

RESULTS: Among the 54429 blood-donor candidates only 1663 people (0.03%) were temporarily refused during the 3 years period. Of these candidates, 1565 (94.1%) were male, and 98 (5.9%) were female. The mean age of them was 31.76. Among the refusal reasons, the most frequent three reasons were low Hb/Htc level, vascular access problem and medication respectively (Figure 1). The refusal reasons were evaluated by comparing four age groups (18-24, 25-39, 40-54 and ≥ 55), and statistical differences were found ($P < 0.05$) (Table 1). In addition, the rates of rare reasons responsible for the refusal of 340 donors (20.4%) were given in Figure 2. Among these rare reasons, the most common three reasons were having a chronic disease, previous donation within 3 months and operation history.

CONCLUSION: Selection of appropriate blood donors is crucial to prevent the hazardous blood transfusion. It was observed that only a small proportion of all blood donor candidates has been temporarily deferred. Therefore, more attention should be paid to the medical history and physical examination of blood donors, and education programmes should frequently be organised for health personnel. As “Dental caries/treatment” was determined among the common reasons, although we did not encounter this reason in the literature, this suggests that we need to increase public awareness on this issue.

Just a musculoskeletal pain? A case report of Pancoast Tumor with Horner Syndrome

Manuel Maria Barbosa¹, Céline Raposo Gama²

¹USF Caravela; Unidade Local de Saúde de Matosinhos, EPE.

²USF Oceanos; Unidade Local de Saúde de Matosinhos, EPE.

BACKGROUND & AIM: Musculoskeletal pain is a frequent complaint at primary health care. The Family Physician (FP) has an important role in the differential diagnosis and ruling out potentially severe conditions. The aim of this case report is to emphasize that a commonly benign presentation may have a complex outcome.

METHODS: A case report based on patient interview and electronic clinical records. A bibliographical research was conducted for clinical review.

RESULTS: A 63-year-old man, with personal history of dyslipidemia, overweight, and former smoker (fourteen months tobacco-free; 94 pack-year). Over two weeks frequently recurs to medical care with complaints of right upper limb pain with moderate functional limitation. There was a history of trauma associated. The initial physical exam showed painful right upper limb edema, especially at the elbow. There was no significant improvement in symptoms with analgesia prescribed. By his initiative the patient did a chest radiograph that showed an opacity in the upper third of the right lung. Presented to an emergency appointment with his FP. The physical findings at this point were right unilateral ptosis and miosis, edema of right side of the face, pain and edema of right upper limb and an exuberant right supraclavicular mass. The patient was referred to Secondary Health Care for study and therapeutic decision. The diagnosis was a Pancoast's tumor with an associated Horner Syndrome. The FP maintained the continuity of care with his patient, that was eventually referred to a Palliative Care Unit.

CONCLUSION: The FP, being the point of first medical contact within the health care system, is responsible for the provision of longitudinal care. He is a fundamental agent in the efficient use of health care resources working with other professionals. Finally, this case highlights the importance of considering non-musculoskeletal causes of upper limb pain.

Painful subcutaneous nodules in HIV-pregnant woman

Paola Lievano, Alvaro Irigoyen, David Idoipe, Jose Antonio Ibañez, Carlota Canet, Oscar Zepeda, Miguel Lopez Del Pueyo, Sara Lainez, Laura Urieta, Jesus Maria Tenias, Amparo Cantin, Miguel Rivas, Violeta Alastrue, Santiago Letona

Department of Community & Family Medicine. Sector III. Hospital Clínico Universitario Lozano Blesa, Zaragoza, Spain.

Background & Aim

HIV patients with antiretroviral treatment are not uncommon in primary care. However, pregnancy increases complications. Is a major challenge to control risk factors while using antiretroviral and detection of disturbance and comorbidities. It is critical to be alert of warning signs that allow us to early diagnosis and treatment.

Method

32-year-old African-American woman was diagnosed with HIV five years ago (Category A: asymptomatic, > 500/ μ L CD4+ T-cell count) currently 28 months pregnant. Presents painful and red subcutaneous nodules located on the posterior aspects of the lower legs two weeks ago. Due to suspicion of erythema nodosum, multiple tests are requested.

Results

A positive Mantoux (vesicle and erythema 25mm). A chest radiography and echography were normal. Sputum smear and culture were performed with negative results. Biopsie of the subcutaneous fat demonstrated a lobular panniculitis.

Conclusions

Erythema induratum of Bazin (EIB) are a granulomatous lobular panniculitis that may develop in association with tuberculosis^{1 2}. Young women are commonly affected³. Treatment of EIB is the same as that for systemic tuberculosis. HIV-pregnant women who are suspected of having TB disease must be treated without delay. In contrast to EIB, lesions of erythema nodosum are more likely to occur on the anterior legs and show a septal panniculitis⁴.

Is important to know which antituberculosis drugs are contraindicated in pregnant women (Streptomycin, Amikacin and Fluoroquinolones). Rifampicin is a potent inducer of liver enzymes and lowers the blood levels of Nevirapine, should not use together.

In this case treatment was well tolerated and leaving areas of hyperpigmentation.

Treating pregnant women with both HIV and TB can be challenging frequently due to drug interactions of the medications needed for both diseases. Is necessary emphasize the role of primary care interventions.

Teledermatology... Effective or theory?

Joana Palmira Magalhães

Centro de Saúde Miranda do Douro - ULS Nordeste

Background & AIM: In recent decades the worldwide incidence of skin cancer has increased. In this context, teledermatology becomes a tool more useful. With resource to doctors, communications and internet technologies, teledermatology allows easy care of population's skin.

We seek to show a case of how teledermatology can work in primary health care,

METHOD: Male, 76 years, with history of dyslipidemia and hypertension, presents to the primary care with a skin lesion on the neck, that appeared 3 years ago. Described initially as a papule of reduced dimensions, with progressive growth, appearance of a central ulcer and easy bleeding. At the objective examination revealed a lesion 2 centimeter in its longest axis, raised edges and central crust.

It was sent a request (with the history and the images) for review by the dermatological teledermatology screening for the hospital of reference – Hospital de Santo António, with informed consent of the patient.

RESULTS: The answer was given on the same day of the request, with a therapeutic proposal: "The patient requires surgical excision (...) at the local hospital (...) or (...) at our institution. (...) suggests basal cell carcinoma." After the patient decided to receive treatment at Hospital de Santo António, subsequent contacts took place by e-mail, to speed up and solve the problem.

CONCLUSIONS: This case report is an example of teledermatology speed and cost-effectiveness. Allows impact reduction of distance and obtains a therapeutic approach without increase the waiting list. In addition, is a tool used by family doctors and dermatologists, in a faster diagnosis and a better health outcomes. Finally, teledermatology provides training through the exchange of experiences among professionals.

Keywords: teledermatology, diagnosis, skin, cancer

Lesion with raised edges and central crust on the neck.

This lesion was the reason why the patient went to a consultation and the motive to request the teledermatology screening.

Job Satisfaction of Primary Health Care Professionals in Turkey and Their Exposure Levels to Violence

Seyhan Hidiroglu¹, Ozlem Tanriover², Melis Tosun¹, Cem Armağan Turan¹, Burcu Sena Günaydın¹, Büşra Eser¹, Kaug Myat Htoo¹, Melda Karavus¹

¹Department of Public Health, Marmara University School of Medicine, Istanbul, Turkey

²Department of Family Medicine, Yeditepe University Faculty of Medicine, Istanbul, Turkey

Background and AIM:

Job satisfaction can be affected by various factors such as financial compensation, opportunity for advancement, relationship with the supervisor, and the job security in workplace. On the other hand, the incidence of workplace violence against health care workers is reported 16 times higher than that of any other professionals.

The aim of this study was to determine the correlation between workplace violence and job satisfaction of primary health care professionals in Turkey.

METHOD:

In this descriptive cross-sectional study a questionnaire was administered to 143 primary health care professionals. The questions asked about workplace violence and their reactions against it, while the job satisfaction was asked using "Minnesota Job Satisfaction Scale".

RESULTS:

Sixty-five percent (n=92), was exposed at least once to workplace violence throughout their career. Majority (82%, n=117) of the sample were exposed to psychological harm including verbal assaults, while 20% (n=28) of the sample were exposed to physical aggression, during the last year. Most of them had never been trained how to prevent the workplace aggression or how to react when it took place. Seventy percent (n=88) of the participants who showed great anxiety in case of violence, had been exposed to workplace violence at least once throughout their career (p<0,05). The ones who had been exposed to workplace violence at least once were less satisfied with their current profession than the ones who had never been exposed to violence before (p<0,05).

CONCLUSION:

Overall, the results showed that the majority of primary health care professionals had been exposed to workplace violence. Their anxiety levels due to the violence lead them to doubt whether the standards for workplace security are sufficient or not. The findings also pointed out the fact that the exposure to workplace violence affects the job satisfaction in a negative way.

Keywords: Violence, job satisfaction, primary health care professionals

Minor surgery referrals at a rural/urban health center

Gloria Inmaculada Mestre Reoyo, Maria Rosario Rosillo Rein, Nayade Jorge Martin, José Carlos Perez Sánchez, José Ángel Sánchez Ortiz, Juan Carlos De Sola Jurado

Andalusian Health Service

OBJECTIVE:

Test the level of coincidence between final diagnosis by one's family healthcare professional that lead the patient to undergo minor surgery through the health center, and the post-surgery diagnostics that follow.

MATERIAL-METHODS:

Transversal descriptive study patients that were recommended minor surgery. Data obtained from clinic archives regarding the medical history of each patient. Said data was divided according to gender and diagnostic coding.

RESULTS:

Of the 238 patients sent to minor surgery, 203 kept their appointments, 87 men and 116 women. Of them, only 8 had diagnosis of derivation: 6 papillomas, 1 of papilloma / eccema and 1 with an ingrown nail. The minor surgery center only coincided with 2 papilloma diagnosis. After passing through diagnostical procedures the 203 patients were diagnosed as such: 6 abscesses, 6 soft corns, 2 fibroids, 11 lipomas, 7 nevus, 10 papillomas, 1 rubi point, 1

hemosiderotic cyst, 1 keratoderma, 9 seborrheic keratoses, 4 trichilemmal cysts, 107 warts.

12 samples from the minor surgery were sent to anatomical pathology, and were diagnosed as follows: 1 Bowen, 1 melanoma, 2 basal cell carcinomas, 3 dermatofibromas, 2 trichilemmal cysts, 3 blue nevus.

ARGUMENTS / CONCLUSION:

Improvements must be made to the regulations regarding referrals to de minor surgery, including possible diagnosis.

It would have to involve discovering why 35 patients with scheduled appointments at the minor surgery didn't attend as planned, when the average waiting time for screening consultation is 1 week, for surgery with electric scalpel 1 week and for surgery with cold scalpel 3 weeks.

It involves medical treatment with minimum delay that solves various problems and is less inclined to admit patients in to the hospital.

probiotics supplementation and its efficacy in helicobacter pylori eradication. there's evidence?

Joana Andrade Barros¹, Lisete Aires Silva¹, Marta Sousa Santos³, Simão Costa Martins², Cilia Nogueira², Sabrina Pedone¹, Sónia Marcelo¹, José Verdelho Alves³

¹USF Terras de Souza, Paredes, Portugal

²USF Hygeia, Lixa, Portugal

³UCSP Boticas, Boticas, Portugal

Background & AIM: Helicobacter pylori (Hp) colonizes the gastric mucosa and it's associated with some pathologies, from chronic gastritis to gastric cancer. Hp eradication (HpE) may reduce the risk of developing this cancer and therefore, it should be a primary objective. The commonly used treatment may have several side effects, contributing to its failure. Some studies refer an increased benefit when the recommended treatment is associated with probiotics, revealing itself an useful tool in the HpE treatment complementarity. The aim is to gather evidence on the increasing efficiency in HpE, when combining probiotics to the eradication therapy.

METHODS: There were researched guidelines, systematic reviews, meta-analyzes and randomized controlled trials (RCT), from the last 10 years, in Portuguese and English, using the MeSH terms: "Helicobacter pylori" and "Probiotics". When necessary, the strategy was adapted to each database. To assess the level of evidence and strength of recommendation, Strength of Recommendation Taxonomy of the American Academy of Family Physicians was used.

RESULTS: There were found 236 articles, which 19 selected: four meta-analyzes, fourteen randomized controlled trials e one guideline. The meta-analyzes and the guideline refers that an increase in the HpE rates could exist with the use of probiotics. However, the included randomized controlled trials, conclude that the addition of these probiotics doesn't increase eradication rates, but showed higher tolerance to adverse effects.

CONCLUSIONS: The probiotics addiction to HpE therapy, with the purpose of achieving greater efficiency, has been under discussion in the present. Due to the results heterogeneity more studies are needed, in order to extrapolate to the population in a more sustained way. In a more consistent way, there seems to exist a beneficial effect in side effects redution, that for the greater adhesion to therapy, may lead to greater success in the eradication.

Keywords: Helicobacter pylori; Probiotics.

Awareness and Opinion About Complementary and Alternative Medicine Amongst Healthcare Professionals

Saba Sağlıker, Nazlı Çelik, Cansu Öztürk, Burcu Demirbaş, Dilek Toprak

Şişli Hamidiye Etfal Training and Research Hospital Department of Family Medicine, İSTANBUL/ TURKEY

AIM: Complementary and alternative medicine (CAM) consists of the ever growing and popularizing range of therapeutic approaches. This study focuses on the awareness and opinion of healthcare professionals about complementary and alternative medicine.

METHODS: This research was conducted on 264 healthcare professionals. A 3-point Likert type scaled questionnaire about the knowledge level and opinion of the participant about 13 different complementary and alternative medicine approaches and socio-demographic characteristics were recorded. Data was analyzed via Chi-Square T test and frequency analysis using SPSS v20.0.

RESULTS: 143 (54.2%) of the participants were women, and 121 (45.8%) were men. Of these participants; 49 (18.6%) were midwives, 141 (53.4%) were resident physicians, and 74 (28%) were specialist. 174 (65.9%) had <5 years of clinical experience. The age average was 30.26 ±7.15. The most (n=129;48.9%) self-performed method was prayer therapy. The most common recommended therapies respectively were prayer (n=155;58.7%), massage therapy (n=145;54.9%), and nutrition therapy n=130;49.2%). Participants mostly (n=134;48%) requested nutritional therapy to be added to the curriculum; Especially females (p=0.000). Similarly, females applied prayer technique more than men (p=0.000). Most of the participants got educated on prayer (n=25;9.5%) and nutrition therapy (n=15;5.7%). While residents self-applied prayer more (p=0.000), and suggested most as well (p=0.000), they did not suggest prayer therapy education to be added to the curriculum (p=0.000). Residents believed in the application and use of nutrition therapy significantly more than midwives and specialists(p=0.005).

CONCLUSION: Today CAM are becoming more warm and interested. If CAM are added to the curriculum of medical faculties, physicians and the patients would use the method properly.

Keywords: Complementary medicine, Alternative medicine, nutrition therapy, prayer technique, therapy techniques

Eating Habit and Characteristics of Residents at Şişli Hamidiye Etfal Training and Research Hospital Family Medicine Clinic

Saba Sağlıkler, Sibel Karaman Tunç, Dilek Toprak

Şişli Hamidiye Etfal Training and Research Hospital Department of Family Medicine

INTRODUCTION: Eating disorders are both physical and psychosocial conditions that emerge from self-conscious thoughts about ones eating habits, weight, and visual image. In this report, eating characteristics of family medicine residents are taken into consideration.

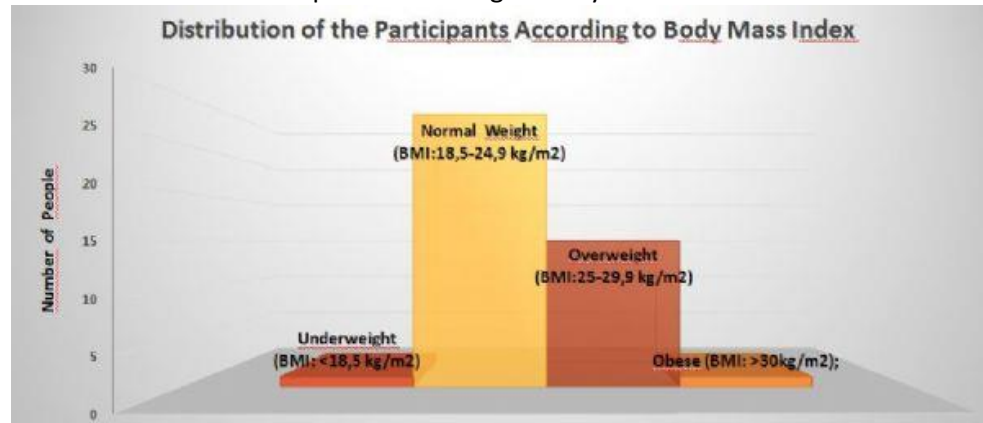

METHODS: Out of 54 residents working at Şişli Hamidiye Etfal Training and Research Hospital (ŞHETRH) Family Medicine Clinic, 45 were included in this study. Socio-demographic information data and EAT-40 eating characteristics scale results were recorded. Data was analyzed by Chi Square Test and frequency analysis on SPSSv20.0; $p < 0.05$ was considered significant.

RESULTS: Among 46 participants 32(71.1%) were women, 13 (28.9%) were men. While the average age was $28.48 \pm 2,07$; 30 (66.7%) of them were over 30 years old, 26(57.8%) married, 28(62.2%) participants had normal BMI and 31(68.9%) were living with their families. There were 21(46.7%) participants who had night shifts; 9(20%) of the participants had chronic disease. Alcohol consumption was observed in 32(28.9%) participants and there were 5(11.1%) smokers. According to their EAT-40 score, 5(11.1%) of the participants had moderate-high risk in eating disorders; 68.9% spent more than 500 TL/month for their kitchen expense. There were 24(53.3%) participants who preferred to eat outside at least 4/week. Participants who had normal BMI, rarely felt anxious after having dessert($p=0.016$), and never ate after when they felt hungry ($p=0.000$). Women are more pleased to try sweet, fat rich foods than men($p=0.023$), and preferred to not eat alone($p=0.043$). 15 (78.9%) single participants had regular weight, while 13(50%) of married participants were overweight and did not prefer diet food ($p=0.012$).

CONCLUSION: Despite the fact that eating behaviour is determined by multi-factors, it is mainly driven by person's ability to reach and consume the nutrition, and their willingness of staying healthy. Environmental factors always regulate the result. Regarding working conditions and hours, eating characteristics of residents are evident, however future analysis are needed.

Magnesium and Muscle cramps – Which evidence?

Teresa Bastos, Marta Guedes, Lourdes Sousa

UCSP Sul, Oliveira de Azeméis, Portugal

BACKGROUND: Muscle cramps are involuntary contractions, sudden and painful, usually of the posterior muscles of the leg, which can last seconds to minutes. The only pharmacological intervention with proven efficacy for its treatment is quinine (with serious side effects); however, magnesium supplements have been widely used for this purpose.

AIM: Review existing evidence regarding the benefit of magnesium supplementation in reduction of muscle cramps (number, duration and frequency) on non-pregnant adults.

METHODS: Research on Medline and medical sites based on evidence; articles published between January 2004 and February 2015; English, Spanish or Portuguese; keywords "muscle cramps" AND "magnesium". It was used the Strength of Recommendation Taxonomy scale (SORT) of American Family Physician to evaluate the levels of evidence (LE) and strength recommendation (SR).

RESULTS: Of the 383 articles found we included 6 articles, 2 systematic reviews (SR), 2 guidelines and 2 randomized controlled trials (RCT).

According to an SR, the differences in frequency and duration of muscle cramps between the intervention group (magnesium) and the placebo group were not statistically significant (LE 1). In another SR, the administration of magnesium showed mixed results (LE 2), by referring that magnesium supplements may be useful in the prevention of muscle cramps (SR C).

Guidelines said that magnesium supplements are unlikely to be effective in the treatment of non-pregnant adults muscle cramps (SR C).

In RCT it was found a reduction, not statistically significant, of the number of muscle cramps in the intervention group (magnesium) compared with the placebo group (SR 1). The severity and duration of muscle cramps remain unchanged between groups (LE1).

CONCLUSIONS: We can conclude that it is unlikely that magnesium helps to prevent muscle cramps in non-pregnant adults (SR C), but will take more studies to be able to draw definitive conclusions.

to know the non-invasive mechanical ventilation

Jose María Fernandez Gonzalez¹, Pedro Guijo Gonzalez², Hector Leonardo Lugo Ramos¹, Juan Jesus Rodriguez Vallejo³

¹HEALTH CENTER OF LA GRANJA-MANUEL BLANCO, HOSPITAL OF JEREZ DE LA FRONTERA.

²INTENSIVE CARE UNIT HOSPITAL OF JEREZ DE LA FRONTERA

³HEALTH CENTER OF LAS DELICIAS DISTRICT JEREZ-northwest coast, HOSPITAL OF JEREZ DE LA FRONTERA.

Non-invasive mechanical ventilation (VMNI) has a fundamental importance in many vital and urgent pathologies. In Primary care, Family Doctor can work in the Emergency Room and for this reason, we need to know the management and usefulness of the VMNI. It is for this reason that we consider important to analyze the epidemiological characteristics and effectiveness in patients that we prescribe VMNI in emergencies.

Descriptive study conducted in the area of emergency care in patients where employment in the area of VMNI observation during a period of 6 months. Qualitative variables were age, sex, APACHE II, personal history, cause of start of VMNI, cases in which i need invasive mechanical ventilation (VMI) and mortality. The data were analyzed using the statistical program SPSS, version 22.0

There were 69 patients with a mean age of 64 years, with 54% of men and 46% women. The Apache II averaged 19.2 points. The 55% of the signs was for heart failure(IC), 29% of respiratory infection (IR), and 5% in hypercapnic encephalopathy.

In the 41.9 % of the cases it was necessary the VMI,remain effective the VMNI in 58.1 %. The average mortality found was 19 %.

41% Of failures, they had respiratory infections concomitant.

CONCLUSIONS:

The VMNI presented a high rate of effectiveness and it is a good tool in the emergency area.

In our series, the main indication of VMNI was heart failure, followed by respiratory infection, being the most prevalent factor arterial hypertension.

The main failure of the VMNI is associated with respiratory infection.

Studying Hyperlipidemia in diabetic patients in a rural area of Crete

Theodoros Vasilopoulos¹, Georgia Arseni², Nikolaos Kontarakis¹, Eirini Trachanatzi², Cornilia Dimitriadou², Georgios Modinakis²

¹Health center of Ag.Barbara, Herakleio,Crete, Greece

²Venizeleio Gen. Hospital, Herakleio,Crete,Greece

BACKGROUND-AIM: Diabetic patients in Greece today account for 8-9%. Specialists estimate that the percentage is higher, since many people are unaware that they suffer from SD. WHO estimates that in 2030 in Greece, the number of diabetics will rise to 1.08 million from about 853 000 in 2009. The macroangiopathy is the most common cause of death in diabetics, rising to 74%. The purpose of our study is to investigate the prevalence mainly of hypertriglyceridemia and pathological values of LDL cholesterol among diabetic patients in a rural area of Crete.

METHOD: 281 diabetic patients were studied, the year 2014, of whom 172 women and 109 men. The concentrations of total cholesterol, HDL and triglycerides were measured by enzymatic colorimetric method in biochemical analyzer BT300 TARGA of A.Menarini Diagnostics. The LDL cholesterol value was calculated based on the formula $Ldl\ levels = Total\ cholesterol - (Triglycerides\ levels / 5 + HDL\ levels)$. Values of triglycerides $>150\ mg / dl$ and LDL cholesterol $>100\ mg / dl$ were considered abnormal.

RESULTS: Ninety-nine (35.2%) diabetics, of which 61 were male, were found to have elevated levels of total cholesterol. Seventy-eight (27.7%) diabetics, of which 49 women were found to have elevated triglycerides levels, while 17 (6.04%) had abnormal values in both parameters, of which 12 were men. Pathological LDL cholesterol values were found in 46 (13.37%) diabetic patients of which 12 were women.

CONCLUSIONS: In our region, the prevalence of diabetes is higher in women. Women with diabetes present more often with hypertriglyceridemia, whereas diabetic men present with hypercholesterolemia. The high frequency of hyperlipidemia in patients with diabetes entails greater risk for coronary heart disease than in the general population. Therefore, the main concern of general practitioners is to reduce the risk of severe atherosclerosis development.

P-1280

“Doctor my nipples are strange!” A case of hyperkeratosis of the nipple

Cátia Pereira Da Silva¹, Diana Vaz De Miranda², Olga Pereira³, Sofia Alves²

¹General Practice and Family Medicine, USF Aquae Flaviae, Chaves, Portugal

²General Practice and Family Medicine, USF São Nicolau, Guimarães, Portugal

³Dermatology, Centro Hospitalar do Alto Ave, Guimarães, Portugal

Background & AIM:

Primary health care is the first line of patient care and it is up to the general practitioner (GP) to recognize warning signs in time and investigate or refer for further study in other specialties. A dermatological complaint assumed to be a purely aesthetic problem, such as a nipple with hyperkeratosis, maybe the first sign of a serious condition. The hyperkeratosis of the nipple and areola is due to an excessive keratinization of the nipple and /or areola. This paper aims to remind that this condition may be idiopathic or secondary to other conditions and should not be ignored.

Methods and results (Case description):

Female patient, 27 years old, referenced to Dermatology by the GP because of the presence of a nipple keratosis in the last 10 years, refractory to topical treatments. Standing out from the personal history are an hay allergy and chronic sinusitis. Medicated since 21 years old with oral contraceptive (estrogene and progestative). On the physical examination the patient presents crusts on both nipples with seborrheic aspect, non pruriginous. The crust easily come off with bathing or with tweezers, without bleeding. The areolae were normal. Breast palpation was normal. No other relevant findings on physical examination. No family history of similar injuries was reported. Requested analytical study with hormone assay, breast ultrasound and histological analysis of the crusts removed from both nipples. Recommended hypoallergenic cleansing milk without fragrance.

CONCLUSION:

The treatment of hyperkeratosis of the nipple and areola depends if it is primary or secondary to other causes, such as hormonal changes or malignancy. This condition has affected the patient's quality of life in the last 10 years and by itself is a reason to consider in approach of the GP. The aesthetic complaint of this patient should have been investigated and oriented earlier.

Alcohol consumption habits of family medicine physicians in Slovenia

Marijana Nagy¹, Sara Nikolić²

¹Healthcare Center " Dr Adolfa Drolca" Maribor, Slovenia

²Faculty of Medicine University of Maribor, Slovenia

Background & Aim

Alcohol consumption, part of Slovenian tradition and culture, is one of the most important and most frequently discussed causes of different health, social and economic issues. The purpose of the research was to assess alcohol consumption habits among family medicine physicians in Slovenia. The goal was to obtain the data about alcohol drinking patterns of the family medicine physicians and to classify them to abstinent, low-risk drinkers, high-risk drinkers, hazardous drinkers or alcoholics.

Methods

The study was descriptive, cross - sectional one on the population of 700 family medicine physicians who were invited to complete the questionnaire: The Alcohol Use Disorder Identification Test (AUDIT-10), which was used as screening tool for identification of one`s drinking patterns. 53.2% (373) doctors completed the questionnaire and were included in the final analysis and evaluation.

Results

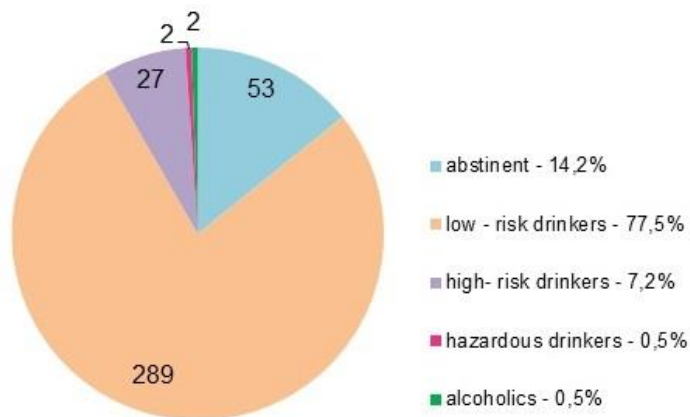

Analysis of the answered questionnaires showed that 53 (14.2%) of the doctors were abstinent, 289 (77.5%) were low-risk drinkers, 27 (7.2%) were high-risk drinkers, two (0.5%) were hazardous drinkers and two (0.5%) were alcoholics. The results revealed that the doctors with more patients and more monthly on-call hours drink more often, which was statistically significant.

Conclusions

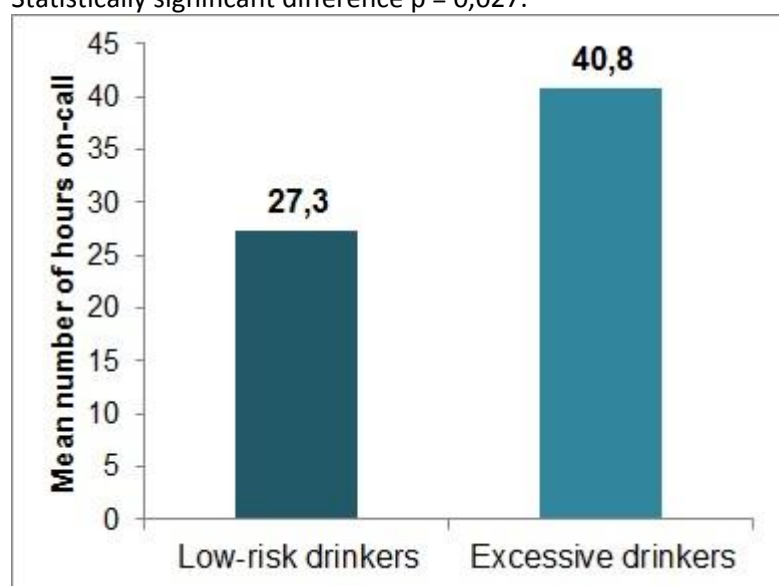

The research demonstrated that the alcohol consumption habits of family medicine physicians were comparable with those of general Slovenian population. 91.7% of the surveyed doctors were abstinent or low-risk drinkers. 8.2% of doctors were excessive drinkers, which represents an important risk-factor for low quality, unsafe and unprofessional clinical practise. Also, it may prevent one to deal properly with patients` drinking problems.

P-1282

Sleep-Related Painful Erections Following Sexual Intercourse

Pieter Barnhoorn, Chris Walinga

Leiden University Medical Center, department of Public Health and Primary Care, Leiden, the Netherlands

BACKGROUND and AIM:

Until now, the aetiology of sleep-related painful erections (SRPEs) is unknown. There are various hypotheses about the pathophysiology. As a result different treatments have been proposed during the last four decades. However, not every patient with SRPEs agrees with pharmacological interventions for his SRPEs. We report a patient with SRPEs that only occurred after sexual intercourse in the evening.

METHOD:

A 40-year-old man presented with a 6 year history of SRPE always occurring after sexual intercourse with ejaculation in the evening. The patient underwent a bio- psychosocial evaluation by his general practitioner-sexologist as well as by a urologist-sexologist. Medical conditions, drug abuse, psychological and major relational issues were ruled out. The patient refused the proposed medication and shifted the time of sexual intercourse. After having sex in the morning or in the afternoon, he experienced no SRPEs anymore.

RESULTS:

Shifting the time of sexual intercourse to the morning or afternoon was effective in preventing SRPEs.

CONCLUSIONS:

Careful history taking is always important, especially with regard to symptoms that are only rarely reported in common practice. This case revealed that SRPEs may be related to intercourse in the evening before. Changing the time of sexual intercourse may be the simple solution.

Gingival hyperplasia secondary to drugs

Cátia Pereira Da Silva¹, Diana Vaz De Miranda², Maria Lurdes Rodrigues³, Rosa Couceiro¹

¹General Practice and Family Medicine, USF Aquae Flaviae, Chaves, Portugal

²General Practice and Family Medicine, USF São Nicolau, Guimarães, Portugal

³Neurology, Centro Hospitalar do Alto Ave, Guimarães, Portugal

Background and AIM:

The gingival hyperplasia secondary to drugs is an exaggerated response of the gingival tissue that appears after systemic use of some drugs, which can cause aesthetic, functional and physiological discomfort. The pathogenesis and prevalence behind this is unclear. The drugs most commonly associated with this condition are anticonvulsants, immunosuppressants, and calcium channel blockers. This paper aims to remind the importance of the General Practitioner's acknowledgment of this adverse reaction when prescribing prolonged systemic use of these drugs.

Methods and results (Case description):

We relate a case of female patient, 53 years old, with Epilepsy since the age of 10 and with nodular goiter. Treated with phenytoin and primidone for about 10 years, with symptomatic control. Referred to the Neurology Department for replacement therapy due to side effects of chronic medication. Standing out from the objective examination, a gingival hyperplasia of the upper dental arch. The patient reported that she had had the same changes in the lower dental arch lower, with the placement of dental implants. Phenytoin was suspended and replaced by eslicarbazepine acetate.

CONCLUSION:

Gingival hyperplasia can cause pain and difficulty during mastication, gingival bleeding and periodontal changes. The cosmetic damage may substantially affect the social and professional quality of life of the patient and should not be ignored. Phenytoin is a popular antiepileptic often associated with the development of this pathology. Despite the symptomatic disease control with phenytoin, the replacement therapy is mandatory, as it is a common side effect of antiepileptics. The therapeutic adjustment and reinforcement of appropriate orodental hygiene should be the first line of action.

Keywords: Gingival hyperplasia, phenytoin, anticonvulsants

Chronic Obstructive Pulmonary Disease and smokers working in highly polluted areas

Maria Chalkidou¹, Maria Bakola², Konstantina Mavridou², Efcharis Fileli¹

¹Primary health care center of Tsotyli, General Hospital of Kozani, Kozani, Greece

²General Hospital of Ioannina „G.Hatzikosta“, Ioannina, Greece

Background & AIM: Chronic Obstructive Pulmonary disease (COPD) is a leading cause of morbidity and mortality worldwide and results in an economic and social burden that is both substantial and increasing. Inhaled cigarette smoke and other noxious particles such as smoke from biomass fuels cause lung inflammation, asthma, lung cancer etc. The aim of the study was to evaluate smokers who work in unhealthy areas.

METHOD: 78 smokers, employees at the Hellenic Electricity Corporation, were evaluated at our primary care health centre, between November 2013 and June 2014. Data were collected by means of a modified questionnaire based on COPD Assessment Test, Modified Medical Research Council Dyspnea Scale and COPD population screener.

RESULTS: Study sample included 72 male and 6 female smoker employees, aged 30 to 59 years, divided in three age groups. Group I (30 to 39) n = 26; Group II (40 to 49) n = 33; and Group III (50 to 59) n = 19 The symptoms of COPD are evident in Group II. The number of daily cigarettes predominates in Group III which is the group that seems to have more symptoms. The average age of daily smoking initiation was 17.5 years old. The number of episodes of breathlessness, chest tightness, shortness of breath increases with age.

CONCLUSIONS: Often patients approach the doctor with delay and respiratory infections usually are not attributed to COPD. The average patient with COPD at diagnosis has already lost 50% of respiratory function. Family medicine physicians should always have in mind that smokers who work in an unhealthy environment are more likely to develop COPD symptoms. It is necessary to work on the prevention of smoking in such areas, recognize early symptoms of COPD and refer the patients to pulmonologists for further evaluation and treatment.

Acute superficial lymphangitis following a kitten bite. Cat scratch disease? A case report

Maria Bakola, Konstantina Mavridou, Eyfrosyni Gianouza, Akrivi Logotheti, Maria Chalkidou, Christodoulos Papaioannou

Primary care health center of Derviziana, General Hospital of Ioannina „G.Hatzikosta“, Ioannina, Greece

Background & AIM: Cat scratch disease (CSD) is caused by *Bartonella henselae*, a gram negative bacteria which is most often transmitted to humans through a bite or scratch from an infected cat or kitten. CSD often is a self-limiting condition but sometimes can affect major organ systems of the body. The aim of this case report was to draw the attention of family physicians concerning this disease.

METHOD: A 53-year-old man presented to the primary care health centre with rapidly progressive right arm pain and erythema.

The history revealed a kitten bite in his right thumb 36 hours ago. The patient had no symptoms until the next day when his thumb became increasingly painful, with erythema spreading to his wrist, which prompted him to seek medical care. On presentation, the temperature was 39,2 °C, the heart rate 61 beats per minute, and the blood pressure 121/79 mm Hg.

RESULTS: The physical examination revealed a painful pustule on his right thumb with surrounding warmth, tenderness, erythema, and linear streaking to the elbow as well as axillary, painful and ipsilateral lymphadenopathy. The patient was referred to the hospital where empirical antibiotic treatment with clindamycin was initiated. By the third day of hospitalization, the erythema and the pain had improved, and the patient was discharged after seven days, while receiving oral antibiotics for another 14 days. At follow-up two weeks after discharge, the pustule was crusted and the erythema was substantially improved.

CONCLUSION: Although *Bartonella henselae* was not confirmed in our case, it is important for family physicians to recognize patients at risk of CSD and have in mind that can develop systematic symptoms as well as lymphadenopathy. In such cases the patients should be referred to the hospital in order to receive intravenous antibiotic therapy.

Differences between primary care in developed and developing countries - From Portugal to a Burmese refugee-camp in Thailand, two different worlds

Pedro Caetano¹, Carolina Moreira²

¹USF Nova Via - CHVNG, Porto, Portugal

²CHP - Serviço de Fisiatria, Porto, Portugal

BACKGROUND

In the last years there was an increase in quality patient care in Portuguese health system, mainly because of an improvement in primary care quality due to creation of last generation health centers – Unidades de Saúde Familiar B (USF B). The health care provided in a refugee camp in an developing tropical country is totally different from the standards that we have in Europe. MaeLa refugee-camp provides shelter for ~45000 refugees. Inside the camp, a humanitarian organization provides free acute primary care in a outpatient department (OPD). Infectious diseases are a significant cause of morbidity and mortality in the developing world. Viruses contribute significantly to medical consultation, although data for low-income and tropical countries are scarce. The aim of this work was to compare the different motifs of acute primary care consultations between a developed country and among refugees living on the Thailand-Myanmar border.

METHODS

RESULTS: collected data from open consultations carried out by the author in USF-Nova Via between January/March 2015 and lived experience from the author in MaeLa Refugee-Camp Thai-Myanmar border in November/December 2014.

RESULTS

The most common motifs in USF-Nova Via`s acute consultations were: upper respiratory infections, administrative procedures, musculoskeletal diseases in comparison with motifs in MaeLa Refugee-camp in which infectious diseases prevailed with tropical diseases such as malaria, parasites, dengue, lower respiratory infections, measles and diarrhea on top.

CONCLUSION

There are meaningful gap in health care conditions between developed and developing countries. Developed countries have prevention standards, hygiene conditions and public health politics, as well as health education on the other hand, developing countries infectious diseases still have the higher impact, due to the lack of structural conditions and health education.

Individuals in conflict-affected areas rarely get appropriate care for chronic or non-infectious diseases, due to that, infections continue to be the most common motifs.

From Space to day to day - Medical Innovations

Pedro Caetano¹, Carolina Moreira²

¹USF Nova Via - CHVNG, Porto, Portugal

²CHP - Serviço de Fisiatria, Porto, Portugal

BACKGROUND and AIM:

Space investigation is in the center of many important medical and technological inventions.

Since the beginning of manned space flight that NASA's role in medical breakthroughs is unquestionable, with a crescent importance with the establishment of space agency.

The research led to the design of different protocols and medical devices that we use daily in our medical practice.

METHOD

Bibliography research, collected data and lived experience from the author's internship in aerospace medicine in NASA-UTMB.

RESULTS

Artificial members: NASA robotic department led to the discovery of very light materials, with great power to absorb the impact and that adjusts to human conditions, leading to the construction of new prosthesis

Ocular screening: An image-processing technique developed by NASA and now used to detect eye problems in very young children.

Insulin-Bomb: the need to have a permanent monitoring of astronauts health led to the development of vital control devices over long namely by controlling sugar level in the blood and inducing an adequate dose of insulin - now known as the insulin pump, helping control blood sugar in people with diabetes.

MRI and CT: Occasionally NASA didn't invent the breakthrough, but rather the technologies that led to breakthrough. NASA's Jet Propulsion Laboratory (JPL) developed digital image processing to enhance pictures of the moon, that contributed to MRIs and CT.

Headset Thermometer: Taking advantage of the technology that NASA uses to measure the temperature of stars, using infrared technology, was created an infrared sensor that is used as ear thermometer.

CONCLUSION

Remote health-monitoring sensors and insulin-bomb, that helped to make the control of the diabetes process easier to manage, are just two examples derived from orbital space medical programs. Our health, medical knowledge and capabilities have grown greatly because of space exploration and the equipment and techniques developed for it.

Alcoholic Cardiomyopathy

Özden GÖKDEMİR¹, Ülkü BULUT³, Kemal Aygün⁴, Hüseyin Dursun², Mehtap Kartal¹, Dayimi Kaya²

¹Dokuz Eylül University, Medical Faculty, Family Medicine Department, İzmir, Turkey

²Dokuz Eylül University, Medical Faculty, Cardiology Department, İzmir, Turkey

³Torbali Public Health Care Center, İzmir, Turkey

⁴Dokuz Eylül University, Medical Faculty, Internal Medicine Department, İzmir, Turkey

BACKGROUND: According to WHO approximately 2 billion people consume alcohol. It is stated that little/moderate consumption of alcohol reduces cardiovascular disease risk due to antioxidant, anti-inflammatory, even anti-coagulation effects. However its mostly known abuse outcomes are impairments in cognition, reflexes, judgments and movements as it effects neurological system.

CASE: A 47 year old male admitted to the emergency room with complaints of palpitation, dyspnea of New York Heart Association (NYHA) Class 3 which was started a month ago. His coronary angiography, performed a year ago due to nonspecific complaints, was normal. In his physical examination; 2/6 degree systolic heart murmur was audible on the mitral area. Electrocardiography showed an atrial fibrillation rhythm with a rate of 110/min without any ischemic signs. Global hypokinesis of left ventricle with an ejection fraction of 25% and moderate degree mitral insufficiency were detected on transthoracic echocardiography. In his medical history his alcohol consumption was more than three glass/day. He has been hospitalized as dilated cardiomyopathy, atrial fibrillation. Amiodarone of 1000 mg was started intravenously for cardioversion. However atrial fibrillation persisted, electrical cardioversion performed for sinus rhythm achievement. His control echocardiography under sinus rhythm was similar. He discharged as complaints declined. In his third month control he was asymptomatic, considered as NYHA stage 2. As he had no detectable ischemic pathology in coronary angiography, cardiomyopathy couldn't be due to ischemic etiology.

DISCUSSION: Physicians should keep in mind the alcoholic cardiomyopathy for their patients with signs of heart failure and should carefully evaluate the alcohol consumption. However besides the long term use of alcohol, the

possible asymptomatic course of the disease should not be forgotten. So high alcohol consuming patients should also be informed about alcoholic cardiomyopathy. More than 80 gr/day of alcohol consumption with a minimum of 5 years is considerable for diagnosis and treatment includes cessation of alcohol and standard treatment of heart failure.

Burn out among private general practitioners of the region of Sousse (Tunisia)

Meriam El Ghardallou¹, Thouraya Ajmi², Manel Limem¹, Awatef Jawadi¹, Menel Mellouli², Chekib Zedini¹, Iheb Bougmiza², Ali Mtiraoui¹

¹Department of family and community medicine, Faculty of medicine, University of Sousse, Tunisia

²Laboratory research of quality of maternal health care, "LR12ES03". Faculty of medicine of Sousse, Tunisia.

BACKGROUND:

In the last few years, pressure on Tunisian doctors has risen as a result of several changes such as economics constraints. This resulted in work stress and in increase of chronic reactions like the burn out syndrome.

AIM:

This study aimed to evaluate the prevalence of burnout among private general practitioners (GP) of the region of Sousse (Tunisia).

METHOD:

We conducted a descriptive cross sectional design evaluating the burnout syndrome among GP in the sanitary region of Sousse.

It was carried out in 59 GP working in the private sector of the primary health care during December 2014.

Data were collected via a structured questionnaire with two mainly parts:

The first concerned the socio-demographical variables (age, marital status, time when the installed their practice, type of practice...) the second corresponded to the French version of the Maslach Burn out Inventory (MBI). The data were analyzed using SPSS.18.

RESULTS:

The majority of participants were men (72.4%), living in an urban area (91.2%) and were married (86.2%). Their mean age was 47 years \pm 11.

Median scores on the three dimensions of burn out (emotional exhaustion, depersonalization, low personal accomplishment) were respectively 22.5 [Q1=13 - Q3= 27.2], 4 [Q1=1 - Q3= 8] and 43 [Q1=39 - Q3= 46].

About fourteen per cent of the practitioners had high scores of burn out on the 3 subscales.

CONCLUSION:

Burnout among doctors is becoming a serious problem that can affect patient care. However, it still be prevented.

Fatigue and excessive daytime sleepiness in patients with Myotonic dystrophy type 1

Ana Borivoje Bojčić¹, Veroslava R. Maksimović¹, Stojan Perić²

¹Health center Dr Simi Milosevic, Belgrade

²Institute of neurology, Clinical Centre of Serbia, School of Medicine, University of Belgrade, Serbia

OBJECTIVES: Myotonic dystrophy type 1 (DM1) is a multisystemic disorder. The main emphasis is usually placed on progressive muscle weakness and myotonia, while central nervous system manifestations have received little attention.

AIM: To evaluate the presence of fatigue and excessive daytime sleepiness (EDS) in patients with DM1 and to assess if these two symptoms affect quality of life (QoL).

Patients and METHODS: This study included 62 consecutive patients with adult form of DM1 who were seen at the outpatient unit of the Institute of Neurology, Clinical Center of Serbia. Severity of muscular involvement was measured by MRC score. Following assessment questionnaires were used: the Fatigue Severity Scale (FSS), the Daytime Sleepiness Scale (DSS), the Hamilton Depression Scale and the SF-36 questionnaire.

RESULTS: Our study showed that 58% of DM1 patients were fatigued and 40% were sleepy. Fatigue was related to the age of patients ($p < 0.05$), their muscle strength ($p < 0.01$) and the level of depressiveness ($p < 0.01$). However, EDS was related only to the level of depressiveness ($p < 0.01$). SF-36 total score was significantly affected by fatigue ($p < 0.01$), but not by EDS ($p > 0.05$).

CONCLUSION: Significant fatigue was observed in majority of DM1 patients and it significantly affected their health-related QoL. EDS was frequently found in DM1 patients and it may present a danger to the patients themselves and to the others.. We emphasize the importance of development of compensatory strategies to reduce fatigue and EDS in patients with DM1.

Keywords: myotonic dystrophy, fatigue, excessive daytime sleepiness

Diagnosis indurated leg injury

Lorea De Unamuno Lumbreras¹, Verónica Parent Mathias², Irina Yezerska Sushko³, Juan Manuel García López²

¹El Palo Primary Health Center, Málaga, Spain

²Department of Emergency of Regional Hospital, Málaga, Spain

³Cantabria Public Health Service, Spain

Medical history: former smoker, tonsillectomy 12 years ago, at age 9 hospitalization for nodal tuberculosis. He does not take medication.

Anamnesis: male patient aged 37 who consults for several days about indurated lesions on the front of both legs somewhat painful to touch.

He denies fever or sweating. No cough or diarrhea or joint pain. No prior throat infection.

Exploration: On the front of both legs several painful erythematous nodules are seen to touch resizable between 2 and 6 cm in diameter.

Additional tests: Blood test: blood count, hemostasis and normal biochemistry, ASLO negative, HIV, HBV, CMV, EBV negative syphilis and toxoplasmosis. Chest radiography revealed nothing abnormal. Skin test negative tuberculin.

Clinical Trial: Erythema nodosum (EN) idiopathic.

Differential Diagnosis: The EN can be confused with other forms of panniculitis, especially nodular vasculitis, the Weber-Christian disease, subcutaneous bacterial or fungal infections, superficial thrombophlebitis and cutaneous vasculitis.

Treatment: Erythema nodosum is usually a benign condition and self-limiting to cure without sequelae, but sometimes painful, so treatment should be aimed at improving the symptoms with rest and anti-inflammatory drugs and treat the underlying cause if any.

Evolution: The lesions healed without scarring in two months.

CONCLUSIONS: The interest of erythema nodosum is not only in making a diagnosis of the skin lesion, but in examining the possible existence of an underlying disease associated. In the case described highlights the history of tbc in childhood, although their association is discarded. The list of possible etiologies is extensive: infectious cause: hemolytic streptococcus, tuberculosis, yersinia, salmonella, campylobacter, HIV, HBV, CMV, EBV, syphilis, toxoplasmosis; sarcoidosis; inflammatory bowel disease; Behcet disease; connective tissue diseases; lymphomas; carcinomas; drugs such as oral contraceptives, analgesics, penicillin.

EN idiopathic is a diagnosis of exclusion, however, the clinical monitoring should continue over time to rule the late appearance of some pathology as erythema nodosum may precede these entities from months to years.

The stigmatization of tuberculosis patients registered at Maltepe and Bahcelievler tuberculosis dispensaries in the province of Istanbul

Seyhan Hidirođlu¹, Abdullah Sariöz¹, Mahmoud Bhais¹, Seda Karakurt¹, Hasan Can Şahan², Melda Karavuş¹

¹Department of Public Health, Marmara University, Istanbul, Turkey

²Maltepe tuberculosis dispensaries, Health ministry, Istanbul, Turkey

Introduction

This research has been conducted to determine the status of the stigmatization of tuberculosis patients registered at the tuberculosis dispensaries in İstanbul. Stigmatization results in preconception which in turn leads to discrimination. Discrimination as a result of preconception and stigmatization leads to loss of rights and benefits

These social concepts lead to huge imposition on the patient. This situation places a huge strain on the patients and affects the treatment adversely.

METHOD:

Stigma Scale for Patients with Tuberculosis is used. The Cronbach's alpha coefficient has been found as 0.91. The scale is composed of four sub-dimensions: "Felt stigma, Self-perception, family-friend relationship, internalized stigma".

Without any specific sample selection our research population consisted of active tuberculosis patients and patients who have been completing the treatment in Maltepe and Bahcelievler districts of İstanbul. Study is conducted between 15 of January 2015 to 15 of February 2015. The data have been collected from 186 patients.

The patients, who came to the dispensaries between the dates specified, were included in the research and some of them were reached by phone call. Non-parametric tests such as Mann-Whitney U and Kruskal Wallis were used because parametric conditions were not provided. Statistical significance is accepted as $p < 0.05$

Results

In the study, there was no significant difference for age, sex, education, marital status, and living area variables. For total scale score, patients with complicated treatment condition, patients with pulmonary tuberculosis, patients with low socio-economic status, patients working as employee worker and patients who have not have any tuberculosis relatives at their houses or family environment within the last year have higher median stigma scores which were statistically significant.

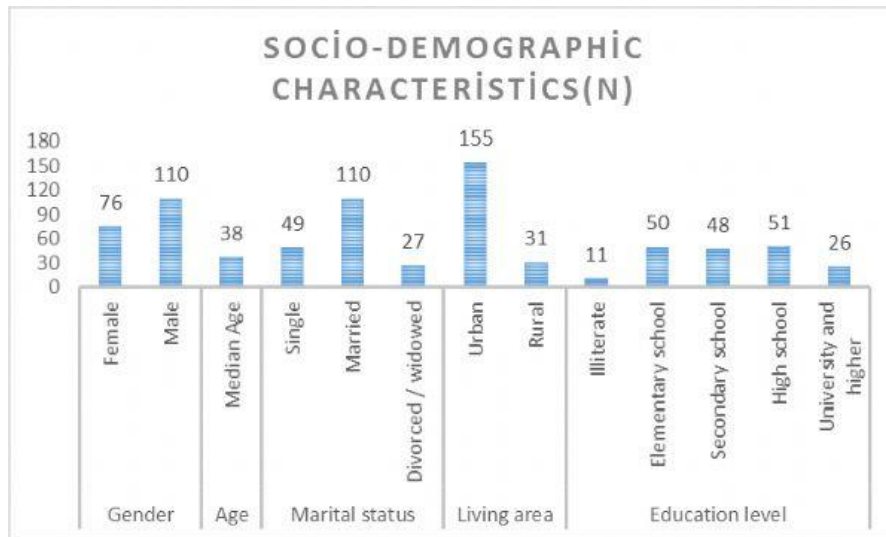

In sub-scales same significant results were also achieved.

Conclusions

Level of stigma was found higher in patients with complicated treatment condition, pulmonary tuberculosis, low socio-economic status, and working as employee.

Keywords: Mycobacterium tuberculosis, Social Stigma, Istanbul

Socio-demographic characteristics of the participants

"Listening to right hemisphere in primary care consultation"

Silvia Membrilla Pastor

CAP RAMONA VIA. EL PRAT DE LLOBREGAT

BACKGROUND

Interest for the life of the emotions, a land where they have not been educated in general and when difficult situations leads to a difficult management arise.

This led me to take courses for personal growth.

Once the Master of Leadership and personal development ask me to do a presentation where I explain so that has helped me and as I have been able to apply in my work.

TARGET

Capture in my practice my knowledge about the importance of emotions and the right hemisphere in our lives

METHOD

We selected a group of patients who had consulted by physical or emotional problems revealed great emotional distress.

Were treated with standard tools I usually use in the query.

A posteriori test I passed them on as obtained before and after care.

Emotion recognition, prioritization guidelines, enhancing sports and activities contact with the inner Self.

There was a free hand to express creatively their current state, most had already surpassed the state of emotional blockage.

RESULTS

A clear subjective and objective improvement attending to their literal responses and emotions described in the current state. They added pictures, music and inspiring positivity situations.

CONCLUSIONS

A holistic consultation with enough time to explore emotions, to discriminate the physical symptoms that are not organic and provide space support an improvement in the quality of life of patients, and often avoids situations medicalization of emotional disorder (symptomatic treatments explorations... etc). The sensitization of primary care professional in these serious issues essential to achieve this.

Prevalence of thyroid cancer in patients referred from primary care to a high-resolution thyroid nodule clinic

Carmen Maria Cortes Salazar¹, Jose Carlos Fernández Garcia², Diana Domínguez Jiménez³, Isabel Mancha Doblas²

¹Primary Care Centre of Badolatosa, Seville, Spain.

²Endocrinology Department, Virgen de la Victoria University Hospital, Málaga, Spain.

³Primary Care Centre of Estepa, Seville, Spain.

BACKGROUND & AIM: Thyroid cancer is the most common endocrine malignancy. In this study we aimed to evaluate the prevalence of thyroid cancer in patients with suspected thyroid nodule referred from primary care to a high-resolution thyroid clinic.

METHOD: Retrospective cohort study which included patients with suspected thyroid nodule referred from primary care to a high-resolution thyroid nodule clinic. Demographic and clinical characteristics were collected, all patients underwent thyroid ultrasound and subsequently, a fine needle aspiration (FNA) was performed if thyroid nodules were >1cm of diameter or if there was evidence of risk factors for thyroid carcinoma (in accordance with American Thyroid Association guidelines).

RESULTS: 987 patients were included in this study. After performing thyroid ultrasound the presence of a thyroid nodule was detected in 79.5% of patients (785 nodules) with a mean nodule diameter of 2±1.15 cm. FNA was performed in 585 nodules (74.5% of all nodules). 11.8% of all cytological samples had suspected malignancy and 2.1% were malignant. Referral for surgery was required in 23.2% of patients (mainly because of nodule size or suspected malignancy). Malignancy was confirmed in 5.6% of thyroid nodules.

CONCLUSIONS: The prevalence of thyroid cancer in this cohort of patients from primary care is 5.6%. Thus, approximately 1 out of 20 thyroid nodules referred from primary care to a high-resolution thyroid clinic is malignant.

UPI's contributions to the education of health students at the Federal University of Vale do São Francisco Foundation in Brazil

Carla Santos Araújo¹, Ana Dulce Batista Santos², Karoline Barros Conceição², Láyla Moanna Araujo Moraes¹, Rafael Nascimento Barreiros³, Rafael De Abreu Maynard¹

¹Department of Medicine, Federal University of Vale do São Francisco Foundation, Petrolina, Brazil

²Department of Nursing, Federal University of Vale do São Francisco Foundation, Petrolina, Brazil

³Circo da Trindade Eventos e Produções LTDA, Olinda, Brazil

Background and Aim

Since Brazilian Unified Health System (SUS) undertakes health as a state duty, it supports its actions in the wider definition of health. Within this new conception, it's necessary to insert SUS principles - completeness, fairness and universality - in daily work. This new model bases the training of health professional on humanizing principles, taking a holistic approach to the needs of users as human beings, beyond the disease.

Thus, extension projects arise within universities, such as the Intensive Clownery Unity (UPI), created in 2011, a clowntherapy student project which aims to promote patient's well-being and to reduce tensions in work environment, enabling SUS experience on a non hospital-centered model.

It is the aim of this paper to report the experience of health courses students on how the UPI contributes to their professional training process. We declare that we have no competing interests related to this presentation.

Method

Reports of 25 undergraduate volunteers about their experience in health care, about what was learned in UPI and their professional education in health.

Results

Participation in the UPI allows students to work their sensitivity and subjectivity, using art as a guide to the reaffirmation of this new health care model, to understand the health practices in a wider way, respecting the complexity of human beings. It leads to the recognition of the project contribution to the formation of the professional profile required by SUS principles UPI also develops in its members a more sensitive vision about interpersonal relationships; promotes integration between the various health courses, respect for knowledge, multidisciplinary integration and teamwork, as recommended by the SUS.

Conclusions

The participation of students in UPI contributes to the formation process of future professionals in accordance with SUS principles and improves the relationships of all involved.

Can we trust the results of the urine dipstick for the identification of pyocytes and red cells? Comparison with microscopy

Konstantinia Karakoula, Zoi Tsimtsiou, Antigoni Tsimtsiliakou, Antonis Asimakopoulos, Elpida Efthimiadou, Eirini Litra, Achileas Koureas, Fotini Dantsi

Urban Health Center of Evosmos, Thessaloniki, Greece

Background & AIM: Urine dipstick testing is widely used in Primary Health Care settings. This study aimed in evaluating the sensitivity, specificity, positive and negative predictive values of the examination with dipsticks in identifying pyocytes and red cells in urine.

METHOD: All the results of the urine examinations that took place in the Primary Health Center of Evosmos from January to December 2014 were recorded, along with the gender of the examined patients. The results of the urine dipstick tests were compared with the findings of microscopy of the same urine sediments.

RESULTS: 1716 urine samples were examined. 135 (7.9%) were positive for the pyocytes (enzyme of the leukocyte esterase) and 739 (43.1%) for red cells (method of peroxidase activity of erythrocytes). The sensitivity of the urine dipstick test for the detection of pyocytes (≥ 4 per field) was 28.2%, the specificity 99.6%, the positive predictive value 96.3% and the negative predictive value 79.1%, whereas for the detection of ≥ 12 pyocytes per field the results were respectively 45.7%, 84.8%, 78.5% and 92%. The corresponding values for the detection of hematuria (≥ 3 red cells per field) were 92.6%, 99.5%, 98.6% and 97.4%. When the dipstick found one plus (+) for pyocytes the median value of the pyocytes counted with microscopy was 18 to 20 per field, in two plus (2+) 50 to 60 per field and in three plus (3+) 53 to 60 per field.

CONCLUSIONS: Urine dipstick testing can serve as a useful guide to the physician of Primary Health Care settings, as a screening test or as a diagnostic test, but there are many times that the dipstick results have be correlated with microscopy and clinical parameters, especially for the detection of urinary tract infections.

How "Tweetchats" can be used as a tool to develop online communities and engagement: The #FMChangeMakers Experience

Claire Marie Thomas, [Patrick Reichel](#), Hassna Errami, Harris Lygidakis

#FMChangeMakers, Vasco de Gama Movement

Background/Aims

#FMChangeMakers is an initiative born out of a working group at the Vasco de Gama Movement Preconference of WONCA Europe Conference 2014. Initially, known as #VdGMChangeMakers, the group was formed to develop tools and resources to aid young GPs interested in initiating changes in their local and national health and education systems. The primary communication platform for the group has been social media, most notably our regular tweetchats, and subsequently the #FMChangeMakers movement has been born.

Our aim is to analyse the contribution of tweetchats to the evolution of the #fmchangemakers network to determine the value of further investment in developing the culture of tweetchats, as well as provide possible lessons for other evolving online communities.

Method

We have utilised statistics generated by the Symplur healthcare hashtags project to analyse the reach and impact of the FMChangeMakers hashtag. Cumulative data on impressions, participants and mentions has been evaluated over time and cross-referenced with the dates of tweetchats and other key events.

Results

Each successive tweetchat has directly led to growth in impressions (1,575,485), mentions (1,647) and participants (113). Tweetchats have also contributed to the rapid expansion of our network beyond Europe. There is a variance in the impact of the tweetchats, which is related to the publicity and advertising of each chat. The majority of the tweetchats led to more growth than face-to-face events such as the VdGM Forum.

Conclusions

Tweetchats can be an effective and innovative way to engage, develop and grow an international online community. Their impact is maximised through regular and consistent publicity and advertising and a robust facilitative process. Most notably they present opportunities for expanding dialogue and networks, both globally,

inter-professionally and across the patient/professional divide. Tweetchats are a potentially invaluable tool for advocacy, knowledge sharing and the future development of global family medicine.

Cerebral stroke during pregnancy

Alexandru Claudiu Coman, Madalina Daniela Graure, Juana Flores Torrecillas, Florentina Guillen Cavas, Enrique Pagan Dato, Rosa Requena Ferrer
Cartagena Casco Health Center, Cartagena, Spain

Background & Aim

A 30 years-old woman, 6 weeks pregnant, refers a short episode of paresthesia and loss of strength in her upper left arm the day before consulting her General Practitioner. Four days later a similar episode occurs. The first neurological exploration is normal. After the second episode, she presents a slight dysarthria with left central facial palsy and distal weakness mainly at wrist extension. No sensitive alterations. She is remitted to the Emergency room suspecting a stroke.

Method

Complementary tests: Blood analysis is normal. Magnetic nuclear resonance imaging: Acute right basal ganglia stroke. Neurosonology study, Echocardiography, Venous ultrasound, thrombophilia study are negative.

Results

Diagnosis: Acute right basal ganglia stroke

Differential diagnosis: Intracerebral tumor, Intracerebral hemorrhage

Evolution

The patient is admitted to the Neurology Department. Treatment with antiplatelet drugs is installed, with continuous improvement in patient status. Within 24 hours of hospitalization the patient was not presenting neurologic symptomatology.

On the 39th week of pregnancy cesarea section is performed. The patient continues to be asymptomatic.

Conclusions

During pregnancy due to the hormonal changes there is a procoagulant state which increases the risk of venous thrombosis and potential stroke. Ischemic and hemorrhagic events in pregnant women could be due to the increase of risk factors like obesity, diabetes or hypertension.

The general practitioner must prevent the instauration of this risk factors in pregnant women or, if they are already installed, to maintain a close and thorough follow up of these women.

Keywords: pregnancy, paresthesia, stroke

Background & Aim

A 63 year-old woman attends her general practitioner for polymyalgia with low fever and asthenia in the last week. Medical history: Smoker. COPD. Hypothyroidism. Right pneumonia in 2009. Hypopharyngeal carcinoma in 2003.

The clinical examination shows diminished vesicular lung sounds and digital clubbing.

Method

Complementary tests:

Blood analysis: Complete blood count was normal. Biochemical: PCR 3.9, VSG 43, TSH 5.38, T4 0.99 Rheumatoid factor 11, Tumor marker: CEA 8.2.

Thoracic radiography: left pulmonary mass

Thoracic CT-scan: 4.8 cm pulmonary mass in the lingula area of the left lung

PET-CT-scan: malignant lung tumor (lingula)

Bone scintigraphy: the right sacrum presents an area of hypercaptation suggesting bone metastasis.

Pneumology Department: the treatment with bronchodilators is increased and the patient is remitted to the Thoracic Surgery Department.

Rheumatology Department: treatment with corticosteroids and analgesics is initiated.

Results

Diagnosis: Lung adenocarcinoma T2a-3N1M1

Differential diagnosis: Pulmonary or digestive neoplasms, Cardiomyopathy

Conclusions

Digital clubbing is a sign caused by a deformity of the fingers and fingernails. It can be an isolated event or part of the hypertrophic osteoarthropathy syndrome. It is associated with neoplasms, mostly intrathoracic, digestive system and cardiovascular diseases. Once detected, the general practitioner should perform a complete physical examination and if necessary, complementary tests considering the severe pathologies that might involve.

Keywords: hypertrophic osteoarthropathy, neoplasm metastasis, lung neoplasm

Aspirin in the prevention of recurrent pregnancy loss: what is the evidence?

Susana Sá¹, Joana Castanheira², Margarida Gameiro³

¹Unidade de Saúde Familiar Sem Fronteiras, Agrupamento de Centros de Saúde Entre o Douro e Vouga I, Portugal

²Unidade de Saúde Familiar Fiães, Agrupamento de Centros de Saúde Entre o Douro e Vouga I, Portugal

³Centro Hospitalar Entre o Douro e Vouga, Serviço de Ginecologia e Obstetrícia, Portugal

INTRODUCTION: Recurrent pregnancy loss (RPL) classically refers to the occurrence of three or more consecutive losses of clinically recognized pregnancies prior to the 22th week of gestation. The etiological investigation is important, but it is conclusive in about 50% of couples. An increased production of thromboxane A2 and decreased production of prostacyclin were verified in RPL, which may be the mechanism involved. Aspirin in low doses inhibits the synthesis of thromboxane A2, while preserving vasodilation and antiplatelet effect of prostacyclin.

OBJECTIVES: To determine if there is evidence for the use of aspirin in preventing RPL, compared with other treatments or placebo.

METHODOLOGY: It was made a research in Evidence Based Medicine Databases of articles published between January of 2004 and October of 2014, written in English and Portuguese. The Mesh terms were: "Recurrent miscarriage" AND "Aspirin". We used the Strength-of-Recommendation Taxonomy (SORT) of American Family Physician to established the levels of evidence and recommendation forces.

RESULTS: We identified 52 articles and, of these, selected 9 that met our inclusion criteria: 3 consensus guidelines (CGs), 2 meta-analysis (MA), 3 randomized controlled trials (RCTs) and one cohort study (CS). CGs recommended antithrombotic prophylaxis only in case of Antiphospholipid Syndrome (APS). Just a MA showed some evidence of combination therapy (heparin plus aspirin) in reducing abortions in women with APS and RPL, although not very consistent. The RCTs showed contradictory results. The CS concluded that antithrombotic prophylaxis should only be recommended in APS and RPL.

DISCUSSION: Accordingly to the available scientific evidence, the antithrombotic prophylaxis is not recommended in women with RPL and no history of APS/ Thrombophilias (SORT A). It can be considered, in women with APS and RPL, heparin in prophylactic dose and low-dose aspirin (SORT B).

Keywords: Recurrent pregnancy loss, Aspirin, Antiphospholipid Syndrome

RESULTS

CG	Recommendation	RF
1	Antithrombotic prophylaxis is not recommended in women with ≥ 2 miscarriages and no history of APS/ Thrombophilias	IB
2	Women with unexplained RPL have an excellent prognosis without pharmacological intervention; In APS: consider treatment with low dose aspirin + heparin	B
3	APS: consider treatment with heparin in prophylactic dose with or without low-dose aspirin	B
3	Antithrombotic prophylaxis is not recommended in the absence of APS	A

CS	Population	Intervention	Outcomes	EL
4	Liverpool; n = 636; 1986-2006 ≥ 2 miscarriages before 24 weeks of gestational age (unexplained/ + antiphospholipid antibodies [APA])	Unexplained miscarriage: ASA (n=146) VS ASA + LMWH (n=36) VS Untreated (n=294) Positive APA: ASA (n=98) VS ASA + LMWH (n=62)	Unexplained miscarriage: No significant differences between interventions + APA: Fewer abortions in the 1 st trimester with combined therapy [OR=0.4, CI 95% 0.2-0.7]	2

MA	Description	Intervention and Outcomes	EL
8	8 CRCTs ≥ 2 miscarriages before 24 weeks of gestational age, with or without hereditary thrombophilia	No evidence to support anticoagulation in preventing RPL in women with or without thrombophilia ASA vs Placebo / ASA vs LMWH + ASA / ASA vs ASA + LMWH vs Placebo → No significant difference in the number of live births among groups ASA vs LMWH → The number of live births with LMWH significantly increased only in the subgroup of women with primary recurrent abortion (RR=1.24; CI 95% 1.02-1.49)	1

CRCT	Population	Intervention	Outcomes	EL
6	Libyan; n = 150; Jan/2009 to Dec/2010 ≥ 2 consecutive miscarriages	ASA 75 mg/day (n=75) VS Enoxaparin (0.4mL/day) + ASA (75 mg/day) (n=75)	• Limitations: Unblinded; Without exclusion of thrombophilias/ APS/ endocrine factors; Small sample size • Strong points: Appropriate allocation; No follow-up losses; No statistically significant differences between groups Fewer miscarriages with the combination therapy (29% vs 47%, p < 0.001)	2
7	Iraq; n = 141; Sept/2007 to Aug/2010 ≥ 2 miscarriages before 20 weeks due to APS	Aspirin 100 mg/day (n=61) VS Bemiparin 2500IU/ 0.2mL/day (n=80)	• Limitations: Unblinded; Unclear allocation criteria; Without exclusion of thrombophilias; Small sample size. • Strong points: No follow-up losses; No statistically significant differences between groups Fewer miscarriages with bemiparin (86.25% vs 72.13%; p=0.045; CI 95% 0.08-0.274)	2
8	Netherlands; n = 364; Feb/2004 to Jan/2008 ≥ 2 miscarriages before 20 weeks, unexplained	ASA (80 mg/day) + Nadroparin (2850IU/day) (n=123) VS ASA (80 mg/day) + Placebo (n=123)	• Strong points: Multicenter study/ Sample size/ Appropriate allocation; Well-defined criteria for inclusion/ exclusion; Well-defined outcomes; Evaluation and inclusion of inherited thrombophilias; Double-blind; Intention-to-treat analyses; No statistically significant differences between groups (excluding alcohol, > placebo) No statistically significant differences between the groups regarding the number of live births/ miscarriages, both in the presence and absence of hereditary thrombophilia	1

MA	Description	Intervention and Outcomes	EL
6	6 CRCTs ≥ 2 miscarriages with positive anticardiolipin and lupus anticoagulant	• Unfractionated heparin (UFH) twice day + low-dose ASA appears to be effective in reducing abortions in women with positive APA and RPL without other causes identified • Further studies are needed to prove efficacy of LMWH ASA vs UFH + ASA → Significant reduction in the number of abortions with combination therapy ASA vs LMWH + ASA/ ASA vs Placebo / ASA vs Prednisolone + ASA: No significant differences in the number of abortions among groups.	2

Unknown thyroid dysfunction in patients with thyroid nodule

Carmen Maria Cortes Salazar¹, Jose Carlos Fernández Garcia², Diana Domínguez Jiménez³, Isabel Mancha Doblaz²

¹Primary Care Centre of Badolatosa, Seville, Spain.

²Endocrinology Department, Virgen de la Victoria University Hospital, Málaga, Spain.

³Primary Care Centre of Estepa, Seville, Spain.

BACKGROUND & AIM: To evaluate the prevalence of unknown thyroid dysfunction in a cohort of patients with thyroid nodule from primary care.

METHOD: Retrospective cohort study including patients from primary care referred to a high-resolution thyroid clinic. All patients had and ultrasound diagnosis of thyroid nodule. Demographic and clinical characteristics were assessed, and a thyroid blood test was performed (thyroid-stimulating hormone [TSH] and free T4 [fT4]). Patients under treatment con L-Thyroxine or antithyroid drugs were excluded from analysis.

RESULTS: 785 patients were included in the analysis (mean age 48.3±14,3years, women 90.8%). 38.4% out of patients had family history of thyroid disease. 6.7% out of patients had hypothyroidism (5.9% subclinical hypothyroidism) and 0.9% had hyperthyroidism (0.7% subclinical hyperthyroidism).

CONCLUSIONS: In this cohort of patients with thyroid nodule from primary care the prevalence of thyroid dysfunction is elevated. This finding indicates that the determination of thyroid function in patients with thyroid nodule is highly advisable.

Keywords: thyroid dysfunction, thyroid nodule, TSH

Don't hesitate to consult

Alexandru Claudiu Coman, Madalina Daniela Graure, Juana Flores Torrecillas, Florentina Guillen Cavas, Enrique Pagan Dato, Rosa Requena Ferrer, Encarnacion Esparza Perez
Cartagena Casco Health Center, Cartagena, Spain

• Background & Aim

A 55 year-old woman consults her general practitioner after noticing a nodule in the region of the neck around 2 months ago. She doesn't refer difficulty while swallowing.

Medical history: No smoker. Dyslipidemia. Menopause at 53 years. Amygdalectomy.

Clinical examination: Right thyroid lobe increased in size, with a nodule of around 1 cm.

• Method

Blood analysis: Cholesterol 272 mg/dl, Cholesterol HDL 88 mg/dl, Cholesterol LDL 172 mg/dl, Triglycerides 59 mg/dl y TSH 4.42 mIU/L, Antithyroglobulin antibody <244, Anti-thyroid peroxidase antibodies negative

Neck ultrasound: Enlarged right thyroid lobe that presents various nodules, the largest around 1.5 cm and two right lateral cervical lymphadenopathies (0.7 and 0.9 cm).

Fine-needle aspiration biopsy: papillary thyroid carcinoma with ganglion metastasis.

Surgery department: total thyroidectomy with extirpation of the lymphatic ganglions of the region.

After the surgery, an ablation with I-131 is performed and treatment with Levothyroxine 100 mg/daily is initiated.

• Results

Diagnosis: Papillary thyroid carcinoma pT3pN1b

Differential diagnosis: Goiter, Thyroiditis, Lymphoma, Carcinoma

• Conclusions

Thyroid cancer represents the most frequent malignant pathology between the tumors of the endocrine system. It is more frequent in women, around 30-50 year-old. Has a slow developing, with the tendency to metastasize in the cervical lymph nodules, although sometimes affects pulmonary or bone tissues. Prognostic is good, with a survival rate of more than 90% in a 20 years range.

Physical Therapy for Bell's Palsy: effective or unnecessary health care costs?

Susana Sá, Susana Rios, Miquelina Redondo

Unidade de Saúde Familiar Sem Fronteiras, Agrupamento de Centros de Saúde Entre o Douro e Vouga I, Portugal

INTRODUCTION: Idiopathic facial paralysis, also called Bell's Palsy (BP), can dramatically change the life's quality of a person, affecting the eyes, facial expression, speech, chewing and swallowing. Physiotherapy is commonly used in the treatment of BP, with significant associated costs and unclear clinical outcomes.

OBJECTIVES: To determine if there is evidence on the effectiveness of physiotherapy in comparison to other treatments or expectant attitude for the improvement of the signs and symptoms associated with BP.

METHODOLOGY: It was made a research in Evidence Based Medicine Databases of articles published between January of 2004 and March of 2014, written in English, Spanish and Portuguese. The Mesh terms were: "Bell Palsy" AND "Physical and Rehabilitation Medicine". We used the Strength-of-Recommendation Taxonomy (SORT) of American Family Physician to established the levels of evidence (LE) and recommendation forces.

RESULTS: Of the 26 articles found, only 2 randomized controlled trials (RCTs) and one systematic review (SR) respected the established inclusion criteria. The RCTs compares treatment with prednisolone and antiviral drugs (acyclovir or valacyclovir) with or without physiotherapy. Taking into account certain criteria (severity of BP, timing of physiotherapy...), the groups who underwent physiotherapy had better and/or faster clinical recovery (LE 2). The SR includes 12 RCTs, of which only 4 fit the established inclusion criteria. It concludes that, although it seems to exist a more rapid clinical improvement associated with physiotherapy in some studies, the poor methodological quality and the inconsistency of the results can't support the use of physiotherapy in BP (LE 2).

DISCUSSION: There isn't consistent evidence that treatment with Physical Medicine and Rehabilitation is more effective when compared to other treatments or expectant attitude in Bell's Palsy (SORT B). The authors conclude that further studies are needed with rigorous methodologies to obtain more consistent data.

Keywords: Bell's Palsy, Idiopathic facial paralysis, Physical and Rehabilitation Medicine

RESULTS

Reference	Studies	Intervention	Studies description	Results	EL
Systematic Review Teixeira J et al 2010	12 RCTs (only 4 meet the inclusion criteria)	<ul style="list-style-type: none"> Exercises (mime therapy) Electrotherapy / infrared treatment Without treatment Pharmacologic treatment 	Beerskens 2005 •BP - House-Brackmann (HB) IV for at least 9 months •Blinding of assessors •Inadequate allocation •Follow up: 3 months •N=34 •Age=44±14 years-old •Mime therapy vs without treatment	The poor quality of the RCTs and the inconsistency of the results obtained do not support the conclusion that there is significant benefit of physical rehabilitation in Bell 's Palsy	2

Hidden Causes of Erythema Nodosum

Irene Pérez González¹, María Carmen Fernández Alonso², Sara Nieto Sánchez¹, Aventina De La Cal De La Fuente¹, Claudia Bujedo Ortiz¹, Eva Sierra Quintana¹, Susana Sánchez Ramón³, André Duque Chaux³, Sandra Casado De Andrés¹, Yolanda Silva González⁴, Miriam Martínez Fernández⁵

¹Centro de Salud Casa del Barco, Valladolid Oeste, España

²Gerencia Regional de Salud, Valladolid, España

³Servicio de Urgencias, Hospital Universitario Rio Hortega, Valladolid Oeste, España

⁴Centro de Salud Plaza del Ejército, Valladolid Oeste, España

⁵Centro de Salud José Aguado, León, España

BACKGROUND & AIM:

24 year-old-woman referred history of 6 months of evolution of red nodule in right pretibial location, and recent appearance of left supraclavicular adenopathy. She didn't recount fever or polyarthralgia.

Primary care physician requested blood test and thorax X ray, revealing widened mediastinum and elevated acute phase reactants.

She was admitted to Hematology, for further mediastinum mass study.

METHOD:

-Physical examination: Normal vital signs. Cardiopulmonary auscultation: Regular without audible murmurs; preserved vesicular murmur. Abdomen: depressible, painless, not masses. Left isolated supraclavicular adenopathy. Erythematous plaque on right pretibial surface, without ulceration.

-Blood test: leukocytes 9500/mm³ (81%N;18%); LDH311; PCR30; VSG420; ANA,ECA,ANCA,proteinogram,serology (VIH,VHC,VHB,VHS,VEB,CMV,rubella,toxoplasma,syphilis): negative.

-ThoraxXRy: Widened mediastinum, pulmonary parenchyma not affected.

-Cervico-Thoraco-Abdomino-Pelvic Scanner: Anterior mediastinal mass (5x5cm) suggesting lymphoma.

-Skin Biopsy: Panniculitis involving septa compatible with erythema nodosum (EN).

-Thoracic Adenopathy Biopsy by Mediastinoscopy: Nodular Sclerosis Hodgkin Lymphoma.

RESULTS:

EN related to Nodular Sclerosis Hodgkin Lymphoma.

She received chemotherapy, with complete remission, and has attended to Hematology reviews for 5 years.

She contacted GP doctor 5 weeks ago because of right pretibial plaque, similar to previous EN, and was sent to Hematology. Several studies have been carried out to rule out different causes of EN, being attributed to pregnancy (gave birth 1 month ago).

CONCLUSIONS:

EN is characterized by red-violet subcutaneous nodules usually developed in pretibial location of women between 15 and 40. EN presumably represents delayed hypersensitivity reaction to antigens associated with infectious agents, drugs, diseases... although pathogenesis is unclear. It's important for primary care physicians to be alert of situations associated with EN (streptococcal pharyngitis, sarcoidosis, tuberculosis, histoplasmosis, Hodgkin Lymphoma, inflammatory bowel and connective tissue diseases, Behcet's and Whipple's diseases, gastroenteritis, pancreatitis, pregnancy, contraceptives, medications, SLE, HIV, syphilis, idiopathic...). Testing recommended to establish presence of associated diseases: blood test, liver enzyme, bilirubin, Antistreptolysin-O titer, serum creatinine and urea, plain chest radiograph, skin testing for tuberculosis.

Identifying information needs of people with rare diseases

Svenja Schürerer, Martin Frank, J. Matthias Graf Von Der Schulenburg

Center for Health Economics Research Hannover (CHERH), Institute for Risk and Insurance, Leibniz University Hanover

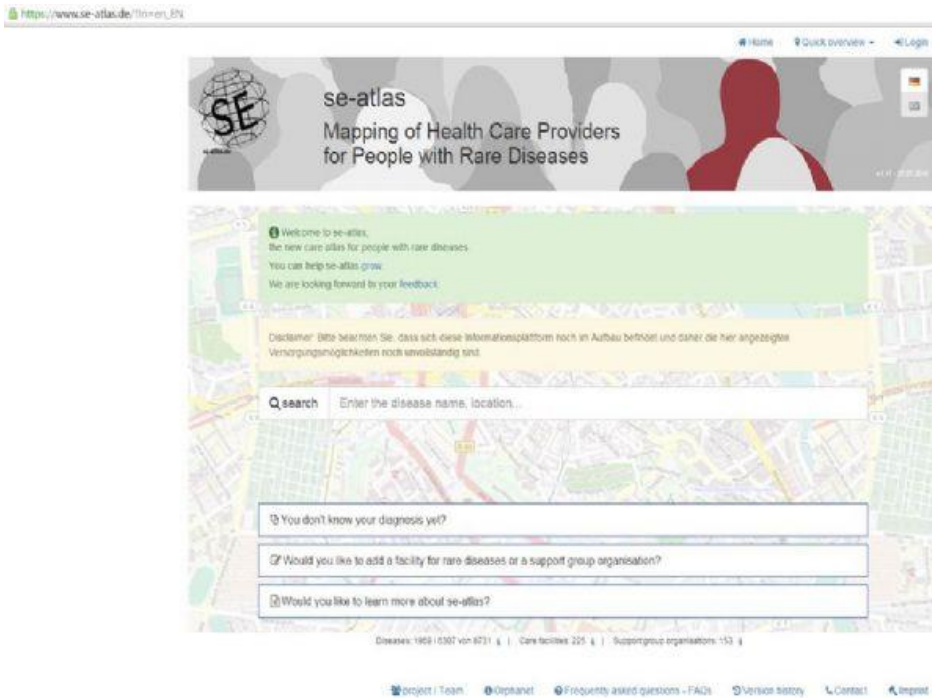

BACKGROUND & AIM: About 4 million people with rare diseases live in Germany. In 2013 a “National Action Plan” to improve patients’ health situation was adopted by the federal government. Establishing information systems is just one component of a broader set of measures to achieve this goal. Because family practitioners are often the first point of contact in patients’ health care, they are of great importance regarding their information needs. Therefore, the object of this study was to identify information needs of people with rare diseases and explore what role general practitioners play in information provision.

METHOD: A guideline for structured questioning was developed in order to detect patients’ experiences regarding diagnosis paths, information needs and information acquisition. Patients from eleven different groups of indications were taken into consideration. The evaluation followed the structured content analysis according to Mayring.

RESULTS: Interviews were conducted with 68 patients and family members. Several information needs could be derived from the interviews. Among other things, these include disease-related topics, regulations in health legislation as well as issues regarding daily life problems. For example, for some people therapeutic treatment options and details concerning disease progression are of potential interest. Moreover, respondents reported that general practitioners have little knowledge about rare diseases so that information had to be acquired from other sources.

CONCLUSION: To ensure an appropriate knowledge transfer for patients with rare diseases as well as their family members easily-comprehensible and needs-based information are required. This information must be adapted to peoples` needs regarding medical information, social law aspects and practical issues in everyday life. Due to the large number of rare diseases family practitioners do not have practical knowledge about all of them, but should be informed about reliable information sources and specialized institutions.

Weakness and lumbar pain

Paola Lievano, David Idoipe, Alvaro Irigoyen, Jesus Tenias, Carlota Canet, Miguel Lopez Del Pueyo, Sara Lainez, Jose Antonio Ibañez, Laura Urieta, Amparo Cantin, Oscar Zepeda, Miguel Rivas
Community & Family Medicine. Sector III. Hospital Clínico Universitario Lozano Blesa, Zaragoza, Spain.

Background & Aim

Weakness is a frequent nonspecific complaint that includes a wide differential diagnosis which include neurologic disorders and a variety of non-neurologic conditions.

The identification of potential life-threatening neurologic and neuromuscular processes involves a methodical, anatomic approach established upon a medical history, physical examination, and in determines cases, imaging studies.

Method

A case of a 75 year-old man, with weakness and paresthesias since two days ago, back pain, bilateral leg weakness and numbness. Examination shows urinary retention, Lhermitte's sign, hyporeflexia and decreased foot dorsiflexion, inversion and eversion, and mild weakness of leg abduction. He was sent to Emergency Department to study a possible spinal cord compression.

Results

CT and Bone scan show signs of disseminated skeletal metastatic disease and MRI with images of bone metastasis in T7-T8 and prostate asymmetry. Spinal cord compression could not be confirmed. A prostate biopsy evidenced a poorly differentiated adenocarcinoma. Current treatment in Oncology with a palliative treatment of advanced prostate cancer.

Conclusions

Frequent causes of cord compression are tumours, but abscesses and granulomas (e.g. in tuberculosis) are similarly capable of producing the syndrome.

Tumours that generally cause cord compression are lung cancer (oat cell type), prostate cancer, breast cancer, renal cell carcinoma, thyroid cancer, lymphoma and multiple myeloma. It was possible to standing involvement of prostate cancer. An effective and appropriate primary care focus it can be decisive to a right diagnosis.

"{"An Overview to Our Patient Profile "}"

Gülseren Oktay, Ramazan Tetikçok, Nagihan Yıldız Çeltek, Ufuk Ünlü
Department of Family Medicine, Gaziosmanpaşa University, Tokat, Turkey

""AIM: In our study we purposed to increase quality of providing policlinic service and to contribute to the family medicine specialty training by examining the demografic data,reference reasons, diagnoses,reference frequency and coming for checking of patients who refer to the Gaziosmanpasa University of Family Medicine Policlinic.

METHOD: Patients who refer to Gaziosmanpasa University of Family Medicine Policlinic between the date of 01.04.2013 -31.03.2014 were evaluated retrospectively, according to patients' demografic data, reference reasons, diagnoses, reference frequency and coming forchecking.

RESULTS: The avarage age of the patients was 29,436+13.66. Of our patients, 65,5 % were males and 14,3 % were instution staff. 79,06 % of the patients refered once in this one-year period. The most common 3 diagnoses were; 1. Upper respiratory infections, 2. General health examinations and demand health report, 3. Anemia (iron deficiency anemia, vitamin B12 deficiency anemia, etc.).

CONCLUSIONS: Patients who refer for health report and general health examinations are second the most encountered patient group. So, our patient profile is composed of healthy populations frequently. Finally, at the end of family medicine specialty training, it is aimed to graduate doctors who can detect normal and pathologic conditions, and redirect to relatd department when it is necessary. This can be enable only via specialty training which combined family medicine and rotations. "".

Erectile dysfunction in Portugal: an uncovered reality

Diana Vaz De Miranda¹, Bruno Vaz Silva², Diogo Carvalho³, Vanessa Da Cunha Alejos³

¹Unidade de Saúde Familiar S. Nicolau, Guimarães, Portugal

²Unidade de Saúde Familiar Novos Rumos, Vizela, Portugal

³Unidade de Saúde Familiar Ara de Trajano, Guimarães, Portugal

BACKGROUND:

Erectile dysfunction (ED) is defined by the constant inability to obtain or maintain an erection, allowing sexual activity, for at least 3 months. In Portugal, the prevalence is around 10-48%. This problem remains a taboo, that affects men of any age, with a strong impact in their quality of life.

AIMS:

Determine the number of cases of ED in 3 Portuguese Units of Family Health (UFH) and compare it with the Portuguese reality.

Characterize the patients in terms of age, cardiovascular (CV) risk factors and events, depression and treatment for ED.

METHODS:

Observational, descriptive and transversal study.

The populational sample were male registered in the UFH, aged between 18-75 years-old diagnosed with the code Y07-Impotence NOS of the ICPC2.

Data were gathered in September 2014, from clinical records using the electronic medical record system SAM[®], and the statistical analysis was performed using Microsoft Excel 2007[®].

RESULTS:

15568 patients were included in the study. The prevalence found was 1,13%, and the average age was 56 years-old. From these individuals, 49% presented with dyslipidemia, 43% hypertension and 29% with type 2 diabetes. 28% of them were smokers, 68% drank alcohol and 76% were overweight/obese. Approximately 6% have had a CV event and 22% present with depression. In 60% of the cases, no pharmacological treatment was prescribed and when it was, Tadalafil was the first choice (59%).

CONCLUSIONS:

This study revealed a much lower prevalence than the national reality, wich may be explained by the restrain in approaching this pathology or in errors in the clinical registration. A higher prevalence of ED was found in patients over 50 years-old and a high prevalence of CV risk factors were associated with ED, which goes according to literature. It is imperative a reflection on this theme and its correct management in Primary Health Care.

Antibiotic Resistance Rates in Enterobacteriaceae Among Syrian Refugees Seeking Health Care in Turkey

Cahit Özer¹, Burcin Özer², Melek Inci², Funda Çimen², Kemal Jenedi², Nizami Duran²

¹Mustafa Kemal University School of Medicine Department of Family Medicine, Hatay, Turkey

²Mustafa Kemal University School of Medicine Department of Medical Microbiology, Hatay, Turkey

Background and AIM:

Hundreds of thousands of people became refugees because of civil war in Syria and moved mostly to cities near to Syrian border in Turkey. Of these, Hatay hosted approximately three hundred thousand people. This gross population movement might have some negative impacts on health of refugees and people in hosting countries. Not only diseases such as malaria, arbovirus infection, blood-borne viruses such as the human immunodeficiency virus, hepatitis but also multiresistant bacteria are a growing concern in these intercountry patients. We aimed to examine the antibiotic resistance rates among Syrian refugees, who sought asylum in Turkey and compare to Turkish patients.

METHODS:

In this cross-sectional study data of samples sent to microbiology laboratory of a university hospital from 2011 to 2013 was retrospectively analyzed. Antibiotic susceptibility rates in Enterobacteriaceae were compared according to nationality.

RESULTS:

Of the samples sent in three years period 1934 bacteria belong to Enterobacteriaceae were isolated. Two hundred forty eight (12.8%) of these were in Syrian. Almost 4/5 of the samples were sent from surgical departments in Syrian, while the ratio was 1/2 in Turkish. 155 (62.5%) of them were wound samples in Syrian, while 416 (64.9%) were urine in Turkish. Most isolated bacteria were Escherichia coli in both groups (66.5% vs. 70.6%).

Most antibiotic resistance rates in Enterobacteriaceae were observed against ampicillin, cefuroxime, ceftazidime, cefepime and ceftriaxone were 93.0%, 84.3%, 82.6%, 79.3% and 78.9% respectively in Syrian, while it was 84.0%, 57.0%, 52.4%, 49.7% and 49.8%, respectively in Turkish. All rates were higher in Syrian patients than Turkish ($p < 0,001$).

CONCLUSIONS:

Antibiotic resistance rates among Syrian refugees were higher than Turkish patients. That might be due to inappropriate use of antibiotics and wound infections during civil war. Transmission of resistance genes between populations should further discussed and studied.

BACKGROUND:

The Vasco da Gama Movement organises an annual meeting just a day before the WONCA Europe Conference, in which participants coming from all over Europe have the exceptional opportunity to communicate, convey their own points of view and broaden their horizons while learning from other countries, cultures and contexts.

AIM:

Present the outcomes of this PC, including the mini-exchange that took place.

METHOD:

Study and evaluation about number of mini-exchange and PC participants, as well as the results of a questionnaire distributed to them about the PC's activities.

RESULTS:

We've had 18 mini-exchange participants, and 144 participants: 92 at discussion groups, 29 in the Europe Council meeting, 11 facilitators, 3 speakers, 3 invited VdGM important personalities and 6 organizing committee members.

Participants answered some questions related to how they found about the preconference, their overall satisfaction and the one concerned with facilitators, aspects that were positive and the ones that should be improved.

This results will be presented with graphics and images in the poster.

It was presented de 10th anniversary celebration book of the VdGM as well as the Lisbon's statement from VdGM, according to the discussions that took place on the groups.

CONCLUSIONS:

Participants were very engaged with the goal of the PC and with each other. By the feedback given, it seems like the PC goals were fulfilled, besides the fact there are some points to be improved.

Suggestions for the future:

To give the opportunity to more and more trainees and young GPs to participate in this experience, and to optimize its organization, concerning the participant's needs and a flow work to help future organizing committees.

Improving the communication by instant messaging in a health centre in Barcelona

Mireia Leal Negre, Carles Alvarado Montesdeoca, Cecilia Doménech Rodríguez, Arantxa Castillejos Ruiz, Cecilia Vidaurreta Gracia

Molí Nou, Institut Català de la Salut, Sant Boi de Llobregat, Barcelona, Spain

Having a well-established communication system is difficult for any business; however, it is key to success in the workplace.

The effectiveness of communication can be diminished by physical, physiological, or psychological noise, which can exist within either the sender, receiver, or channel.

Our health centre is composed by two different buildings and we are continuously interacting between patients, desk workers, general practisers, nurses, and other members of the staff. Something that happens very often is that while we are visiting our patients the process is not as correct as should be because it is being interrupted as the telephone rings or our colleges break into the room because some help is needed, which is very annoying and disappointing for the patient as this interruptions makes them feel that we are not focus on them. So, to improving both communications between the members of the team and with the patient we implemented the office communicator which allows us to communicate and collaborate easily with other members of the team in different locations by instant messaging in our computers and we analysed the results one year after the implementation with an anonymous survey.

The study shows that a 93,75% of our workers use the tool every day while a 6,25 use it weekly. There are no differences in using it by ages or occupational category (General practicers, nurses or desk staff). Office communicator achieve a score of 8,8 out of 10 points, and 81% prefers office communicator to telephone, a 16% prefers telephone and the other 3% does not matter.

This way of communication has improved both communications, with our patients as the visit is not constantly interrupted by other professionals and with all the staff as it is a quick and non invasive way of talking while we are working.

The most common main reasons for patients visiting family medicine doctor

Sedina Bosankic¹, Samira Herenda², Dušanka Becirovic¹, Mirsada Pamukcic Crnogorcevic¹, Senada Hrcic¹

¹Department of family medicine, Health center, Zivinice, Bosnia and Herzegovina

²Department of family medicine, Health center, Tuzla, Bosnia and Herzegovina

INTRODUCTION: doctor visit is every patient contact with the doctor. The main reason is the reason for the visit by the evaluation of a doctor.

OBJECTIVE: To determine the most common reasons patients visit a doctor.

METHODS: The sample consisted of 354 (81 man i 273 woman) patients who during a calendar month visited a doctor. In the form of data collection was recorded each patient visit, the reason for the visit and the number of visits each patient.

RESULTS: A total of 478 visits. Because chronic diseases was 203 (42.47%) visits. A total 100 (20.9%) patients came with the new findings available to the (lab results, specialists) and 61 (12.76%) patient had come for a referral for a check-up at a higher level of care. The next most common reason is pain-22 patients (4,6%) and scheduled check-up – 12 patients (2,5%). All other causes (83 of them) are represented with a total of 17.2%. Most patients (257 to 72.6%) visited the doctor one time, but there were also those who have done it several times (two times occurred 63 (17.8%) patients, by 3 times occurred 20 (5, 65%) patients, 4 had 12 visits (3.39%) patients, and by 5 and 6 had a visit by one (0.28%) patient).

DISCUSSION: The study confirms the fact that the most common reason for doctor visits in Bosnia and Herzegovina chronic disease. Studies in other countries provide a variety of information: National Center for Health Statistics, USA that in the period 2006-2008. shows the main reason for visiting the doctor was acute illness, then prevention activities and chronic diseases are still in third place, research at the Mayo Clinic 2013th shows he of skin disease as the main reason doctor visits.

CONCLUSION: Chronic disease is the main reason for visiting the doctor.

Knowledge and attitude among high school students in West Papua about HIV

Ade Irma P Baibaba¹, Indah Ein F Wainsaf¹, Devi A Iriyanti¹, Florensiana Patiran¹, Marlyn R Ayomi¹, Wisnu G Triwibowo¹, Samuel S Kamale¹, Trianggrid Sara Saa¹, Trevino Aristarkus Pakasi²

¹Faculty of Medicine Universitas Papua

²Division of Family Medicine, Department of Community Medicine, Faculty of Medicine Universitas Indonesia

Background. West Papua as part of Papua Island was high endemic of HIV, which had an impact to general population. It is important to do a promotion and prevention among the young generation to reduce the spreading. The study aimed to describe the existing knowledge and attitude prior to a health promotion done in a high school of Sorong, West Papua.

Method. A questionnaire was distributed to explore their knowledge related with HIV, prevention, and the disease including where to seek medical treatment, prior to a health promotion. The questioned was distributed afterwards to look at the improving knowledge. However this study only reported the first finding.

Result. There were 138 students filling in the questionnaire consist of 40% male and they lived with their parents (87%). About 6% students admitted pre-marital sexual relationship. Only 1 person admitted that had experience using intravenous drug. But 8% of the students were high risk since they were alcohol drinkers. Of all the questions, more than 90% already knew about the spreading of HIV and knew how to prevent it. About 40% only who knew how and where to seek medical treatment when suspected of HIV, and less than 50% knew the health facility, which could provide diagnosis HIV.

Conclusion. Though promotion of HIV has been spread all over West Papua, there were still people in the community who knew where to seek medical care, that might hinder the case finding.

Reporting an adverse drug event - the case for pharmacovigilance

Luís Pinho Costa, Hélder Sousa

Unidade de Saúde Familiar de Fânzeres, Gondomar, Portugal

Most adverse drug reactions are found only after marketing authorization, stressing the need for pharmacovigilance. By collecting information once the drug is marketed, regulators can protect the population from emerging safety issues throughout a medicine's life cycle. Meanwhile, underreporting of adverse events (AE) is common across countries.

We hereby report two cases.

First, a 32 year old woman within a nuclear family in stage III of Duvall's life cycle; had history of two term pregnancies and had been taking desogestrel for the previous 15 months; informed us she got pregnant while on birth control pills; the couple had not planned but desired it, however feared malformations: due to low back pain she had an x-ray done and took diclofenac for a week, before finding she was pregnant. Pregnancy went without complications and a healthy baby was born.

Second case is a 29 year old woman within a nuclear family in phase II of Duvall's; no relevant medical history besides taking desogestrel+ethinyl estradiol since 2002. Came in due to pain in the lower abdominal quadrants for two days; feared being pregnant. She was requested an ultrasound that showed a ruptured ectopic pregnancy and underwent a laparoscopic salpingectomy with removal of tubal pregnancy. Surgery went without complications but may affect the couple's reproductive future.

In both cases there was no obvious cause for the pills' lack of effect. Absence of contraceptive effect is an AE and was notified; causality was deemed "possible" for the first case, and "probable" for the second.

Family doctors deal with AE regularly. Spontaneous reporting together with case reports/series contribute to a better understanding of drugs' safety profiles and generate the warning signs for possible epidemiological investigations and measures to minimize risks. This work aims to raise awareness among family doctors for their role in this process.

Clinical equivalence of Generic and Brand-Name Drugs used in Hypertension- a Systematic Review and Meta-Analysis

Ana Paula Fonseca, Isa Cruz, Márcia Soares

USF Cruz de Celas

Background and Aim

Regardless of the bioequivalence between the generic and brand-name drugs, concerns about their clinical equivalence remain unclear. We aim to conduct a systematic review and meta-analysis to summarize the evidence until now, to clarify the efficacy of both groups on blood pressure reduction, cardiovascular events prevention and adverse events rate.

Methods

The Cochrane CENTRAL and MEDLINE were searched to retrieve potential randomized trials, without using any linguistic or time restriction. We used a query that included terms relating to the type of study, drugs and disease of interest. Studies were included if they reported on a comparative evaluation of 1 brand-name drug and at least 1 generic version. Primarily bioequivalent studies were excluded.

A fixed effects meta-analysis was performed, using RevMan v5.2. Pooled results were presented as Mean Difference with 95% CI.

Results

The search done in October 2014 identified 1332 records. After removing overlapping citations and applying our exclusion criteria, 5 studies were included. All were crossover studies, involved 159 hypertension subjects and included Perindopril, Ramipril, Amlodipin, Valsartan and the association Bisoprolol/Hydrochlorothiazide. The systolic pressure Mean Difference between Generic and Brand-name groups was -1.04mmHg (CI 95% -4.04 to 1.97) on the first month and -0.22 mmHg (CI 95% -2.16 to 1.72) on the second month. In the same way, the diastolic pressure Mean Difference was -0.06 mmHg (CI 95% -2.19 to 2.07) on the first month and -0.90 mmHg (CI 95% -0.64 to 2.45) on the second month.

None of the included studies reported cardiovascular events or significant differences in the adverse events presented.

Conclusions

The majority of the studies we identified included small populations and were powerless to assess differences in clinical outcomes. Despite these limitations, our results suggest that it is reasonable for physicians to rely on generic drugs.

Organization of a VdGM Preconference step-by-step

Catarina Matias¹, Ana Nunes Barata², Rita Lopes³, Pedro Azevedo⁴, Nuno Jacinto⁵

¹UCSP Juíz de Fora, Mortágua

²USF Amora Saudável

³USF Ouriceira

⁴USF Fânzeres

⁵USF Salus

BACKGROUND:

The Vasco da Gama Movement organises an annual meeting just a day before the WONCA Europe Conference, in which participants coming from all over Europe have the exceptional opportunity to communicate, convey their own points of view and broaden their horizons while learning from other countries, cultures and contexts.

AIM:

To present a work flow concerning the organization of a VdGM's PC, as well as give the possibility to trainees/young GPs to be aware they can be a part of it as volunteers.

METHOD:

We are going to make a short description of the main aspects that an organizing committee has to have in mind in the different parts of the planning and organization process.

We will enhance the fact that more "hands" helping facilitates the process and it is enlightening for all parts: development of communication, organization, team work and leadership skills.

After the inicial description, we will present all the information in algorithm formats in order to make all the process easier.

CONCLUSIONS:

The work flow is now presented and can help other organizing committees in the future.

The algorithm structure can give the organizers a broader idea of all the process in a short time and make them realise it is not an "impossible mission".

This is also gather more trainees/young GPs and make them learn with each other, because they share experiences and ideas together - the VdGM's spirit!

To the future:

Enhance the fact that it is a continuing process: this presentation's aim is to be an inicial tool, that was to be kept updated.

P-1317**The Association Between Body Mass Index and Serum Lipid Concentrations in Overweight and Obese Patients**

Nazli Sensoy, Gulsah Sari, Mehmet Yilmaz, Serdar Mingir

Department of Family Medicine, Afyon Kocatepe University, Afyonkarahisar, Turkey

AIM: Obesity is associated with hypertension and dyslipidemia caused by changing eating pattern, life style and activities. The aim of the study is to investigate correlation between body mass index and serum lipid concentrations of participants.

MATERIAL-METHODS: A total of 251 participants were enrolled in this study, which was conducted in Kocatepe University Hospital. In the present study, age, sex, height and weight demographics of participants were gathered, their body mass indexes (BMI) were calculated. According to their BMI participants were divided into 2 groups, overweight (BMI<30 kg/m²) and obese (BMI>30 kg/m²). Serum tryglyseride (TG), total-cholesterol (TC), high density lipoprotein (HDL), low density lipoprotein (LDL) and very low density lipoprotein (VLDL) cholesterol levels were measured in fasting blood samples and compared in both of the groups. For statistical evaluation, data was analyzed using SPSS 18.0 programme. Chi-square test, Kruskal Walls test, and Mann-Withney U test were used for analyses, p levels <0.05 were accepted as statistically significant.

RESULTS: According to our results, the mean of ages was 31.73± 0.75. Of all participants, 37.1% were overweight, 62.9% were obese. We have found that the main factors on obesity were age, occupation, education, marriage. There was statistically significant difference between overweight and obese with respect to the lipid parameter calculations (p<0.05). It was found that TG, TC, LDL, and VLDL values were relatively low in overweight group, however HDL values was high in overweight group in comparison with obese group (p<0.05). There was significant difference between age groups with respect to the lipid parameter calculations. Lipid values were lower in 17-24 ages groups than others ages groups.

CONCLUSION: There were significant differences in serum lipid concentrations between overweights and obese subjects. Because of wrong dietary habits and sedentary life, obesity develops followed by blood lipid abnormalities.

Keywords: Body Mass Index, Obesity, Serum Lipid Concentration

Table 1. Relationship between body mass index and lipid profile in participants

	BMI 25.0-29.9 kg/m ² (n=93)	BMI ≥30 kg/m ² (n=158)	p
FASTING BLOOD GLUCOSE	89.90±6.68	95.67±11,75	0.000
TOTAL CHOLESTEROL	168.48±37.22	180.16±36.96	0.004

The importance of self-exploration

Alexandru Claudiu Coman¹, Madalina Daniela Graure¹, Juana Flores Torrecillas¹, Florentina Guillen Cavas¹, Enrique Pagan Dato¹, Rosa Requena Ferrer¹, Emiliano Esteban Redondo², Encarnacion Esparza Perez¹

¹Cartagena Casco Health Center, Cartagena, Spain

²Occupational Health Department, University Hospital Santa Lucia, Cartagena, Spain

• Background & Aim

A 29 year-old male consults his general practitioner for discomfort in the right testicle in the last month, referring a little "bump". No other symptomatology.

Medical history: adenoidectomy. Familiar history: grandmother with uterus cancer, grandfather with urinary bladder cancer, aunt with breast cancer

Physical examination: the palpation of the right testicle was not painful, but there was a nodule of around 2 cm on the superior area. No inflammatory signs. Left testicle was normal.

• Method

Blood analysis: Alpha-fetoprotein (AFP) 1 ng/ml, Beta-HCG 0 mUI/ml, LDH 178 UI/L. The rest was normal
Testicular ultrasonography informs of a solid lesion 2.3X1.9X2 cm in the superior area of the right testicle, impressing of a primary tumor.

The patient is remitted to the Urology department where a surgical treatment is performed (right orchiectomy).

The Pathology report informs of embryonal carcinoma

To evaluate the extension a CT-scan of the thorax, abdomen and pelvis was performed, being the result normal.

• Results

Diagnosis: Embryonal carcinoma PT1N0M0S0 of the right testicle

Differential diagnosis: other testicular tumors, testicular torsion, epididymitis.

• Conclusions

The testicular cancer is the most frequent malignant tumor of the young males. The survival rate at 5 years is around 74 % if it has extension to other organs (faraway), 96% if the extension is at near organs and 99% if it is limited at the testicle. The self-exploration is important because a great number of new cases are discovered by the own patients. The diagnosis is realized through ultrasound, and the extension using the CT and scintigraphy. The biopsy is forbidden due to the risk of dissemination. The blood analysis must include tumor markers.

P-1319

When it's more than lower back pain - A Clinical Case

Diogo Silva¹, Diana Costa Marques², Jenny Duarte², Marisa Batarda², Ricardo Vicente²

¹USF Pedro e Inês, Alcobça, Portugal

²USF Tornada, Caldas da Rainha, Portugal

INTRODUCTION:

Lower back pain is a frequent complaint in Family Practice. More than 84% of adults present lower back pain at some point in their lives. In the majority of cases, these episodes are self-limited and the etiology is mechanical, although other underlying causes may be responsible.

CASE DESCRIPTION:

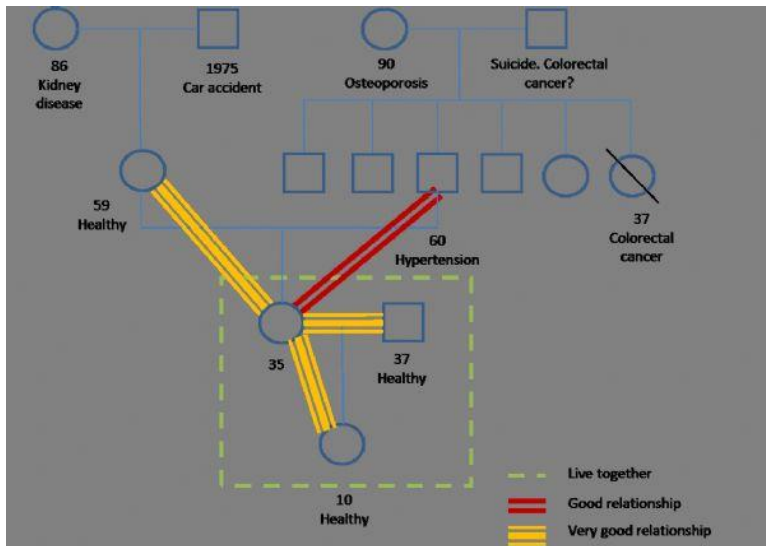

A thirty-five year old Caucasian female, with no previous medical history or any apparent medical indication undergoes both a mammary ultrasound and mammogram. Mammographic findings of the right breast showed a BI-RADS 3 category, recommending follow-up within eight months. Three months later, the patient presents lower back pain and symptomatic treatment is applied, with improvement. As the lower back pain persists, she resorts to an orthopedic physician. After performing various exams, the patient is diagnosed with a poorly differentiated, Invasive Ductal Breast Cancer of the right breast, with lymphatic, axillary and bone metastases and destruction of the L3 vertebral body. Despite undergoing pre-mastectomy chemotherapy and neo-adjuvant radiation, unilateral mastectomy of the right breast and post-mastectomy cycles of chemo-, radio- and hormonal therapy, the patient currently presents metastatic disease of the left scapula and right iliac crest.

DISCUSSION:

Although the majority of lower back pain complaints have a mechanical origin, it is crucial to also have in mind other possible causes, which despite being less common, present poorer prognosis. Moreover, the family physician is instrumental in the management and follow-up during the palliative course and stages of grief of this patient and her family.

Keywords: Lower back pain, Lower back pain etiology, Invasive ductal breast cancer, Breast cancer screening

Nuclear family, Duvall IV, Graffar: middle class, Low familial risk

Exams and Results

DATE	EXAME	RESULT
June/11	Mammogram	Micronodular pattern, of ductal prominence; Microcalcification groupings of the superior quadrant of right breast, one being crude and the others being finer, without secure signs of suspicion, suggesting however, due to the absence of anterior signs, a comparative study. Follow Up with caution within 8 months, to evaluate stability. Right Breast- BI-RADS 3; Left Breast- BI-RADS 2
June/11	Mammary Ultrasound	Small cystic formations, the larger one being elongated and near the left external areolar region
November/11	Magnetic Resonance Image (MRI)	Multiple lesions in T1, T2, D12, L3 and L5 with possible hypothesis of secondary deposits of neoplastic etiology.
December/11	Whole-body Bone Scan	A single bone lesion of the L3 vertebral body, considering as a first hypothesis a predominantly non-fixative /osteolytic lesion of secondary nature.
January/12	PET scan	Hypermetabolic lesions susceptible to: Primary neoplastic lesion of the right breast, with ganglionic disease of the same side; secondary lesions, osteo medullary located, multiple with osteolytic predominance; infracentimetric lesion sited on the liver.
January/12	Biopsy tissue result of right breast	Invasive ductal carcinoma, poorly differentiated (stage 3); Estrogen receptor search: Positive in about 95% of tumoral nuclei; Progesterone receptor search: Positive in about 25% of tumoral nuclei; Immunoreactivity search for HER-2/neu (c-erb-B2) gene and protein: Negative.
April/13	PET scan	De novo lesion of the spinal column as well as the left scapula and right iliac crest.
October/13	MRI	Pulmonary metastases

Case Study Timeline

P-1320

Insomnia: Management in Primary Health Care

Diogo Silva¹, Diana Costa Marques², Jenny Duarte², Marisa Batarida², Ricardo Vicente²

¹USF Pedro e Inês, Alcobaca, Portugal

²USF Tornada, Caldas da Rainha, Portugal

Background & AIM:

Insomnia is the most frequent sleeping disorder in adults and one of the most commonly underdiagnosed medical complaints. Generally it's the family physician whom the patient first resorts to, underlying the fundamental role of primary care physicians in the management of this disorder. The aim of this study is to understand what type of insomnia management is best in primary health care particularly from a therapeutic standpoint.

METHOD:

A bibliographic search was carried out, using Portuguese medical journals, medical databases and the UpToDate search engine, with the terms: insomnia, insomnia management and insomnia in primary health care. Only articles posterior to 2010 were selected.

RESULTS:

Insomnia is a problem that can impair an individual's normal functioning at a social and occupational level, as well during other daytime activities. It can be grouped as acute, chronic or transient insomnia. There are certain factors that increase the risk of developing insomnia as well as specific characteristics that are clinically unique to this disorder. A proper medical anamnesis and physical examination must constitute the patient initial assessment. The association of behavioral therapy with pharmacological treatment seems to demonstrate longer-lasting effects.

CONCLUSIONS:

Being extremely prevalent in primary health care, the adequate management of insomnia by family physicians is fundamental. Some non-pharmacological therapies play a crucial role in insomnia management and should be implemented. The use of drugs should be reserved to situations where non-pharmacological measures prove ineffective.

Keywords: Insomnia, insomnia management, insomnia in primary care, treatment of insomnia

Classification of insomnia

Acute	Chronic	Other types
The symptoms are present for less than 3 months accompanied by significant concern	Symptoms occur at least three times a week and for a period equal to or exceeding three months and not related to an inadequate opportunity for sleep or another sleep disorder	When the criteria do not fit in the other two types
The symptoms may be temporally associated with an identified stress factor		
It disappears when the stress factor is resolved or when the individual adapts to it		

Sleep hygiene recommendations and Stimulus controlling techniques

Sleep hygiene recommendations	Stimulus controlling techniques
<ul style="list-style-type: none"> ✓ Sleep just enough until you feel recovered and then get out of bed 	<ul style="list-style-type: none"> ✓ Go to bed only when sleepy
<ul style="list-style-type: none"> ✓ Avoid looking constantly for hours at bedtime <ul style="list-style-type: none"> ✓ Keep a regular sleep schedule ✓ Avoid forcing sleep 	<ul style="list-style-type: none"> ✓ Do not watch TV, read, eat or talk about concerns while in bed; use the bed only for sleeping or sex
<ul style="list-style-type: none"> ✓ Exercising regularly (at least 20 minutes), preferably 4 to 5 hours before bedtime <ul style="list-style-type: none"> ✓ Avoid caffeinated drinks after lunch ✓ Avoid alcohol close to bedtime ✓ Avoid smoking, especially at night ✓ Do not go to bed hungry 	
<ul style="list-style-type: none"> ✓ Adjust the environment in the room (quiet, dark, safe and comfortable) <ul style="list-style-type: none"> ✓ Deal with concerns before bedtime 	<ul style="list-style-type: none"> ✓ Set the alarm clock to wake up at a fixed time every morning, including weekends
<ul style="list-style-type: none"> ✓ Inform the patient about sleep variation throughout the life cycle 	
	<ul style="list-style-type: none"> ✓ Not perform naps during the day, especially if more than 20-30 minutes or occur in the late afternoon

Therapeutic options in the pharmacological approach of insomnia

Therapeutic options in the pharmacological approach of insomnia			
	Short acting	Triazolam	
Benzodiazepines	Intermediate acting	Estazolam, Lorazepam, Temazepam	Sedative, anxiolytic, myorelaxant and anticonvulsants properties. Decreases sleep latency and the number of nighttime awakenings. Improve length and quality of sleep.
	Long acting	Flurazepam, Quazepam	
Non-benzodiazepines GABA agonists	Zolpidem, zopiclone, zaleplon		Decreases sleep latency and the number of nighttime awakenings. Improve length and quality of sleep. Faster onset and shorter half-lives than the majority of benzodiazepines
Antidepressants	Doxepin		FDA approved at doses of 3 and 6 mg for the treatment of insomnia.
	Amitriptyline, mirtazapine, trazodone		They can be used in the treatment of insomnia when associated with depressive disorder.
Antipsychotics	Quetiapine, olanzapine		They can be used in the treatment of insomnia when associated with psychiatric pathology.
Barbiturics	Phenobarbital, primidone		Not recommended for the treatment of insomnia.
Anticonvulsants	Pregabalin, Gabapentin		Not recommended for the treatment of insomnia in isolation.
Antihistaminics	Not recommended for insomnia treatment. Can trigger psychomotor changes and have anticholinergic effects. Tolerance may developed.		
Melatonin	May be useful in cases where there is evidence of circadian rhythm disorders such as jet lag effect and in patients with reduced hormone levels.		
Melatonin agonists	Ramelteon		Not approved by EMA.
Orexin receptor antagonists	Suvorexant		Approved by the FDA in 2014 but not yet available for clinical use.
Natural products	Valerian		No available studies. Hepatotoxicity? Use is discouraged.

Acupuncture therapies for chronic obstructive pulmonary disease

Ana Lopes Ferreira¹, Renata Almeida²

¹USF Santiago, Leiria, Portugal

²USF São Julião, Figueira da Foz, Portugal

Background & AIM: Chronic obstructive pulmonary disease (COPD) is a global health problem increasingly important, one of the major causes of morbidity and mortality. Is projected to be the third leading cause of death in 2030. Some well-designed studies have found a measured prevalence of COPD in Europe between 4% and 10% of adults in 2003. Acupuncture has been used for more than 2000 years to treat respiratory conditions and may treat COPD effectively.

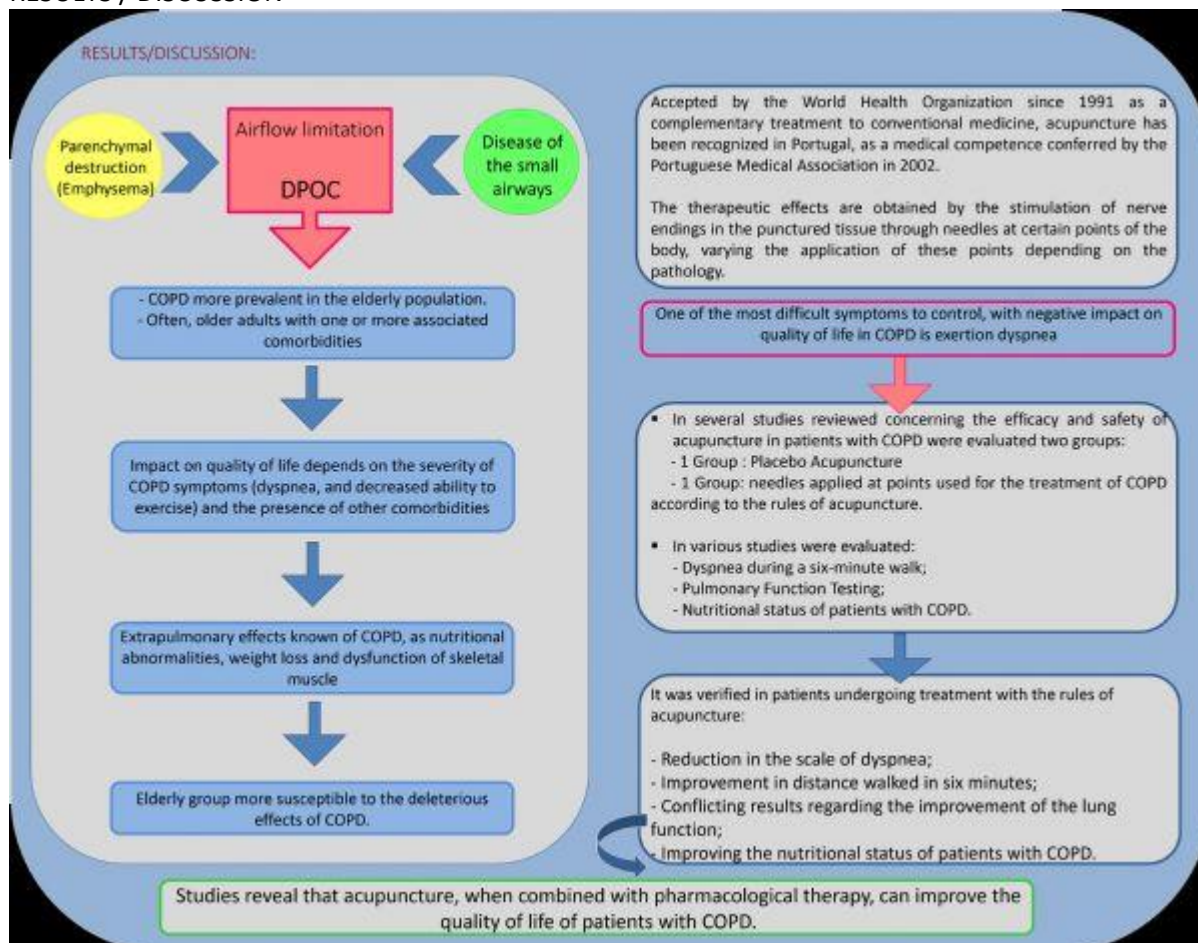

METHOD: The research team made a systematic literature search of scientific articles published in reference databases using the MeSH terms "Acupuncture therapy" and "COPD", of the last 10 years.

RESULTS: The articles found indicate a clinical improvement of dyspnea and quality of life of patients with COPD who performed acupuncture in addition to standard therapy. Other studies have shown that acupuncture can help to improve the nutritional status of patients with COPD, which is an important aspect that influences the prognosis of the disease.

CONCLUSIONS: The review carried out suggests that acupuncture may be an useful complement to standard medical treatment of COPD. However, further studies are needed to be concluded more clearly regarding its benefits, and hence its recommendation in the treatment of COPD.

Keywords: Chronic obstructive pulmonary disease, COPD, Acupuncture therapy

Gastric cancer, a silent disease

Márcia Soares, Isa Cruz, Ana Paula Fonseca

USF Cruz de Celas, ACES Baixo Mondego, Coimbra, Portugal

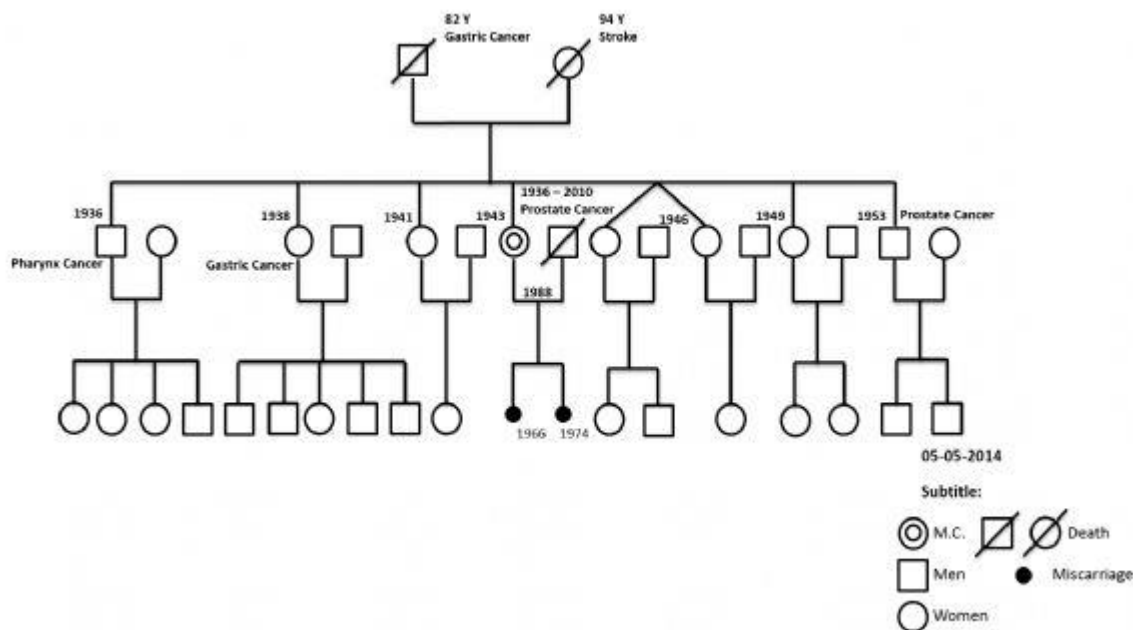

Gastric cancer is the 4th most common cancer worldwide and the 2nd deadliest. Portugal is among the first ten European countries, with the highest incidence and mortality from gastric cancer. This clinical entity in its early stages is, in most cases asymptomatic, whereas in advanced stage of its evolution nonspecific symptoms can be present.

M. C., female, caucasian and widow. Personal history: hypertension, dyslipidemia, overweight and porphyria. Family history: father, 82 years old, passed away with gastric cancer, sister diagnosed with gastric cancer at the age of 68, one brother diagnosed with cancer of the pharynx and the other brother with prostate cancer. In consultation of hypertension surveillance, in April 2014, the patient referred drooling complaint, denying other associated symptoms. The objective examination showed good general condition, normotensive, maintained weight (BMI: 26.8 kg / m²), skin and mucous stained and hydrated and further examination unchanged (particularly, oropharynx, neck, cardiopulmonary auscultation, abdomen). Besides clinical evaluation, an endoscopy was requested, revealing the existence of an "... ulcer in gastric antrum with raised edges and necrotic background of malignant aspect, where biopsy was performed...". The biopsy confirmed the diagnosis of "adenocarcinoma, well differentiated, intestinal type, ulcerated, infiltrating". The patient was at this point referred to surgery consultation, where she is still being followed.

This case reinforces the importance of family background on the context of clinical history, being this, one of the family doctor's task to be attentive to family patterns. In association, monitoring the patient over the years allows us to know the value of clinical complaints, integrated into the patient's personality. In conclusion, gastric cancer is a silent disease, which initial manifestation can be extremely nonspecific, leading sometimes to a late diagnosis.

A Clinical Case of Acute Hypocalcemia

Jenny Duarte¹, Diana Costa Marques¹, Diogo Silva², Marisa Batarida¹, Ricardo Vicente¹

¹USF Tornada, Caldas da Rainha, Portugal

²USF Pedro e Inês, Alcobaça, Portugal

INTRODUCTION

Acute hypocalcaemia can be a life threatening condition, requiring urgent treatment. However, before therapy can be initiated, it is essential to determine the underlying cause so that specific treatment may be carried out. Clinically, patients may be asymptomatic or develop symptoms and signs such as: paresthesia, positive Trousseau and Chvostek signs, spasms and tetany, ECG changes or seizure. Among the various causes of hypocalcemia, the most common is iatrogenic hypocalcemia after inadvertent removal or disruption of the parathyroid glands during total thyroidectomy.

CASE DESCRIPTION

A sixty-one year old female, seeks her family physician after experiencing muscle cramps of the inferior limbs and paresthesia of the hands and perioral region. Eight days before, the patient had been submitted to a total thyroidectomy due to multinodular goiter and was medicated with levothyroxine sodium. Laboratory work is carried out and reveals hypocalcemia and the patient is sent to the hospital emergency room for intravenous (IV) treatment with calcium carbonate. Two days later the patient returns to the emergency room due to paresthesia aggravation, presenting positive Trousseau and Chvostek signs upon physical examination. The patient is hospitalized, IV treatment is done and after receiving histological results of the thyroidectomized tissue, the presence of parathyroid glands confirms the diagnosis of iatrogenic hypoparathyroidism.

DISCUSSION

Iatrogenic hypoparathyroidism associated with a clinical presentation of acute hypocalcemia is a serious complication that should be suspected in a post-thyroidectomized patient. A thorough anamnesis and physical examination is required in order to differentiate between the various causes of hypocalcemia. In family practice a timely diagnosis is crucial in order to achieve a rapid and correct management of this situation.

"I have Macroglobulinemia, and now what?"

Susana Sá, Susana Rios, Miquelina Redondo

Unidade de Saúde Familiar Sem Fronteiras, Agrupamento de Centros de Saúde Entre o Douro e Vouga I, Portugal

INTRODUCTION: The erythrocyte sedimentation rate (ESR) is an analytical parameter which indicates the presence of inflammation. Marked elevations of this parameter should lead to further study, guided by anamnesis and clinical findings. The Waldenström Macroglobulinemia (WM) is a distinct clinical entity characterized by IgM Monoclonal Gammopathy (MG), being asymptomatic in about 25% of the cases. WM is considered incurable and the treatment of asymptomatic patients didn't show benefit in terms of mortality.

Case description: Female, 60 years old. In June of 2009, she recurred to her Family Health Unit and, in the context of the routine consultation, it was prescribed an blood analytical study. In this study, ESR had a value of 89 mm/h. One month after, ESR remained elevated, 94 mm/h. The further study revealed a IgM MG of 26g/L. The patient was sent for additional evaluation in the Haematology Service of the Hospital of the home area. In the course of the study, the patient showed increased anxiety and depressed mood due to the absence of a specific diagnosis. Finally, In April of 2011 the diagnosis of WM was established, but, in the absence of symptoms related to the disease, no treatment was offered. The patient remained anxious, depressed and reluctant in accepting the diagnosis of chronic disease and because of the absence of treatment offered. In March of 2015, the patient is stabilized in relation to her psychiatric health, with acceptance of the disease and reinitiated work activity.

DISCUSSION: The family physician has a crucial role not only in choosing the most appropriate complementary diagnostic exams for their patients, but also in dealing with the abnormal results of these exams. It's crucial not cause harm to the patients, avoiding consequently unnecessary exams. Sometimes, diseases don't have proper treatment, requiring more effort in clarifying and monitoring these cases.

Keywords: Complementary diagnostic exams, erythrocyte sedimentation rate, quaternary prevention

Agomelatine - what is the evidence?

Joana Relva¹, Sara Martins², Sílvia Alves³

¹Canelas Family Health Unit, Canelas, Portugal

²Espinho Family Health Unit, Espinho, Portugal

³Nova Salus Family Health Unit, Vila Nova de Gaia, Portugal

Background & Aim

Major depressive disorder (MDD) is one of the most prevalent diseases in primary health care, responsible for significant demands on service providers in terms of workload and a cause of disability. Therefore, it is urgent to invest in the treatment and prevention of MDD.

Available evidence demonstrates that antidepressants are the elected treatment and that different classes have similar efficacy.

Agomelatine was approved in 2009 in the European Union and has a different and apparently promising mechanism of action, as it is suggested that it improves symptoms by reestablishing circadian rhythm.

The aim of this evidence-based review is to assess agomelatine efficacy in the reduction of MDD symptoms in adults, compared to other antidepressants.

Method

Literature searches were performed in English language publications in several databases - National Guideline Clearinghouse, Canadian Medical Association: practice guidelines infobase, NICE, The Cochrane Library, Bandolier, DARE and Pubmed - from January 2005 to February 2014, using the MeSH terms agomelatine, depressive disorder. Only meta-analysis, systematic reviews, clinical randomized trials and clinical guidelines were included. To establish evidence levels and the strength of recommendation was used the Strength of Recommendation Taxonomy (SORT) scale from the American Family Physician.

Results

The review yielded an evidence base of 107 articles. After application of inclusion/exclusion criteria two meta-analysis were selected. Agomelatine did not seem to provide significant advantage in efficacy compared to other antidepressants (SORT B).

Conclusions

The heterogeneity, different and sometimes contradictory conclusions between published and unpublished studies lead to the conclusion that evidence for agomelatine may be influenced by publication bias. Furthermore, it is necessary to take into account the fact that most of the published studies were sponsored by the pharmaceutical company that manufactures agomelatine.

More studies are necessary to produce high quality data concerning the effects of agomelatine in MDD.

Prevalence of pain in a Primary Care clinic consultation. Epidemiological descriptive, observational, retrospective and cross-sectional study

Antonia Espinosa Collado, Miguel Soto Casas

Servicio Andaluz de Salud, Andalucía, España

INTRODUCTION:

The pain, both chronic and acute, is one of the leading causes of healthcare demand. There are few studies that evaluate the real impact in a Primary Care with the rest of pathologies.

Objectives

Primary OBJECTIVE: Percentage of patients reporting pain as a cause of primary consultation and as other current query even if the main pathology.

Secondary objective: the type of pain (acute, chronic, acute or chronic), the source of pain (musculoskeletal trauma, atraumatic, ischemic pain, abdominal, etc) will be evaluated, whether they receive treatment and type of treatment received (paracetamol / NSAIDs, adjuvants, opioids and opioid older children), the use of scales for pain and if, yes, the average pain intensity.

Study design:

It is an epidemiological descriptive, retrospective study, which were collected from the medical history data for processing: Patients who attended the consultation for five days. Technically it is an epidemiological descriptive, observational, retrospective and cross-sectional, not experimental, not Postmarketing single-center study.

RESULTS:

During the analyzed period (5 days) have been a total of 321 patients from a total quota assigned to the Primary Care 1500, corresponding to 21.4% of the total.

Users who presented with pain as the main cause of consultation correspond to 22% of all reported cases. Those with pain as a cause of the current query rise to 42% of the total. Of this group, 43.4% had acute pain, chronic pain 29.4% and 23.5% exacerbation of chronic pain. 22% had no treatment for the pain to get the query and those who came with pain treatment, 79.4% received paracetamol and / or NSAIDs, 46.8% some form of adjuvant, 30, 6% lower opioid and opioid 12.6% higher.

89% of patients with pain has happened VAS scale for assessment of pain intensity. The mean was 6.71 EVA.

Approaching asymptomatic microhematuria

Sara Martins, Catarina Fernandes

Espinho Family Health Unit, Espinho, Portugal

Background & Aim

Significant asymptomatic microhematuria (AMH) is a common incidental finding in routine urinalysis and family physicians are frequently the first ones to identify it.

The aim of this review is to provide a clinical framework of the best evidence available for the diagnosis, evaluation and follow-up of AMH in adults.

Method

Literature searches were performed on English language publications in several databases from January 2005 to February 2014, with selected exclusion criteria being applied.

Results

Microscopic urinalysis is the one reliable test for AMH diagnosis.

Careful history, physical and laboratory examination should be performed. After eliminating or controlling benign identifiable causes, microscopic urinalysis should be repeated. When positive, further investigation is necessary. The presence of dysmorphic erythrocytes, cellular casts, proteinuria and elevated creatinine level should raise suspicion for medical renal etiologies. Therefore, nephrologic referral is mandatory.

Contraindications to radiation, contrast media allergies and renal insufficiency should be assessed. To evaluate the upper urinary tract, multiphasic computed tomography (CT) is the elected imaging procedure. If there are contraindications or low risk factors for malignancy, ultrasonography, noncontrast CT or magnetic resonance urography should be an option. In both cases, urologic referral is necessary.

Cystoscopy is the main procedure for lower urinary tract evaluation.

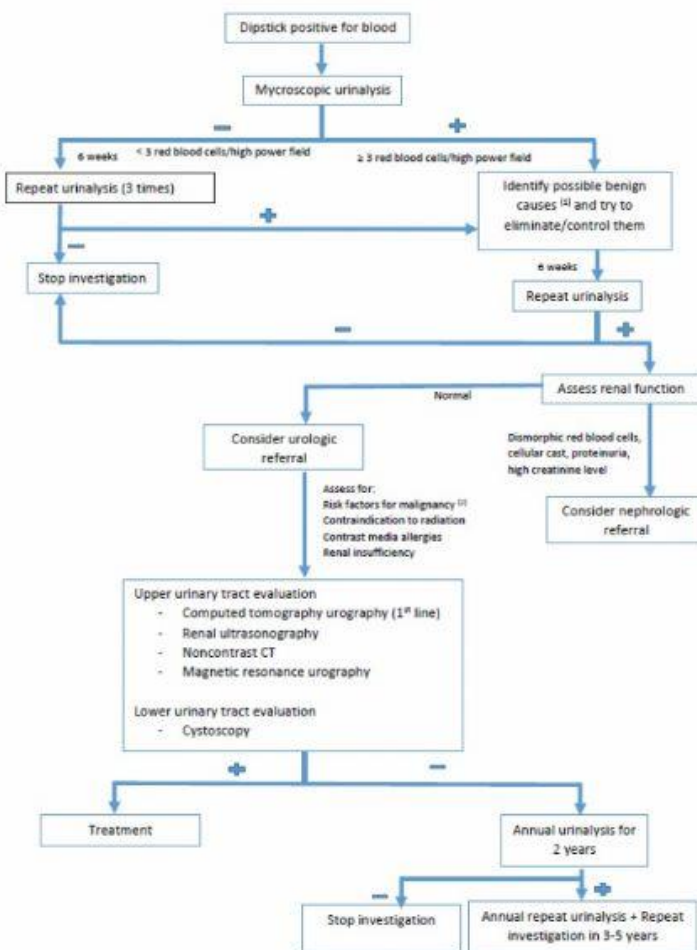

The general accepted timing for follow-up, if appropriate workup does not reveal specific causes, is annual urinalysis for at least two years. If AMH persists, a full repeated evaluation should be considered in three to five years.

Conclusions

There is still lack of evidence to support some of the steps described before. It is necessary to conduct more high quality studies that can clarify the differential radiological evaluation and follow-up timings. Also, one of the priorities should be to clearly define and incorporate a malignancy risk stratification in the clinical framework of the AMH.

Renal Cell Carcinoma: Clinical or image. Discussion on the paradigm change of the renal cancer diagnosis approach

Renata Almeida¹, Ana Rita Feirreira², Joana L. Gonçalves¹

¹USF São Julião, Figueira da Foz, Portugal

²USF Santiago, Leiria, Portugal

INTRODUCTION:

Renal Cell Carcinoma (RCC) is about to 2 a 3% of all of the cancers. The incident peak is between 60 and 70 years old, with a ratio of 1,5:1 male to female. More than an half of the RCCs are actually accidentally diagnosed. This is an aspect that has been significantly changed on the approach of these patients during the last decades.

OBJECTIVES:

Literature review of the RCC diagnosis approach.

MATERIALS-METHODS:

Systematic research of the literature guidelines and of the published papers on the last 15 years.

RESULTS:

More than a half of the RCCs are asymptomatic until the diagnosis. Generally, they present small dimensions and in a first stage of evolution; unlike those symptoms of which only 6-10 % displays the classic triad of macroscopic haematuria, flank pain and palpable abdominal mass. Paraneoplastic symptoms (hypertension, weight loss, fever, anaemia) are found in 20-30% of patients with RCC. Since 30% of symptomatic patients already have metastatic disease at the time they are diagnosed. So far there are no screening tests recommended for RCC in people who do not present major risk factors.

DISCUSSION

The RCC is a type of cancer whose diagnosis is particularly difficult to manage during the natural clinical development, RCCs remain asymptomatic and non-palpable for a long period of time. However, in the last decades due to the increased use of imaging techniques, the "accidentally" diagnosis have been increased. It is not

always easy to direct the thinking to the RCC, as is their natural evolution remain asymptomatic for long periods of time, often manifested firstly for many acute situations.

We discuss the implications of diagnostic imaging versus clinical diagnosis.

Congenital afibrinogenemia presenting with hemorrhage during pregnancy

Süheyl Asma¹, Soner Solmaz², Çiğdem Gereklioğlu¹, Aslı Korur¹

¹Başkent University, Department of Family Medicine, Adana, Türkiye

²Başkent University, Department of Hematology, Adana, Türkiye

BACKGROUND: Congenital afibrinogenemia is a rare coagulation disorder with autosomal recessive inheritance. There is a strong association between fibrinogen activity level and the severity of hemorrhage. In this case report, we presented a patient who was admitted with widespread ecchymosis and worsening general condition and diagnosed with congenital afibrinogenemia.

MATERIAL-METHOD: A 25-year-old patient was admitted to our hospital due to widespread spontaneous ecchymosis and poor general condition at 24.week of gestation. No obstetric problems were detected in her initial evaluation however aPTT and INR values were elevated, D-dimer was normal, fibrinogen could not be detected. She was administered fresh frozen plasma, fibrinogen and antibiotic. Rest curettage was applied due to developing vaginal hemorrhage and abortion. Her treatment continued in intensive care unit due to hypoxia and tachycardia, fibrinogen support maintained.

RESULTS: The patient was discharged as hemorrhage did not continue. She is being followed up unproblematically with aPTT >160 sec, INR>11, fibrinogen <0.80 gr/L.

CONCLUSION: Clinical findings of afibrinogenemia varies between minimal and severe hemorrhage. Fibrinogen cannot be detected or minimal in plasma and platelets in afibrinogenemia. Fibrinogen replacement therapy was generally effective in preventing or treating bleeding in doses adequate to achieve and maintain fibrinogen activity above 50-100 mg dL (non-surgical and obstetric use) or 100-200 mg dL (surgical prophylaxis). Obstetric outcomes were optimized when fibrinogen replacement was initiated prior to conception. Uncontrolled hemorrhage, allergic reactions and antibody formation are rare adverse events. Congenital afibrinogenemia should be suggested in patients who have hemorrhage, prolonged PT, PTT. It is of great importance to examine these parameters prior to any surgical intervention.

Keywords: hemorrhage, pregnancy, congenital afibrinogenemia

Investigation Of Some Herbal Extracts' Cytotoxicities

Betül Battaloğlu Inanç

Muğla Sıtkı Koçman University, Faculty of Medicine, Family Medicine Department

AIM: Completely using vegetable oils, non-chemicals and non-alcoholic ingredients, an anti-mosquito repellent, non-irritant for skin and environment, was planned to produce. As a first step, our aim was to investigate the renal cytotoxicity of these extracts which will be used as insecticides was aimed.

METHODS: The all-natural oils obtained from the market were used in 100% concentration. Extracts were prepared, cytotoxicity tests were performed at Istanbul University Faculty of Pharmacy, Laboratory of Toxicology. Extracts were applied to rat kidney epithelial cells to determine the cytotoxicity with MTT test (3-4,5-dimethyl-tiazolil-2,5-difeniltetrazolium bromid).

RESULTS: 0.625% concentrations of 1st, 2nd and 3rd extracts' caused cell death in 93%, 89% and 89%, respectively. Their IC50 doses -inhibitory concentration causing a 50% decrease in cell proliferation- were found 0.265%, 0.256% and 0.041%, respectively.

CONCLUSIONS: First of all, 'If it is herbal, it is safe to use' concept must be once more questioned, and they must be very carefully handled especially if these agents will be used for the humans. Under the IC50 concentrations, the extracts were safe in our study. The repelling time of the extracts produced in these values must be investigated and this periods must be clear. Further studies should be performed in order to use these extracts as new insecticid agents with low toxicity on normal cells.

Important Differential Diagnosis Of Back Pain: Metastasis

Fatih Bağcier, Akın Erdal

Atatürk University Faculty of Medicine, Department of Physical Medicine and Rehabilitation, Erzurum

INTRODUCTION: Acute low back pain is one of the most common reasons for people to see a family doctor. Pain may originate from a variety of musculoskeletal tissues or present as referred pain from adjacent pathology, such as peptic ulcers, pancreatitis, pyelonephritis, aortic aneurysm, and more. Although most patients recover with symptomatic care and physical therapy, proper evaluation is imperative to identify rare cases of serious underlying pathology. We aim to present patient who has low back pain, was diagnosed gastric tumor metastasis. CASE: 65 –year-old female patient was admitted to our clinic with low back pain. Pain did not decrease with rest. She had surgery from stomach cancer three years ago. There was no history of trauma and other diseases. On physical examination thoracolumbar junction was sensitive to palpation. Lumbar disc herniation examination was normal. Atypical appearance was observed in the thoracolumbar junction in conventional radiography. Magnetic resonance imaging T12 and L1 level was consistent with the view of metastatic. Scintigraphy revealed an increase in the level of metabolic activity. As a result spinal metastasis of gastric cancer was diagnosed and were referred to medical oncology.

Introduction: Serious, life-threatening diseases are uncommon causes of back pain; malignancy, ankylosing spondylitis. However, missing such a critical diagnosis represents a serious concern for every practitioner; thus complaints of back pain often lead to multiple imaging studies and consultations. In close to 15% of oncology patients, the primary presenting symptoms of malignancy are related to spinal metastases. In these patients, the most common underlying pathology is lung cancer, followed by breast cancer in females and prostate cancer in male patients. In our clinical practice patient who has history of malignancy, presenting with low back pain; spinal metastases should be considered in differential diagnosis.

Keywords: low back pain, metastasis, gastric cancer

Complex Regional Pain Syndrome: A Case Report

Fatih Bağcıer, Emine Esra Ergül, Ayhan Kul, Meltem Alkan Melikoğlu

Atatürk University Faculty of Medicine, Department of Physical Medicine and Rehabilitation, Erzurum

INTRODUCTION: Complex regional pain syndrome is a symptom complex including severe pain which is disproportioned by the initiating event. It typically affects hand and wrist on the upper extremity. Diagnosis is made according to the history, symptoms and physical findings of the patients. We aim to present patient who has trauma history, had posttraumatic shoulder, hand pain and was diagnosed complex regional pain syndrome.

CASE: 45 year-old male patient was admitted to our clinic because of wrist pain, swelling and limitation of movement. Left forearm of the patient was taken plaster due to the high fracture after falling three months ago. In the physical examination marked edema in the left wrist was observed, while touch was sensitive and joint movement restricted. Conventional X-ray showed osteoporosis in the wrist joints. As a result patients with complex regional pain syndrome was diagnosed. Physical therapy modalities, range of motion, stretching exercises and medical treatment was performed. Patient 's pain reduce and range of motion was normalized.

CONCLUSION: Complex regional pain syndrome is a syndrome that basically contains various traumas in its etiology and the pathogenesis is not fully understood. There are two types of complex regional pain syndrome. Complex regional pain syndrome type 1 (reflex sympathetic dystrophy) occurs after a minor trauma of the extremities whereas type 2 (causalgia) occurs following peripheral nerve injury. Patient education, physical therapy and medical treatment (nsaid, antidepressants, calcitonins, vasodilators, local anesthetics) are effective for treatment. Our patients had a history of trauma and were evaluated as type one. He had seen significant benefit from medical treatment and physical therapy modalities. As a result, in our clinical practice patient who has history of trauma, presenting with severe pain in the hand and shoulder area; complex regional pain syndrome should be in the differential diagnosis

Keywords: wrist pain, shoulder pain, trauma

Avascular necrosis of the knee: a rare case

Fatih Bağcıer, Meltem Alkan Melikoğlu

Atatürk University Faculty of Medicine, Department of Physical Medicine and Rehabilitation, Erzurum

Introduction: Avascular necrosis result of many conditions leading to death of bone cells by the impairment of blood supply. Although associated diseases and conditions (steroid administration, alcoholism, systemic lupus erythematosus, etc.) are well known, avascular necrosis is thought to arise from a multifactorial etiology of mechanical, hormonal and hematologic factors. Although osteonecrosis (ON) is a well-known complication of systemic lupus erythematosus (SLE), the diagnosis is generally delayed. Steroid treatment is considered the major risk factor for the development of ON in SLE. In this report, a patient with SLE who developed avascular osteonecrosis of knee is presented.

CASE: Thirtyfive years old woman who with a known diagnosis of SLE five years was admitted to our clinic with complaints of pain in both knees. Her pain began two weeks ago, there was no history of trauma and accident patients who use hydroxychloroquine day 2x1 posology. Physical examination in both knee medial and lateral epicondyle apparent sensitivity was present. Grade three gonarthrosis was determined in the conventional radiography. Patient's magnetic resonance imaging in both knee osteonecrosis of the femoral diaphysis and distal showing continuity along the medial epicondyle was reported. As a result SLE related secondary osteonecrosis was diagnosed. Twenty sessions physical therapy and medical treatment were underwent. Quadriceps strengthening exercise program was given. Patients were discharged who responded to conservative treatment, decrease in pain and physical examination findings.

CONCLUSION: In patients with systemic lupus erythematosus (SLE) avascular osteonecrosis can occur either because of a complication of treatment (STEROID) or association with antiphospholipid antibody. MRI should be used as first-line diagnostic methods. But may not give finding at an early stage. Early stage it is possible to achieve good clinical results with conservative treatment in patients with secondary osteonecrosis

Ankylosing Spondylitis Family: A Case Report

Fatih Bağcıer, Ayhan Kul, Mahir Uğur

Atatürk University Faculty of Medicine, Department of Physical Medicine and Rehabilitation, Erzurum

Introduction: Spondyloarthropathies are characterised by inflammation of vertebrae, peripheral joints and periarticular tissues. Diseases in this group present with similar clinical features. Etiology is unknown but genetical tendency, infectious agents and environmental factors may play a role. Among many HLA and non-HLA genes, HLA-B27 plays a major role in its etiopathogenesis. Suggested hypotheses for HLA-B27's role in the pathogenesis of AS can be summarized as presentation of arthritogenic peptides to cytotoxic T cells, those peptides presented to T cells which are derived from HLA-B27 itself being arthritogenic, and inflammation due to specific biological characteristics of the HLA-B27 molecule. Here we aim to present the case two of whom were boys axial ankylosing spondylitis and peripheral ankylosing spondylitis was diagnosed mother in our clinic.

CASE: 30 year old female was admitted to our clinic due to a family history in order to have the HLA-B27 genetic test. Patient had no history of active joint pain patients, back pain, heel pain, psoriasis and inflammatory bowel disease. There was no feature in the CV. Both boys had ankylosing spondylitis in family history. When patients present with genetic results after three weeks had active arthritis in his left ankle. HLA-B27 positive. heel spurs were detected in X-ray. As a result, the patient was diagnosed with peripheral ankylosing spondylitis.

Indomethacin treatment was started in 3x1 posology. Regular follow-up was recommended.

CONCLUSION: Questioning the family history in rheumatic diseases as our case is very important. In our clinical practice, patients who have a family history of rheumatic diseases, physical examination, medical history, and family history of inquiry must be made in more detail. Admission even if they are asymptomatic should be monitored regularly.

A Rare Etiology Of Atraumatic Chest Pain: Tietze Syndrome

Fatih Bağcıer, Mahir Uğur

Atatürk University Faculty of Medicine, Department of Physical Medicine and Rehabilitation, Erzurum

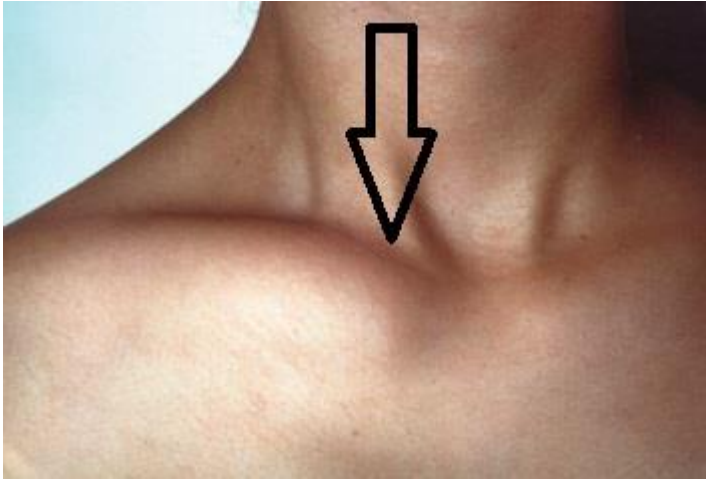

INTRODUCTION: Tietze syndrome(TS) is a benign inflammation of the costal cartilages. The etiopathogenesis of this syndrome is unknown. The diagnosis relies on clinical manifestations and the exclusion of other conditions that affect costal cartilages such as infection, malignancy, relapsing polychondritis and other autoimmune disease processes. We aim to present in this case the patient who has localized chest pain, swelling and diagnosed TS.

CASE: Twentyfive years old college student man was admitted to our clinic with localized pain and swelling in the chest. Patient's who had no known history of trauma, pain was for approximately two weeks. On physical examination, the left sternoclavicular joint redness, tenderness, swelling was observed. Biochemical analysis: Sedimentation: 15mm/saat, CRP: 12 mg / dl, HB: 13,6mg / dL, ALT: 20IU/ml, Creatinine: 0,7mg / dl. RF and ANA were analyzed for differential diagnosis of the autoimmune diseases and resulted in normal. Chest X-ray pathology was detected.Cervical CT showed left sternoclavicular joint narrowing and asymmetry. The patient was diagnosed as TS with these findings. Treatment was begun with nonsteroidal anti-inflammatory drugs. Ten days later in control of paitent who pain and swelling of ongoing, local steroid injection was planned. Pain and swelling reduced significantly and physical examination was normal after injection.

CONCLUSION: TS is characterized by painful non-suppurative swelling of the cartilaginous articulations of the anterior chest wall. This syndrome often mistaken for heart disease. It often results from a physical strain or minor injury, such as repeated coughing, sneezing, vomiting, or impacts to the chest. Patients who have had radiation therapy to the chest/breast will often experience this syndrome which can occur shortly after therapy or years later. Treatment is usually symptomatic. Nonsteroidal anti-inflammatory drugs, ultrasound -guided local steroid injections may effective. Patients who do not benefit from the medical treatment, surgical treatment should be considered.

Vitamin B12 Deficiency Along With Severe Anemia

Mehmet Temurtaş¹, Havva Üsküdar Teke², Uğur Bilge¹, İlhami Ünlüoğlu¹

¹Department of Family Medicine, Eskişehir Osmangazi University, Eskişehir, Turkey

²Department of Internal Medicine, Eskişehir Osmangazi University, Eskişehir, Turkey

INTRODUCTION: Vitamin B12, which is also known as cobalamin, was first identified in 1948 and subsequently was proved to be effective in pernicious anemia. Vitamin B12 deficiency is an endemic cause for macrocytic anemia and elderly population is one of the risk groups in terms of vitamin B12 deficiency.

CASE: 64-year-old male patient. The patient consulted to the epicenter with malaise during the last one week. The patient was referred to our Hematology clinic after his examination resulted as Hgb:3gr/dl Hct:8,8 % mcv:106 fL plt:52000/mm³. Being monitored for anemia etiology investigation and with hemolytic anemia prediagnosis. He did not have any known chronic disease. In the physical examination, no positive symptom was detected except pallor of skin and conjunctiva and subicteric sclera. The patients' examinations in our hospital were resulted as; Hgb:4,4 gr/dl (after 2 units of erythrocyte suspension replacement) Mcv:100fL Mch:33 plt:30000/mm³ T.bilirubin:2,45 mg/dl D. bilirubin: mg/dl Vit B12:45 pg/ml folat:3,5 ng/ml LDH:4348 IU/L direct coombs (-), reticulocyte:3.35% ret index:0,02. In the abdominal USG, biliary sludge was positive (+) and spleen size was normal, additional findings were not detected. Haptoglobin, Alkaline Phosphatase, uric acid, beta-2 microglobulin levels were in normal ranges. Salmonella and brucella examinations were evaluated as negative. Patient was diagnosed as megaloblastic anemia related to Vitamin B12 deficiency, intramuscular cyanocobalamin and folic acid tablet supplementation were given. Erythrocyte suspension replacement was repeated after further examinations. The patient's general condition were evaluated as recovering and his blood values have increased (hgb:7,5gr/dl). The patient was discharged from the hospital with polyclinic follow-up suggestion.

45 Years and Older Patients' Evaluation Of Peripheral Artery Disease With Ankle Brachial Index And Of Quality Of Life With Sf-36: Reliability And Validity Study Of WIQ

Ayla Kara¹, Nilgün Özçakar²

¹Ağlasun Family Health Center, Ministry of Health of Turkey, Burdur, Turkey

²Dokuz Eylül University, Medical Faculty, Department of Family Medicine, Izmir, Turkey

Background&AIM: It was aimed to assess Peripheral Arterial Disease (PAD) with Ankle Brachial Index (ABI) and quality of life with the SF-36 and determine the validity and reliability of Turkish "Walking Impairment Questionnaire" (WIQ).

METHOD: Volunteered 283 participants at a family health center in Izmir Balçova participated in this research. Following the history and physical examination methods by the researcher; ABI values were calculated, determining whether peripheral arterial disease (PAD) and the quality of life were evaluated with scale of the SF-36. By applying WIQ, adapted to Turkish, questionnaire twice with an interval of 2-4 weeks, test-retest analyzes were conducted. And SF-36 was calculated for the relationship between WIQ validity, internal consistency, Cronbach's alpha was calculated. SPSS 15.0 software was used for analysis and p <0.05 was considered significant.

RESULTS: The 11.7% of the patients (33) is found ABI <0.90 is considered as PAD. WIQ compared with SF-36 physical function subscale the relationship was strong, the emotional subscale had weak role and the other subscales were moderately correlated. Cronbach's alpha for internal consistency WIQ the total score was 0882.

CONCLUSIONS: As a result of this study; Turkish version of WIQ was found to be a reliable, valid clinical tool for the assessment of the decrease in walking function of patients with peripheral arterial disease.

Walking Impairment Questionnaire

Walking Impairment Questionnaire (WIQ)

Patient Name: _____

Tacoma (253) 572-7320
 Puyallup (253) 841-4347
 Lakewood (253) 588-7778
 Gig Harbor (253) 851-0404
 Covington (253) 630-3300

Date of Birth: _____

Walking Impairment: These questions ask about the reasons why you are having difficulty walking. We would like to know how much difficulty you had walking during the past week. By difficulty, we mean how hard it was or how much physical effort it took to walk because of each of these problems.

Peripheral Arterial Disease (PAD) Specific Questions

		Degree of Difficulty				
		None	Slight	Some	Much	Very
Pain, aching or cramps in your calves or buttocks?	Right Leg	4	3	2	1	0
	Left Leg	4	3	2	1	0
	Both Legs	4	3	2	1	0

Differential Diagnosis

	Degree of Difficulty				
	None	Slight	Some	Much	Very
1. Pain, stiffness or aching in your joints (ankles, knees or hips)?	4	3	2	1	0
2. Weakness in one or both of your legs?	4	3	2	1	0
3. Pain or discomfort in your chest?	4	3	2	1	0
4. Shortness of breath?	4	3	2	1	0
5. Heart palpitations?	4	3	2	1	0
6. Other problems (please list)	4	3	2	1	0

Walking Distance: Report the degree of physical difficulty that best describes how hard it was for you to walk on level ground without stopping to rest for each of the following distances during the last week.

Distance

	Degree of Difficulty				
	None	Slight	Some	Much	Very
1. Walking indoors such as around your home?	4	3	2	1	0
2. Walking 50 feet?	4	3	2	1	0
3. Walking 150 feet (1/2 block)?	4	3	2	1	0
4. Walking 300 feet (1 block)?	4	3	2	1	0
5. Walking 600 feet (2 blocks)?	4	3	2	1	0
6. Walking 900 feet (3 blocks)?	4	3	2	1	0
7. Walking 1500 feet (5 blocks)?	4	3	2	1	0

Walking Speed: Report the degree of difficulty that best describes how hard it was for you to walk one city block on level ground at each of these speeds without stopping to rest during the last week.

Speed

	Degree of Difficulty				
	None	Slight	Some	Much	Very
1. Walking one block slowly?	4	3	2	1	0
2. Walking one block at an average speed?	4	3	2	1	0
3. Walking one block quickly?	4	3	2	1	0
4. Walking or jogging one block?	4	3	2	1	0

Stair Climbing: For each of these questions, report the degree of physical difficulty that best describes how hard it was for you to climb stairs without stopping to rest during the past week.

Stairs

	Degree of Difficulty				
	None	Slight	Some	Much	Very
1. Climbing one flight of stairs?	4	3	2	1	0
2. Climbing two flights of stairs?	4	3	2	1	0
3. Climbing three flights of stairs?	4	3	2	1	0

Cheap, Available Inflammatory Marker: Main Platelet Volume(Mpv)

Fatih Bağcier, Meltem Alkan Melikoğlu

Atatürk University Faculty of Medicine, Department of Physical Medicine and Rehabilitation, Erzurum

Introduction: C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) are commonly used assays for measuring acute phase response, but CRP and ESR are influenced by several factors unrelated to inflammation. Mean platelet volume (MPV) is a simple marker of subclinical inflammation. In this study, we aimed to investigate the correlation between MPV and clinical activity indices, namely Systemic Lupus Erythematosus Disease Activity Index SELINA in patients with SLE.

MATERIALS-METHODS: 48 SLE patients (16 active, 32 inactive) were enrolled in the study. Disease activity was determined by Systemic Lupus Erythematosus Disease Activity Index in SLE patients. MPV, PDW, PTC parameters were evaluated. Age and gender- matched 37 healthy subjects were used as the control group.

CONCLUSION: In total, 48 patients (1 males and 47 females) were enrolled in this study. The patients were grouped as Group 1 with control group and Group 2 under remission and group 3 active disease. There were 37 (43,5%) patients in Group 1, 32 (37,6%) patients in Group 2 and 16(%18,8) patients in group 3. The plateletcrit, MPV and PDW values were not seemed to be higher or lower during active disease. In our data unlike the studies of the literature, PTC was not found to be a positive acute phase reactant and MPV and PDW were not negative acute phase reactants in patients with active SLE.

DISCUSSION: These new platelet indices are now widely available and are also cheap, clinicians should wonder about their importance. In our retrospective trial, we analyzed 48 patients with SLE and compared their results with 37 healthy patients. Unlike was expected, these new indices were not valuable parameters for active disease. New trials should be done to support these results. We believe results of our study would be meaningful to do greater number with the patient.

P-1339

May Be A Sign Of Systemic Disease: Erythema Nodosum

Fatih Bağcıer¹, Ayhan Kul¹, Murat Alkan², Nilgün Özçakar²

¹Atatürk University Faculty of Medicine, Department of Physical Medicine and Rehabilitation, Erzurum

²Dokuz Eylül University Faculty of Medicine, Department of Family Medicine, İzmir

INTRODUCTION: Erythema nodosum (EN) is the most frequent form of panniculitides. EN is associated with many underlying etiological conditions. In about 30-50% of cases, the cause of EN is unknown EN may also be due to infection, autoimmune disorders, pregnancy, medications, cancer. We report a case of EN etiology can not be determined.

CASE: A 15-year-old male patient presented with multiple painful, coin-sized, erythematous nodules over extensor side of bilaterally lower leg for a week. He was referred to the our clinic by the family physician for rheumatic diseases. There was no concomitant fever, hair loss, or joint pain. facial erythema, dryness of eyes and mouth, and oral ulcers, photosensitivity, raynaud's phenomenon, genital ulcers, and serious inflammation of eyes were never noted. The patient denied any major systemic disease in the past. She was not taking any medication when she presented at the outpatient clinic. Physical examinations were unremarkable, except for a tender erythematous induration, about 1 cm in diameter, over the extensor side of bilaterally lower leg. Urinalysis and serial blood tests, including complete blood count/differential count, erythrocyte sedimentation rate, C-reactive protein, antistreptolysin-O and autoimmune markers were all negative. Erythema nodosum was diagnosed. Anti-inflammatory drugs and rest was recommended.

CONCLUSION: EN is associated with a wide variety of conditions such as infection(Streptococcal infection, tuberculosis, mycoplasma pneumoniae), autoimmune disorders(inflammatory bowel disease, behçet's disease, sarcoidosis), pregnancy, medications(sulfonamides, penicillins, oral contraceptives), cancer(non-hodgkins lymphoma carcinoid tumours, pancreatic cancer). But in about 30-50% of cases, the cause of EN is unknown. Erythema nodosum is self-limiting and usually resolves itself within 3–6 weeks. Treatment should focus on the underlying cause. Symptoms can be treated with bedrest, leg elevation, compressive bandages, wet dressings, and nonsteroidal anti-inflammatory agents. in our clinical practice in patients with EN systemic questioned and physical examination must be evaluated carefully.

A case of beta blocker induced psoriasis

Selçuk Akturan

Family Medicine Polyclinic, Tercan State Hospital, Erzincan, Turkey

36 years old men, a Coronary Artery Disease patient and he had coronary artery bypass surgery 2 years ago (2013). He had a history of psoriasis lesions after using metoprolol after CABG, so he had stopped to use metoprolol. After that atorvastatin, clopidogrel were given to him, than he had used regularly these medications. In September 2015, another beta blocker, nebivolol was started to him. One month later, he consulted Tercan State Hospital Family Medicine Polylinic because of erythematous, itchy, swollen, white psoriasis plaques on both of eyelids, external surface of both arms for 3-4 days. Psoriasis is a chronic, inflammatory, immun-mediated skin disorder. Some factors known to trigger psoriasis include smoking, alcohol, body mass index, infection, endocrine disorders, drugs, and acute withdrawal of corticosteroids. Some of the most common medications know to trigger or worsen existing psoriasis include lithium, gold salts, beta blockers, ACE inhibitors, chloroquine, and NSAIDs. We stopped to use nebivolol and 2 weeks later we observed that the lesions were improved. We added a calcium channel blocker medication instead of beta blocker.

Keywords: beta blocker, psoriasis, medication

Approach to the Patients Who Applied to Atyam (Alternative and Complementary Medicine Center)

Sultan Oksuz Zortul¹, Abdulsemet Zortul², Yasemin Çayır¹, Fatih Akçay³, Özlem Özer¹

¹Department of Family Medicine, Ataturk University, Erzurum, Turkey

²Department of Radiation Oncology, Ataturk University, Erzurum, Turkey

³Department of Biochemistry, Ataturk University, Erzurum, Turkey

Acupuncture is a form of alternative medicine involving the stimulation of specific acupuncture points along the skin of the body using thin needles. It can be associated with the application of heat, pressure, moxibustion or laser light to these same points. Clinical practice varies depending on the country. According to the theories of traditional chinese medicine (TCM), stimulating acupuncture points corrects imbalances in the flow of Chi through channels known as meridians.

We aimed to show conditions that acupuncture are preferred.

A retrospective review was performed of the medical records of conditions that acupuncture are preferred. We examined data derived from 180 patient who had experienced at least 1 session of acupuncture at ATYAM.

Of 180 patient records identified. % 72 female (n=130), % 28 male (n=50), mean age was 44±14, mean number of session was 9±7, % 55 (n=111) healed, %52 (n=95) continued to treatment.

TCM explains acupuncture as a technique for balancing the flow of energy or life force (Chi). It's based on the theory that energy flows through and around your body along pathways called meridians. Acupuncturists believe that illness occurs when something blocks or unbalances Chi. Acupuncture is a way to unblock or influence Chi and help it flow back into balance. Acupuncture is practiced worldwide both as a primary and adjunctive treatment for a wide range of conditions. Some of the more commonly treated conditions are; pain in the body including headaches, migraines and trauma, psychological related conditions such as depression, anxiety and insomnia, menstrual issues such as premenstrual syndrome, amenorrhea, irregular menstruation, asthma and allergy issues. Pain may be resolved not only through antinociceptive effects but also by reversing the emotional feeling of pain from unpleasant to pleasant. We have found similar datas (figure-1,2). Acupuncture was preferred mostly for diseases; migrain and mechanical pain.

The most spread teleophthalmology application is retinopathy screening in diabetic patients.

Its main objective is to prevent blindness, the most severe ophthalmologic complication of diabetics and, on the other hand, to improve patient accessibility to the diagnostic tests and to their reference ophthalmologists. Besides, diabetic retinopathy screening allows the diagnosis of other prevalent ophthalmologic pathologies in our diabetics as cataracts, age related macular degeneration, papillary abnormalities, epiretinal membranes, nevus... An experience of a diabetic retinopathy screening programme applied to 400 patients in a rural health area is presented. The exploration of the ocular fundus with non-mydratic retinograph, under pharmacologic mydriasis, allows the diabetic retinopathy diagnosis, its type and its severity degree, allowing also to establish its interrelationship with the two most important progression factors, time of diabetes evolution and illness metabolic control degree.

On the other hand, teleophthalmology allows new possibilities on the approach of ophthalmologic pathology in rural primary care health centres, avoiding unnecessary patient referrals to ophthalmologists. It would be desirable a suitable equipment in primary care health centres, consisting of optotypes, tonometer, grid Amsler and retinograph, as well as an appropriate ophthalmologic training of the professionals and besides, interdisciplinary work among professionals of the different assistance levels to improve the quality of the assistance patients receive and to improve their satisfaction level.

Prevalence and characteristics of musculoskeletal injuries in Lebanese elite track and field athletes

Lana El Osta, Abdo El Helou, Habib Aimé Hatem, Nazek Saadallah, Nada El Osta

Department of Public Health, School of Medicine, Saint-Joseph University, Beirut, Lebanon

BACKGROUND AND AIM: Sports participation involves a certain risk of injuries that might lead to long-term or even permanent disability. It is interesting to acquire knowledge regarding sports injuries, to help planning injury prevention programs.

This study aims to determine the prevalence and to describe the characteristics of musculoskeletal disorders among Lebanese elite track and field athletes.

METHODS: A retrospective cross-sectional survey was conducted among an eligible study population of 250 athletes. Data were collected through an anonymous structured questionnaire assessing self-reported injury data from participants. An athletics injury was defined as musculoskeletal condition that made the athlete partially or completely abstain from training or competition in track and field for a 1-week minimum injury period during the past year.

RESULTS: A total of 210 athletes completed the questionnaire (response rate: 84%): 60.5% were male, and the mean age was 25.51±6.71 years. The participants were categorized into event groups: sprints (17.6%), middle and long distances (49.5%), throws (10.5%), jumps (11.9%), and combined events (10.5%). The 1-year retrospective injury prevalence was 51.9% (95% confidence interval, 45.14%-58.66%). Thirty-one respondents reported injuries to 2 body regions, and 5 others reported injuries to more than 2 regions. Most of the damages affected the lower extremities (85.3%), mainly hip, groin and thigh (34.0%), and were associated with a sudden onset (66.7%). The most frequent types were contractures (35.33%) followed by sprain/strain/rupture (28.0%).

The multivariate analysis showed a significant association between the occurrence of the injury and the event practiced by the athletes (-p-value=0.003), their participation in a high-level regional/international championship (-p-value=0.046), and whether or not they take chronic medications (-p-value=0.032).

CONCLUSIONS: Unfortunately, musculoskeletal injuries are prevalent in our population. Future prospective studies in track and field are needed to identify groups of athletes at increased risk, in order to establish appropriate injury prevention strategies.

Demographic factors and colorectal cancer screening

Gintare Jakstaite¹, Neringa Burokiene¹, Virmantas Kvedaras²

¹Clinics of Internal Diseases, Family Medicine and Oncology, Faculty of Medicine, Vilnius University, Vilnius, Lithuania

²Department of Econometric Analysis, Faculty of Mathematics and Informatics, Vilnius University, Vilnius, Lithuania

BACKGROUND: To evaluate rate of colorectal cancer screening in relation to age and sex in Vilnius University Hospital Santariskiu Klinikos Family Medicine Center. Colorectal cancer screening is for patients who are 50-74 year old. IFOBT and if needed colonoscopy are performed.

METHODS: 530 health's histories were analyzed retrospectively. The participation in the colorectal cancer screening was assessed on July 2009 – September 2013. The impact of sex and age to this program's results was interpreted statistically. Sensitivity and specificity were calculated for this program.

RESULTS: In colorectal cancer screening program females participated more often than males (p =0,067). This research found that oldest patients (over 70 year old) had significantly lower participation rate (4.42e-07). Sensitivity was found 83% and specificity was 81%.

CONCLUSION: Although men have higher risk of colorectal cancer, females were more active in screening than males. Patients over 70 year old should be more involved in the program.

A Very Rare Association: Male Breast Cancer and Neurofibromatosis Type 1

Kamil Başköy¹, Seyid Ahmet Ay¹, Yusuf Haçerli², Yusuf Akyüz³, Ferhat Deniz¹, Arif Yöнем¹

¹Department of Endocrinology and Metabolism, Gulhane School of Medicine, Haydarpaşa Training Hospital, Istanbul, Turkey

²Department of Internal Medicine, Gulhane School of Medicine, Haydarpaşa Training Hospital, Istanbul, Turkey

³Department of Family Medicine, Gulhane Military Medical Academy, School of Medicine, Ankara, Turkey

INTRODUCTION: Breast cancer in men is a rare disease, accounting for less than 1% of all breast cancers.

Neurofibromatosis (NF) Type1 is an autosomal dominant disease caused by mutations in the NF gene and it is associated with many benign tumors (neurofibromas). The prevalence of certain malignancies is increased in these patients. Among these malignancies, breast carcinomas are quite rarely observed. We present here a very rare case of male NF Type1 and breast cancer association.

CASE: A 52-year-old male patient with a history of NF type1 presented with a painful swelling in his right breast for 2 weeks. He had bilateral gynecomastia. Breast ultrasonography showed that there were some areas, which were compatible with the fibroglandular tissues, measuring 42x7mm on the right breast periareolar area and 39x7mm on the left breast periareolar area. Milimetric cystic openings and focal ductal dilatations in the lower outer quadrant of the right breast were observed as well. Complete blood count, routine biochemistry and hormones panel were all in normal ranges. Pathologic examination of excisional right breast biopsy was reported as “right breast invasive ductal carcinoma”. Modified radical mastectomy and axillary lymph node dissection were performed. Tumor was reported as “invasive ductal carcinoma grade II”. Immunohistochemical staining showed that nuclear estrogen receptor protein and nuclear progesterone receptor protein expression was strongly positive. Patient was referred to medical oncology clinic for evaluation for chemotherapy-radiotherapy.

CONCLUSION: Breast cancer and its association with NF1 is rare. We believe that germline mutations may play a role for the combination of NF1 and BRCA1/2. Here we present this case due to the fact that NF1 is quite a rare disease and this was the first case ever to be seen with the combination of NF1 and male breast cancer in our country.

P-1346

Botulism. A rare but life-threatening and emergency disease. A case report

Maria Bakola, Olga Igropoulou, Maria Bolosi, Athanasios Margaritis, Urania Mousafiri, Konstantinos Milios
Intensive Care Unit, General Hospital of Ioannina „G.Hatzikosta“, Ioannina, Greece

Background & AIM: Botulism is a rare but serious paralytic illness which is caused by a nerve toxin that is produced by *Clostridium botulinum* a spore forming, anaerobic bacterium that can contaminate commercially and home canned foods. The aim of this case is to remind family physicians and primary care providers of a rare and life-threatening disease, as well as to highlight the problems arising for the confirmation of the disease and the antitoxin administration.

METHOD: A 21 year old man, came to the emergency room with symptoms of dysphonia, dysarthria and dysphagia, 12- 18 hours after he had consumed canned foods.

RESULTS: The clinical examination revealed no fever, good level of consciousness, very good motility of the legs and pathological findings from the respiratory and the cardiovascular system. Computed tomography, magnetic resonance imaging and lumbar puncture were negative. The next few hours there was a gradual worsening of the previous symptoms, and new symptoms such as ophthalmoplegia (paralysis or weakness of the eye muscles), mydriasis and blepharoptosis (dropping of the upper eyelid) were developed. The aforementioned symptoms and a careful history established a diagnosis of botulism. The patient was intubated, transferred to the Intensive Care Unit and put on a mechanical ventilator for respiratory support. Purified IgG, cortisol and pyridostigmine was administered and Botulinum Antitoxin was ordered. After the sedation cessation, tetraparesis (weakness of all four limbs) and paralytic ileus were observed. Communication with him was done by moving the fingers of his right foot. Everyday rehabilitation helped him to have a slowly progressing and stable recovery.

CONCLUSIONS: Although the disease is very rare, family physicians and primary care providers should obtain a thorough history and always have in mind the symptomatology of this disease, because time is life!

Bad smell, bad life... Halitosis Approach in Primary Health Care

Carla Pina¹, Célia Mata², Fernando Charrão³

¹USF Cuidar, ACeS EDV I, Santa Maria da Feira, Portugal

²USF Santiago, ACeS Pinhal Litoral, Leiria, Portugal

³USF Esposende Norte, ACeS Cávado III, Esposende, Portugal

Introduction and Aim

Halitosis is a common health problem with psychological, social and economic impact. The General Practitioner (GP) should be alert to this problem and be aware of its causes and consequences on the patient's life quality. This study aims to review the available evidence on the diagnosis and therapeutic management of halitosis by GP.

Methods

This work is a classical literature review employing the Mesh term "halitosis", "primary care" and "adults" and using textbooks, review articles published in major databases and standards of clinical guidance of national and international societies.

Results

Studies indicate that a moderate halitosis occurs in approximately 25% of the population worldwide. The pathophysiological mechanism is still poorly understood. There are systemic and local conditions associated with oral cavity problems in the source of halitosis. However, in its etiology more serious, but less frequent, underlying causes such as otorhinolaryngological, respiratory and gastrointestinal diseases, as well as renal and liver impairment or metabolic syndromes may occur.

Conclusion

Significant costs are associated with the diagnosis and treatment of halitosis, including specialist evaluation and diagnostic tests. These costs would be minimized by the primary health care adopting an evidence based anamnesis and appropriate referral justified by clinical suspicion.

The role of the GP in the presence of a patient with halitosis should go beyond the underlying cause and it is important to understand and appreciate its psychosocial implications.

Keywords: halitosis, primary care, adults

Table 1. The etiology of halitosis

PERIODONTAL INFLAMMATION	Microorganisms and inflammatory products present in gingivitis/periodontitis are capable of producing odoriferous substances.
TONGUE COATING	Tongue coating including bacteria, desquamated cells and saliva, among others, is one of the important etiological factors of halitosis.
MICROBIOLOGY	Bacteria in saliva, soft and hard tissues produce odoriferous substances in vitro.
NON-ORAL CAUSES OF HALITOSIS	Ear-nose-throat problems such as tonsillitis, sinusitis, the presence of strange body material and rhinitis were frequently associated with non-oral halitosis. The gastro-intestinal tract can only indirectly (haematogenic) influence bad breath. A majority of patients and physicians still abusively believes that halitosis originates from the stomach. The latter is only correct in 0.5% of the cases. Stressful situations also might contribute to increased halitosis. Halitophobia is a paradoxical situation that affects 15% of patients referring halitosis symptoms. Psychogenic cause has an important impact in patients life quality due to obsessive idea of a bad breath. Rare causes: metabolic disorders, hepatic and endocrine situations.
MEDICATION	Some medications result in a dry mouth; recently was verified that the use of bisphosphonates can contribute to oral malodour.

Table 2. The treatment of halitosis

Table 2. The treatment of halitosis	
PERIODONTAL THERAPY	Periodontal treatment decreases halitosis.
APPROACHES DIRECTED TO TONGUE COATING	Several studies have demonstrated that reducing bacteria on the dorsum of the tongue will diminish halitosis.
ANTIMICROBIALS	Since the presence of microorganisms from oral biofilms is responsible for producing malodor, any type of treatment approach that has impact in the oral microbiota has the potential of reducing halitosis.
MEDICAL APPROACHES	If oral approaches are not successful in reducing/eliminating halitosis, patients should be referred to a physician. If the medical causes cannot be suspected, the first professional to be referred is the otorhinolaryngologist, followed by the gastroenterologist. If halitophobia is considered, a psychologist or psychiatrist should be included.
MASKING AGENTS	The use of chewing gum may decrease halitosis, especially through increasing salivary secretion. Mouthrinses containing chlorine dioxide and zinc salts have a substantial effect in masking halitosis, not allowing the volatilization of the unpleasant odor.

Integration of information in our Medicine consultation of Family, with regard to a case of Syndrome of Good

Samuel García Moreno, Carmen María Jimenez Herrera, Sandra Roldan García

Centro de Salud Nuestra Señora de La Oliva. Alcalá de Guadaira. Sevilla.

REASON FOR CONSULTATION: Patient 75 years old, male, who consults by fever.

PERSONAL ANTECEDENTS: Chronic diarrhea, months of evolution followed by private doctor, who was diagnosed with recurrent intestinal giardiasis. Respiratory infections of repetition.

PRESENT DISEASE: Intermittent fever of three days of evolution, cough, expectoration whitish and difficulty to breathe. He refers anorexia, asthenia and he tells us a loss of 37 kg during the last year, which was attributed to his chronic diarrhea and anorexia. Before the clinic started constitutional study box.

COMPLEMENTARY EXPLORATION AND TESTS:

Good general condition. Great thinness, without cachexia.

Pulmonary Auscultation: abundant mucus of upper respiratory tract, vesicular murmur preserved.

Abdominal exploration, digital rectal examination, exploration normal neurological.

Hemogram, coagulation and biochemistry, analytical thyroid, normal antinuclear antibodies and anticeliac quía. Negative lactose curve. Serology of infectious diseases normal.

Stool culture positive for G.lambdia.

Urine cultures and negative blood cultures.. Culture of sample obtained with bronchoscopy: E.coli.

Proteinogramme: severe hypogammaglobulinemia of all the immunoglobulins, especially the immunoglobulin G.

Normal Endoscopy. Gastroduodenal transit demonstrated malabsorption.

TAC: injury in anterior mediastinum compatible with thymoma, without lymph node involvement, and bronchiectasis.

CLINICAL TRIAL:

- Syndrome of Good (humoral immunodeficiency associated with thymoma)
- Chronic diarrhea (malabsorption, malnutrition severe, recurrent infections)
- Respiratory Infection by E.coli.

DIFFERENTIAL DIAGNOSIS:

- Síndromes of malabsorption, celiac disease.
- Taking of anorexígenos, alcoholism, diabetes or hyperthyroidism
- Autoimmune diseases.
- Neoplasms.
- H.I.V.

TREATMENT:

Immunoglobulins for the treatment of humoral immunodeficiency and antibiotic therapy for the treatment of

chronic diarrhea.

FINAL COMMENT

Good syndrome is a rare disorder that treatable associated humoral immunodeficiency and thymoma (benign) without known etiological relationship. It is associated with repeat infections and chronic diarrhea due to the humoral immunodeficiency.. This case shows the importance of the comprehensive approach to a patient as well as the overall vision of the symptoms to reach the correct diagnosis.

Keywords: Syndrome of Good, thymoma, diarrhea

TAC

TAC: thymoma, without lymph node involvement, and bronchiectasis.

⁵Centro de Salud La Almozara, Zaragoza II, España

⁶Centro de Salud José Aguado, León, España

BACKGROUND@AIM:

17year-old-woman without allergies and previous diseases, referred history of 6months characterized by anorexia, weight loss of 5Kg and arthralgias. She recounted fever, rhinorrhea and oral ulcers the previous week. Primary care physician requested urgent blood test and thorax Xray, revealing bilateral infiltrates, hilar adenopathies, elevated acute phase reactants (VSG, PCR), leukocytosis and thrombocytosis. She was admitted to Internal Medicine for further study.

METHOD:

-Physical examination: Blood Pressure 108/68, Heart Rate 102, Oxygen Saturation 93%, FR 20. Cardiopulmonary auscultation: Tachycardia, regular rhythm without audible murmurs; decreased vesicular murmur in both bases.
-Blood test: leukocytes 14500/mm³; Platelets 452000/mm³; Hemoglobin 10,6g/dl; PCR 56; VSG 520; PR3-ANCA: positive; serum creatinine 1,9mg/dL, serum urea 47mg/dL. ANA, C3, C4, Cryoglobulins, hepatic and HIV serology, liver function: negative.
-Urinalysis: microscopic hematuria and proteinuria.

- ThoraxX Ray:diffuse opacities,fleeting bilateral pulmonary infiltrates,hilar adenopathies.
- Thoracic Scanner:nodules in bases of both lungs,signs of cavitation,stenotic lesions. Bilateral pleural effusions.
- Skin Biopsy: nonspecific leukocytoclastic vasculitis(no complement and immunoglobulin on immunofluorescence).
- Transbronchial Lung Biopsy:granulomatous inflammation.
- Kidney Biopsy:pending.

RESULTS:

Given symptoms and results of additional testing, patient was diagnosed with Wegener Granulomatosis(small vessel vasculitis).Patient meet several clinical criteria:nasal and oral inflammation,abnormal chest radiograph and urinary sediment,granulomatous inflammation on biopsy of perivascular area.

Being hospitalized presented self-limited hemoptysis,dyspnea,and pericarditis.She also presented purpura in lower extremities without necrosis or ulceration.

She was treated with high doses of ciclophosphamide and prednisone,with good therapeutic response.

CONCLUSIONS:

Wegener's Granulomatosis consists of granulomatosis with polyangiitis.It occurs in older adults (reported at all ages).Both genders are affected.More common among white individuals.

Patients present with constitutional symptoms which may last for months without specific organ involvement.Several organs may be affected(ear,throat,nose,lung,kidney, skin,eyes,nervous system,gastrointestinal and lower genitourinary tract,heart,parotid glands,thyroid and liver).

Prompt diagnosis is important to initiate therapy that may be life saving and organ sparing.This may be difficult since presenting symptoms are hard to distinguish from those of non-vasculitic processes(infection or malignancy).Positive ANCA strongly suggests vasculitis.Histologic examination of affected organ is required for definitive diagnosis.

It's important for primary care physicians high index of suspicion to avoid missing this disease,when attending patients with multisystem symptoms.

Patients Satisfaction for Social Security Administration in Community Health Center of Manado City

Henry Palandeng, Iyone Siagian, Feicy Gaghana

Department of Community Medicine, Faculty of Medicine, Sam Ratulangi University, Manado, Indonesia

Introduction

The government of Indonesia is trying to provide healthcare for all the people by social security administration known as Badan Penyelenggara Jaminan Sosial (BPJS) and Manado city is one of the cities which has to be in line with the government to organize the program. BPJS Program is devoted to the public good for Manado Citizens in order to have the right to receive healthcare and improve community health status in Manado.

Patient satisfaction provides information whether the healthcare that provided by the community health center is satisfied for its use. The purpose of this research is to determine level of patient's satisfaction for health care in Tuminting community health center.

Methods

Descriptive research. Sample size using purposive sampling technique is 106 patients. Questionnaires used to interview respondents. We asked five dimension of quality of services which are; reliability, responsiveness, assurance, empathy, tangibles and patient overall satisfaction. To measure respondents' satisfaction assessment services given the Likert's scale is considered suitable.

Results

The results shows 50,9% patients satisfied with reliability, 54,7% patients satisfied with responsiveness, 77,4% patients satisfied with assurance, 55,7% patients satisfied with empathy, And 66% patients satisfied with tangible. The overall patient satisfaction rate for healthcare is 51,9%.

Conclusions

The health care given by Tuminting community health center to patients goes along with the order that satisfies patient the most is assurance, tangibles, empathy, responsiveness, and reliability.

1. Patient registration system needs to be improved.
2. Physicians need to pay more attention to the provision of information about the diseases and patient's explanation. Nurses should also be more friendly and polite.
3. Administrators need to optimize their duties and functions.
4. The attention given by health professionals to patients needs to be improved further.
5. More attention to the cleanliness of the reception area and the surrounding environment

The Importance of Calcitonin Measurement in Thyroid Nodules: A Case of Medullary Thyroid Cancer With Benign Fine Needle Aspiration Biopsy But Elevated Serum Calcitonin

Seyid Ahmet Ay¹, Kamil Başköy¹, Yusuf Hançerli², Yusuf Akyüz³, Ferhat Deniz¹, Arif Yönel¹

¹Department of Endocrinology and Metabolism, Gulhane School of Medicine, Haydarpaşa Training Hospital, Istanbul, Turkey

²Department of Internal Medicine, Gulhane School of Medicine, Haydarpaşa Training Hospital, Istanbul, Turkey

³Department of Family Medicine, Gulhane Military Medical Academy, School of Medicine, Ankara, Turkey

INTRODUCTION: The prevalence of thyroid nodules detected by imaging methods is around 20-76%. When thyroid nodules are detected, echogenicity, presence of calcification, size of nodule, and Doppler blood-flow patterns should be evaluated thoroughly in terms of malignancy potential and, if necessary, thyroid fine needle aspiration biopsy (FNAB) should be performed as well. In addition, if the nodule is detected in a patient for the first time, calcitonin level should be checked in order to confirm or rule out the medullary thyroid cancer (MTC). MTC, a rare cancer constituting 4% of thyroid tumors, originates from calcitonin-secreting parafollicular C cells. About 75% of MTCs are sporadic while the remaining 25% of MTCs are hereditary. RET proto-oncogene is responsible for the genetic transition of the disease. We present here a case of MTC previously had a benign FNAB report, but later, with the finding of increased serum calcitonin, repeat biopsy revealed MTC.

CASE: A 49-year-old female patient was referred to endocrinology clinic after incidental thyroid nodule detection by neck ultrasound (US). Thyroid US revealed a solitary hypoechoic nodule, measuring 4x2 cm in the right inferior lobe extending into the retrosternal region. Her thyroid function tests were normal. FNAB of the nodule was reported as benign cytology. Since it was the first nodule evaluation for the patient, calcitonin levels were checked as well and were found to be 28000 pg/ml (reference: 0-5 pg/ml). Her repeated calcitonin, as well as CEA level, was found to be increased. MTC was strongly suspected and repeat FNAB revealed malignancy. RET gene mutation analysis was positive. Screening for hyperparathyroidism and pheochromocytoma showed no related abnormality. Patient was screened for metastasis due to the fact that her calcitonin level was above 500. Metastases were observed in the mediastinum and lumbar spine by computerized tomography. Patient was considered as stage 4 MTC, total thyroidectomy and then radiation therapy was scheduled.

CONCLUSION: We want to emphasize here with this case, how important and necessary it is to check calcitonin levels at least once, regardless of the size of the thyroid nodules or FNAB results.

Keywords: Thyroid nodule; Medullary Thyroid Cancer; Calcitonin

Efficacy of ultrasound therapy with Fastum gel on patients with gonarthrosis

Žani Banjanin¹, Ljubomir Šormaz¹, Jadranka Pešević Pajčin¹, Radmila Ubović², Brankica Galić³

¹Health centre "Dr Mladen Stojanović", Laktaši, Bosnia and Herzegovina

²Institute of Occupational Medicine and Sports Republic of Srpska, Banja Luka

³Health centre, Prijedor, Bosnia and Herzegovina

OBJECTIVE: Osteoarthritis is a degenerative joint disease, characterized by progressive destruction of articular cartilage. The main clinical manifestation is pain and progressive functional disability.

The aim of this study was to examine the effectiveness by applying Fastum gel (ketoprofen) in patients with gonarthrosis

METHOD: We examined 60 patients, aged 50-83, with clinical-radiological diagnosis of knee OA. Fastum gel was applied by phonophoresis to 30 patients. To the remaining 30 patients, a neutral contact gel was applied. Application was performed 2 times a day for 14 days. Ultrasound intensity was 1.0 W/cm². Besides phonophoresis, all examinees had kinezotherapy. We used the WOMAC Osteoarthritis Index to compare the results between two analysed groups. All subjects were asked to fill out the questionnaire at the beginning and at the end of the therapy.

RESULTS: After 14 days of application of Fastum gel, Womac subskor for pain decreased by 22.03%, functional capacity subscore decreased by 6,50%, and subskor for stiffness decreased by 25.27%. In patients treated with a neutral gel, after 14 days, Womac subskor for pain decreased by 3.69%, subskor for reduced functional ability decreased by 1.18%, and subskor for stiffness decreased by 14.12%.

CONCLUSION: There was a significant improvement of functional capacity, reduced stiffness and pain in the knees after the ultrasound treatment of Fastum gel in patients with knee OA.

Keywords: Gonarthrosis, Fastum gel, WOMAC OA index.

Basic demographic characteristics and classification of OA

	Fastum gel	Neutral gel	Total
Number of respondents	30	30	60
Demographics			
Age (SD)	69.1±7.9	66.6±8.6	67.85±8.3
Gender (%)			
Men	10 (33.3%)	13 (43.3%)	23 (38.3%)
Women	20 (66.7%)	17 (56.7%)	37 (61.7%)
Classification of OA according to Kellgren-Lawrence scale			
Level II	19 (63.3%)	16 (53.3%)	35 (58.3%)
Level III	11 (36.7%)	14 (46.7%)	25 (41.7%)

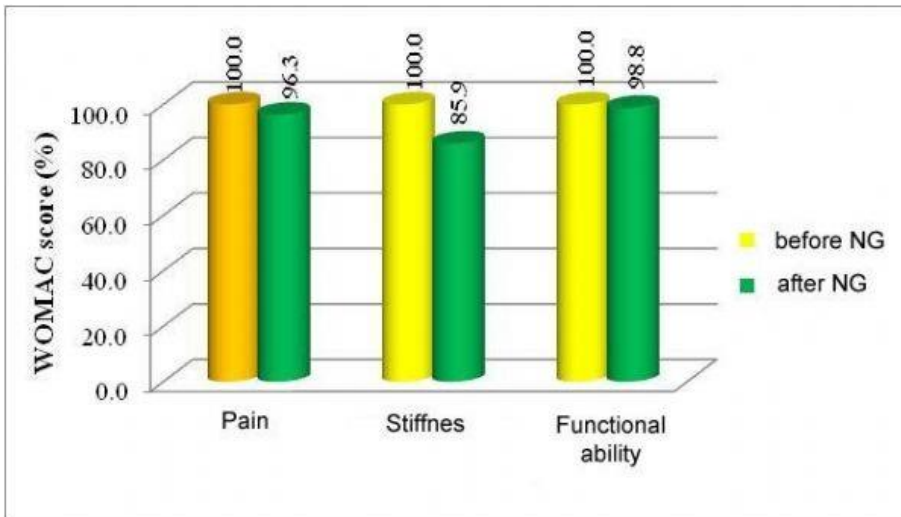

The study included 60 patients with an average age of 67.85 years. 30 patients were treated with a neutral gel and 30 with Fastum gel. Significant differences for the observed size before treatment between the groups were found for age and gender. The representation of patients with varying degrees of OA was very similar in both groups.

Analysis of differences WOMAC score before and after therapy

WOMAC index	Pain	Stiffness	Functional ability
Fastum gel group			
WOMAC score before treatment	13.5±3.3	6.1±1.3	42.6±13.6
WOMAC score after treatment	10.5±3.9	4.5±1.2	39.8±14.0
T-value	5.24	4.74	5.32
p-value	p<0.01	p<0.01	p<0.01
Neutral gel group			
WOMAC score before treatment	13.5±3.2	5.9±1.3	42.4±13.4
WOMAC score after treatment	13.0±3.2	5.1±1.5	41.9±13.2
T-value	2.19	3.15	2.29
p-value	p<0.05	p<0,01	p<0,05

After applying Fastum gel was statistically highly significant improvement in functional abilities of the subjects, a reduction in pain and stiffness (p <0.01). Improving functional ability and reducing pain in subjects which we applied a neutral gel was statistically significant (p <0.05) and decrease stiffness was statistically highly significant (p <0.01).

WOMAC subskor before and after ultrasound treatment with a neutral gel (NG)

In patients treated with neutral gel, after 14 days, subscore WOMAC pain was lowered to 3.69%, subscore for functional capacity was lowered to 1.18% and subscore for stiffness for 14.12%

WOMAC subscore before and after ultrasound treatment with Fastum gel (FG)

After 14 days of application Fastum gel subscore WOMAC pain decreased by 22.3%, subscore for functional capacity was lowered to 6.50%; and subscore for stiffness for 25.27%.

Synkinesia And Hemifacial Spasm Developed After Bell's Palsy: A Case Report

Esra Meltem Koç¹, Ali Murat Koç², Duygu Ayhan Başer³, Rabia Kahveci⁴

¹Department of Health Technology Assessment, Ministry of Health, Ankara, Turkey

²Department of Radiology, Gazi University, Ankara, Turkey

³Directorate of Public Health, Kocaeli, Turkey

⁴Department of Family Medicine, Ankara Numune Training and Research Hospital, Ankara, Turkey

INTRODUCTION: Bell's palsy is an acute started, limited time continued palsy with unclear etiology. It seems 1/60 risks and 11-40/100,000 per years incidence throughout their lives.

CASE: A 26-year-old female patient was admitted to our hospital with complaints of decrease of the right eye and right shift of mouth, facial swelling on the right half and mild numbness and weakness. There was idiopathic facial paralysis history at the right eye about a year ago. We detected ptosis at the right eyelid and edema at the right half of face at our physical examination and we started antiviral and oral prednisone 1mg/kg/day treatment with thinking recurrent the right facial nerve paralysis in patient. At our control examination 10 days after patient said there was no reduction at her complaints by using therapy and complaints in the form of spasms get started at right half of the face and learned that watery eyes tearing, a right frotoorbital headache get started. On top of that the patient was referred to the Ear Nose Throat-ENT-Diseases. ENT did not think peripheric facial paralysis in patients; suggested to investigate the etiology of ptosis. Patient was referred to neurology. Routine laboratory studies and serological tests were within normal limits. Temporal MR and MR sistenograf examinations normal. Patient evaluated with EMG. Nerve damage secondary to previous facial paralysis was thought. Carbamazepin started for hemifacial spasm and synkinesia. Botulinum Toxin A injection started due to complaints were continuing after 1 month therapy. By this therapy complaints of patient were reduced. Patient continuing her treatment with 3-6 months periods.

DISCUSSION: Improvement in the facial nerve paralysis is expected up to one year. Spontaneously and full recovery was observed in approximately 80-85% of patients within the first three months, while 15-20% lighter, 5% may be serious nerve damage. Synkinesia and facial spasms in partially improved facial nerve paralysis can be treated successfully with the subcutaneously or intramuscularly applied botulinum toxin.

charles bonnet's syndrome: a case presentation

Sema Erdogmus¹, Osman Aga Onal², Aylin Ardagil Akcakaya³, Hasan Huseyin Mutlu¹, Zuhal Aydan Saglam¹

¹Family Medicine, istanbul medeniyet university goztepe training and research hospital, istanbul, turkey

²Department of Psychiatry, istanbul medeniyet university goztepe training and research hospital, istanbul, turkey

³Department of Ophthalmology, istanbul medeniyet university goztepe training and research hospital, istanbul, turkey

INTRODUCTION: Charles Bonnet's syndrome(CBS) is rare disease which is characterized with vision loss,visual hallucination and preservation of cognitive status following ocular pathology.

CASE: H.B aged 91,has 2 children,literate and living with daughter was operated 3 years ago due to globe rupture in her left eye.Phthisis bulbi occurred subsequently in left eye and visual acuity level was reported as p+(can only recognize light).However,2 years after this case,following the occurrence of secondary choroidal neovascular membrane over macular degeneration.While on May 2014,due to preretinal bleeding in the right eye,visual acuityit declined to counting fingers from 1 meter which was 18 letters/4 meter.Patient was referred to psychiatry department when she reported visualizing/seeing imaginary colorful images bilaterally–mostly in front of her right eye.During psychiatric evaluation,she was conscious,cooperation was sufficient and tendency was normal.Her cognitive function was sufficient,psychomotor activity was normal.Affection was depressive,perception was shallow,while content and flow of thought was normal.She was suffering from a pain covering of her body and was scared of becoming blind and death.She had been getting psychiatric drugs since her husband died and was still under duloxetine and -if required- alprazolam.When she first started complaining 6 months ago she stated that she saw colorful lines and transitions,but on following day she began to see a forest,moving objects and objects without actual colors.It was observed that visual hallucinations of the patient was simple at first but by time it got complex.Surprisingly,she was aware of the fact that she was experiencing hallucinations.She was diagnosed as CBS and mirtazapine was added for treatment of sleep disorder and anxiety.At the next appointment,hallucinations,distress,fear and concern were decreased.

DISCUSSION: Macular degeneration,glaucoma,cataract and decollement are mostly seen concurrently CBS.Patients become anxious when hallucinations start,our patient stated that she was happy with colorful hallucinations.With this case presentation,we aimed to report a rare syndrome presenting with sensual loss at an old woman.

Keywords: charles bonnet's syndrome, visual halusination, macular degeneration, preservation of cognitive status

Eugene "Gene" Garfield was born in September 16, 1925 in New York City, New York, United States. He is a world-wide known American scientist. He is also one of the founders of bibliometrics and scientometrics, an art lover, a multilinguist, an entrepreneur, a musician and a prolific author. Garfield, who graduated from Department of Chemistry at Columbia University in 1949 and received his M.S. Library Science in 1954 and his Ph.D. degree in Structural Linguistics at the University of Pennsylvania in 1961, is mostly known around the world for ISI. Thanks to ISI, created by Garfield, researchers from all disciplines have been benefiting from a more systematic, faster, objective, interdisciplinary and extensive system while carrying out their researches and this index has enabled them to track down the origins of a scientific idea and led to creation of other information retrieval algorithms.

Determination Of The Knowledge Levels, Attitudes, And Behaviors Of Islamic Religious Officials Toward Blood Donation

Hamit Sırrı Keten¹, Oğuz Işık², Celal Kuş², Özgür Ersoy³, Soner Ölmez⁴, Fatiş Yıldırım², Mustafa Çelik²

¹Department of Family Medicine, Kurtul Family Health Center, Kahramanmaraş, Turkey

²Department of Family Medicine, Medical Faculty, Kahramanmaraş Sutcu Imam University, Kahramanmaraş, Turkey

³Department of Public Health, Medical Faculty, Cukurova University, Adana, Turkey

⁴Department of Family Medicine, Samsat Family Health Center, Adıyaman, Turkey

BACKGROUND: The aim of the present study was to determine knowledge level, attitudes, and behaviors of Islamic religious officials toward blood donation.

METHOD: This study included 334 religious officials rendering service in the province of Kahramanmaraş, located in the Mediterranean region of Turkey. A questionnaire was administered to gather sociodemographic data of the participants and their knowledge levels, attitudes, and behaviors toward blood donation. The questionnaire consisted of 11 questions that yielded a total of 11 points.

RESULTS: The religious officials in the study included 206 imams (61.7%, males) and 128 Quran course instructors (38.3%, females). Of study participants, 134 (40.1%) reported a previous experience of blood donation and 200 (59.9%) denied previous experience of blood donation. The mean knowledge score was 7.09 ± 2.54 points for males and 6.89 ± 2.18 points for females. Male and female participants achieved comparable scores ($p=0.476$). Of the participants, 291 (87.1%) agreed and nine (2.7%) disagreed with the expression, "Blood donation is permissible in Islam;" 34 (10.2%) participants had no idea. Of the participants, 303 (90.7%) agreed and 12 (3.6%) disagreed with the expression, "Blood donation important for one's survival;" 19 (5.7%) participants had no idea.

CONCLUSIONS: The present study revealed considerable deficiencies in knowledge about blood donation among religious officials. In addition, the rate of blood donation and willingness to donate blood were low among religious officials. Although the level of knowledge about blood donation was similar in males and females, it was an interesting finding that the blood donation rate was significantly higher in males than in females. A high proportion of religious officials deemed blood donation permissible in Islam.

²Department of Clinical Microbiology and Infectious Diseases, Necip Fazil City Hospital, Kahramanmaraş, Turkey

³Department of Family Medicine, Medical Faculty, Kahramanmaraş Sutcu Imam University, Kahramanmaraş, Turkey

⁴Department of Emergency Medicine, Medical Faculty, Kahramanmaraş Sutcu Imam University, Kahramanmaraş, Turkey

BACKGROUND: The aim of this study was to determine the prevalence of Candida carriage and Candida species among cigarette and Maras powder (MP) users.

METHOD: This study was conducted on 180 volunteering men in 20 cafes in the city of Kahramanmaraş, Turkey. The sociodemographic characteristics of the participants and the behaviors of MP and cigarette usage were noted down. Culture specimens were obtained from bilateral buccal mucosa and dorsum of the tongue with a sterile cotton-tipped swap.

RESULTS: The specimens were inoculated into Sabouraud Dextrose Agar. The mean age of the participants was

40.49 ± 12.89 years (min = 18, max = 87). Fifty-eight percent of the cigarette users, 56.7 % of the MP users, and 36.7 % of the control group were Candida carriers. The difference of Candida carriage between cigarette and MP users and the control group was statistically significant (P = 0.018 and P=0.029 respectively). The prevalence of Candida carriage was similar between cigarette and MP users (P=0.854). The most frequently isolated species was Candida albicans at a rate of 30 % in the cigarette users' group, 28.3% in the MP users' group and at a rate of 18.3% in the controls. The prevalence of Candida tropicalis carriage was found to be at a rate of 20% in cigarette and 21.7% in the MP users' group compared to 11.7% in the nonusers.

CONCLUSIONS: In the present study we found that the prevalence of oral Candida carriage was significantly higher among cigarette and MP users.

P-1358

Temporomandibular Joint Pain – Diagnostic challenges

Angela Amorim

USF Santa Maria, Tomar, Portugal

Background and AIM:

Rheumatoid arthritis (RA) is an autoimmune disorder characterized by joint inflammation, erosive properties and symmetric multiple joint involvement. Temporomandibular joint (TMJ) arthritis is frequent in patients with RA, but is seldom the first joint affected. This case consists of a female with undiagnosed RA who first presented with signs and symptoms in the TMJs. It highlights the importance of professional awareness of such occurrences.

METHOD:

Data was collected during office visits with patient; analysis was made of patient's clinical records including medical history, physical examination, diagnostic procedures, treatment and evolution. A review of literature regarding TMJ arthritis was performed.

RESULTS:

19-year-old female patient visited Family Physician (FP) complaining of bilateral TMJ pain over 2 months. On eliciting the history, patient had pain during jaw movement and limitation of maximal mouth opening. Clinical examination revealed bilateral tenderness on TMJ palpation and limited TMJ range of motion. No joint sounds or tenderness on masticatory muscle palpation were identified. TMJ tomography images revealed erosion of cortical bone of both condyles, with apparent partial erosive amputation, relative bone sclerosis of the posterior joint eminence. Blood analysis revealed slight anemia, elevated C-reactive protein and sedimentation rate. Referred to maxillofacial surgery and later to autoimmune diseases consult where the diagnosis of RA was made. Medicated with methotrexate and prescribed physical therapy and speech therapy in an attempt to recover TMJ movements. Due to great distance of patients' residence to hospital, it was suggested that the FP collaborate in future care.

CONCLUSION:

General practitioners are constantly faced with common signs and symptoms of an apparently benign nature that may be in reality the initial presentation of more complicated conditions. Therefore a holistic approach to the patient is imperative, including an accurate clinical history and clinical examination, complemented by appropriate auxiliary diagnostic tests.

Keywords: arthritis, temporomandibular joint, autoimmune

P-1359

A Case of Nicotine Addiction due to Smokeless Tobacco Use for Hemorrhoids

Mustafa Haki Sucakli, Yasar Kosar

Department of Family Medicine, Kahramanmaras Sutcuimam University, Medical Faculty, Kahramanmaras, Turkey.

Introduction

Maras powder, a kind of smokeless tobacco, is composed of leaves of a plant called *Nicotina Rustica* Linn, grown in the East Mediterranean region of Turkey and called "madness" by local people. It is known that tobacco has been used to treat various diseases. In this report, a case of nicotine addiction due to Maras powder use for the treatment of hemorrhoids will be presented.

Case

A 54-year-old woman presented to our outpatient clinic for the treatment of Maras powder addiction. She had been using Maras powder for 24 years. She first used Maras powder to stop her rectal bleeding and pain due to hemorrhoids when her sister suggested using it 25 years ago. She reported that the powder relieved her pain and stopped her bleeding for a while, but that her complaints recurred later. The patient, who had not told any doctors about her 24-year history of Maras powder use, admitted her habit when she presented to our outpatient clinic. When she told to use a packet of the powder every day, she was admitted to the outpatient clinic for the treatment of her addiction.

Familial history showed no pathological conditions. History and physical examination revealed nicotine addiction and stage two internal hemorrhoids.

Discussion and Conclusion

The patient reported here also used a kind of tobacco, i.e. Maras powder, to treat her hemorrhoids and she benefited from vasoconstrictor effects of nicotine and relieved her symptoms. However, she became a nicotine addict. Family physicians should adopt a biopsychosocial approach to achieve an effective therapy of tobacco addiction. They should create an appropriate environment which will allow them to diagnose and treat similar cases to the one presented here. They should also help society to become aware that nicotine products cannot treat any diseases.

Keywords: Maras powder (Smokeless Tobacco), nicotine, family physicians

Relationship Between Social Tendencies And Depression Scores In Age Of 11-17 Adolescent

Elif Cirit, Ismail Arslan, Nuri Şengüleroğlu, Oğuz Tekin

Department of Family Medicine, Ankara Training and Research Hospital, Ankara, Turkey

Background & AIM: Adolescence is a period that remarkable biological, psychological and social changes happen. In the socialization process, adolescents adapt with many situations to reach the adult model. This adaptation is established with family, friends, schoolmates and other people. One of the most difficult development task in adolescence is related to social consistency. We aimed to investigate the relationship between social tendencies of adolescents and depression scores in the 11-17 age range in our study.

METHOD: In our study, 280 adolescents, were included who admitted to family medicine department of Ankara Training and Research Hospital on 01 September to 30 November 2014. Participants filled informed consent form. Fatih-Scale of Social Tendencies-Adult version and Depression Scale for Children were performed to adolescents.

RESULTS: The participants were 111 men and 169 women. The average age was 15 ± 2 years for men and 15.3 ± 1.8 years for women. Three factors of Fatih-Scale of Social Tendencies-Adult version (Social adaptation & status $p=0.29$, avoiding of violence $p=0.02$, aims & ideas $p=0.23$) were significantly higher in women. Negative correlation was detected between childhood depression scale scores and Fatih-Scale of Social Tendencies-Adult version scores. (social adaptation&status $N=280$ $r=-0.387$ $p<0.001$, avoiding of substance $N=280$ $r=-0.335$ $p<0.001$,

avoiding of violence N=280 $r=-0.399$ $p<0.001$, school status N=280 $r=-0.490$ $p<0.001$, family status N=280 $r=-0.491$ $p<0.001$, aims & ideas N=280 $r=-0.330$ $p<0.001$)

CONCLUSIONS: Social consistency scores were higher in women and this may suggests that male gender is a risk factor for social consistency. Increased depression scores were observed with decreased social consistency. For this reason, it is really important to early diagnose and treat depression; and likewise depression is a considerable diagnosis for adolescents who have lower social consistency.

Scale Adjustment for the Examination of the Relationship between the Emotional State of an Individual and Having a Pet

Kürşad Akkaya, Dilek Güldal

Department of Family Medicine, Dokuz Eylül University, Izmir, Turkey

Throughout the history, pets played an important role in human life. Even though domestic and friendly animals exist in people's lives for a long time, thoughts on pets' effect on human health have come about only recently. In the studies of treatments with animal support, the benefits of interaction with friendly, trained and well-groomed animals are shown. Despite the contradictory results, it was observed that people who have dogs have better health than people who don't due to walks they have with their dogs. The objective of this study was to find out the validity and reliability of the Poresky's "companion animal bonding scale" in Turkish language.

METHOD: In this methodological study, translation and a re-translation was performed. The data was analyzed in SPSS 15 program. In order to measure the external validity, Lexington Attachment to Pets scale was used. Reliability and validity in Turkish language of latter scale was done by Hacer Karameşe. For measuring reliability, split half and cronbach alpha analyses were used.

RESULTS: In order to measure the scale validity and reliability our survey was applied to 46 pet owners. For external validity, the correlation analysis between two scales was done and the Pearson correlation value was found to be -0.568. The reason of the negative result was because in one of the scales the dependence increases as the points increase but in the other one dependence decreases as the points increase. Regarding reliability tests; the Split half Spearman-Brown value was 0.855 and the Cronbach alpha value was 0.818.

CONCLUSION: The companion animal bonding scale was concluded to be highly reliably and valid in Turkish.

Do Literacy Levels Effect Use of Primary Care in Adults with Acute Diseases?

Selami Doğan¹, Nuray Doğan², Erdiñç Yavuz³, Erol Yayla⁴, Raziye Şule Gümüştakım⁵

¹4th Family Healthcare Center Bayraklı İzmir Turkey

²Digor State Hospital Kars Turkey

³1st Family Healthcare Center Rize Turkey

⁴5th Family Healthcare Center Afyon Turkey

⁵Sarıselvililer State Hospital Karaman Turkey

Primary care in Turkey has undergone a substantial change since 2010 and now approximately 22.000 family physicians serve whole nation at 6.756 family health care centers. It was reported that use of healthcare systems was affected by patients' socioeconomic status, their previous experience related to health care, whether they have social security, distance to health care facilities, reputation of these facilities. In this study we aimed to investigate the effect of literacy on use of health care for acute illness which we considered that it may be better related with health perception of the individuals.

The study design was retrospective. Adults 18 years of age or older who admitted to Bayraklı Healthcare Center between 1.10.2010-1.1.2014 for acute reasons were included in the study. Patients with chronic diseases were excluded. WHO definition of chronic disease was used. Literacy levels of the study patients were divided into eight individual groups from illiterate to post-graduate and compared with the number of their and the number of drugs prescribed.

Mean age of the patients was 35,84 years; 55,5% of them were male and 44,5% of them were female. Majority of the patients were graduated from elementary school (54,6%). Only 6,8% of the patients had a university degree. The percentage of illiterate patients was 1,2%. Our results showed that as age increased frequency of admittance was also increased but this difference did not reach statistical significance ($p=0,388$). As age increased the number of drugs prescribed also increased ($p=0,0001$). Our results showed that as literacy levels declined the number of drugs prescribed increased and it was statistically significant between all literacy levels. The frequency of admittance also increased but this difference did not reach statistical significance ($p=0,150$).

P-1363

69th years old man with different diseases in relation with only one diagnose

Sandra Murgui Betran, Laia Gené Huguet, Amparo Hervas Docon
CAPSE, CAP Comte Borrell, Barcelona, Spain

CASE SCOPE:

Primary Health Care, Specialized Care and Emergency.

REASONS FOR CONSULTATION

The patient has had cough, fever and asthenia during some days; he was visited by his private pneumologist, in the Primary Health Center and in emergency room for several times. He did not improve despite the treatments recommended.

CLINICAL HISTORY

Individual approach

Personal BACKGROUND: Bronchial allergic asthma of 5 years of evolution, nasal severe polyposis during 10 years, and two vein profound thrombosis in the last year.

Anamnesis: 69th years old man affected for cough, fever, arthralgia and asthenia that need a lot of medical visits.

Physical exploration: Few pitting edemas, 37.6°C fever, anodyne the rest.

Complementary explorations: Chest radiography normal; urine test with proteins, hemoglobin and kappa light chains; test blood with rise PCR, VSG and eosinophils, monoclonal gammopathy with kappa IgG chains, rheumatoid factor positive, lupic anticoagulant positive, IgG anticardiolipine positive, IGM anticardiolipine negative; biopsy inform of nerve with necrotic vasculitis with fibrinoid necrosis affecting medium diameter vein, muscle with denervation phenomenon and re innervation; electromyogram inform of axonopathic polyneuropathy with severe sensitive affection.

CLINIC JUDGEMENT, DIFFERENTIAL DIAGNOSIS, PROBLEMS IDENTIFICATION

After several urgency visits for his symptomatology, with abnormal test results, and with the pathological background of the patient, it suggests the possibility of a vasculitis. The diagnose is confirmed for Churg-Strauss syndrome.

TREATMENT, ACTUATION PLANS

Follow-up and pharmacological treatment is carried out by autoimmune diseases service of internal medicine in the hospital.

EVOLUTION

Currently, the patient is stable, even though worsening of respiratory episodes and peripheral neuropathy.

CONCLUSIONS

The applicability for Family and Communitarian Medicine is based in the opportunity for a evaluation with a global vision of all the background, symptoms and different diseases of one patient, thus allowing the realization of a single diagnosis.

Keywords: S Vasculitis, Churg-Strauss syndrome, eosinophilia.

Diagnosis criteria

American college of rheumatology criteria*

Asthma (a history of wheezing or the finding of diffuse high-pitched wheezes on expiration)

Eosinophilia >10 percent on differential white blood cell count

Mononeuropathy (including multiplex) or polyneuropathy

Migratory or transient pulmonary opacities detected radiographically

Paranasal sinus abnormality

Biopsy containing a blood vessel showing the accumulation of eosinophils in extravascular areas

*Four of the six criteria needed and biopsy evidence of vasculitis

Acenocumarol management in primary care

Jose María Fernandez Gonzalez¹, Pedro Guijo Gonzalez², Inmaculada Saucó Colon³

¹HEALTH CENTER OF LA GRANJA-MANUEL BLANCO, HOSPITAL OF JEREZ DE LA FRONTERA.

²INTENSIVE CARE UNIT HOSPITAL OF JEREZ DE LA FRONTERA

³HEALTH CENTER OF SAN BENITO, HOSPITAL OF JEREZ DE LA FRONTERA.

OBJECTIVE:

To describe the INR values of patients of two health centers (HC) anticoagulated with Acenocumarol.

MATERIAL AND METHODS

Retrospective cross-sectional study.

Scope: Primary Care. N: 45000.

Inclusion: Patients on anticoagulant therapy during a year in monitoring in Primary Care

Main variables:

- INR values.
- Anticoagulant Treatment: acenocumarol.
- Secondary Variables: sex, age range
- INR in therapeutic range (TR): 2-3;
- Patients with appropriate control INR: INR values in TR above 60% in 6 months (depending on the Spanish Agency for medication).

Registration: Excel table. Analysis: statistical program IPSS.

Description variables: quantitative measures central tendency and dispersion.

Qualitative: proportions; comparison: quantitative: t-student; qualitative chi-square.

Registration-based study in medical history with limitations of possible miss registration.

Anonymous data and treaties jointly

RESULTS

Patients In treatment with acenocumarol =734, Women: 468 (55 %), mean age 78 years.

Number controls INR=2852. arithmetic mean INR Average: 2.6. Women 78 % (2225); Men 22 % (627)

Percentage of controls with INR in RT according to sex: Women 48 %, men 45% (p: 0.1751)

Percentage of controls with an INR in RT according to age range: less than 70 years=3.2 %, between 70-90 years=64.3 %; older than 90 years=32.5 % (p: 0.0001).

Number of patients with registration of INR= 172 (23.4 %)

Of 172 patients, 114 (66 %) have the average of INR on TR.

Number of patients with more than 6 records of INR= 125, represents the 17% (125/734) of the patients.

With adequate control of INR (of 125) = 30 (24 %)

CONCLUSION

We are more controls of INR in women, but there isn't difference in the percentage of INR in therapeutic range.

25% of our patients has a INR control appropriate according to the Spanish Agency for medication.

Implementing an ultrasound service in primary care

A Carolina Berengue González, Adriana Ramos Ordoñez, Esther Casanovas Cuquet, Raquel Masvidal Moreno

Institut Catalá de la Salut, ABS Pineda de Mar, Barcelona, Spain

In 2014, was carried out a project called "EcoAP Project" which was based on abdominal ultrasound implement a Primary Care Team (PCT).

OBJECTIVE: Implement the abdominal ultrasound service in PCT.

Inclusion criteria was performed answering the following questions in order to select the suitable patients for being include in the Project:

- Nephritic colic: Discards / confirms obstructions?
- Gallstones: Discards / confirms stones / biliary obstructions?
- Hematuria: Discards / confirmed bladder injuries?
- Liver -Study: Discards / confirmed hepatic steatosis?
- Benign Prostatic hyperplasia: volume and voiding residue. Help therapeutic and management?

The work plan of the Project was focused in two phases:

The first phase, was focused in training a medical team to performe an abdominal ultrasound in order to track the patients by a sonographer, and to valorate if they have to referral at the hospital, where they were consulted in case of any doubts.

The second phase consisted in to implement the first 50 cases that were monitored with final assessment.

RESULTS:

- EcoAP cited: 54
- EcoAP made: 52
- EcoAP reasons:
 - Nephritic colic: Discards / confirms obstructions? 14
 - Gallstones: Discards / confirms stones / biliary obstructions? 5
 - Hematuria: Discards / confirmed bladder injuries? 3
 - Liver -Study: Discards / confirmed hepatic steatosis? 21
 - Benign Prostatic hyperplasiatate volume and voiding residue. Help therapeutic and management? 9
- EcoAP normal: 20
- EcoAP pathological: 32
- EcoAP: technical difficulty 5

CONCLUSIONS:

Each EcoAP made was sent to their referring doctor for follow up.

The primary care team has aimed to continue growing, increasing EcoAP template and stimulate new tecnologies applicable to primary care.

Patient with hyperglycemia in a hospital emergency department

Jose María Fernandez Gonzalez¹, Cristina Bitaube Mata², Mauricio Ramirez Temblador³

¹HEALTH CENTER OF LA GRANJA-MANUEL BLANCO, HOSPITAL OF JEREZ DE LA FRONTERA.

²EMERGENCIAS HOSPITAL SERVICIO ANDALUZ DE SALUD DE JEREZ DE LA FRONTERA

³EMERGENCIAS HOSPITAL PUERTA DEL SUR JEREZ DE LA FRONTERA

OBJECTIVES

The hyperglycemia is an important health problem both because of its high prevalence and the associated complications.

OBJECTIVES: To describe the clinical profile of the sick consultation at a Hospital Emergency Department by hyperglycemia and analyze the actions on the treatment to the hypoglycaemic high.

MATERIAL AND METHOD

Retrospective study conducted at the Emergency Department. Consecutive patients were included served during a period of six months by hyperglycemia.

RESULTS

A total of 115 patients were analyzed, 70 women and 45 men. The mean age was 60.5±18.9 years. 16 Patients had a diagnosis of type 1 DM (13.9 %), 89 DM type 2 (77.4 %) and 10 diabetic presented debut (8.7 %). The average blood glucose level was 422.9 ± 132.8 mg/dL[196-963]. The 28.7 % were treated with oral antidiabetic agents. The 29.6 % with insulin, and 28.7 % in combined treatment. A 13% did not treatment. 29 (25.2 %) went to observation, 13 (11.3 %) presented ketoacidosis. The 10.4 % were previously treated with corticosteroids; 30.4 % had a concomitant disease; 23.5 % had poor control of your blood sugar and a 35.7 % did not know the cause of decompensation. 65 Patients (56.5 %) were referred to your primary care physician, 17.4 per cent to his home and a 19.1 % required hospitalization. The remaining 7% was allocated to external consultations or another hospital. Only 22,6 % introduced a modification of the antidiabetic treatment to the usual high.

CONCLUSIONS: patients with hyperglycemia seen in the Emergency Room are derived in its majority to your primary care physician for further control. The predominant clinical profile was women with type 2 diabetes mellitus and pre-treatment. Most of the treatments were not modified.

Three Cases of Allergic Contact Dermatitis Induced by Nitrofurazone

Gülben Sarıcı¹, Yasemin Korkut²

¹Department of Dermatology, Dumlupınar University, Kütahya, Turkey

²Department of Family Medicine, Dumlupınar University, Kütahya, Turkey

AIM:

Topical nitrofurazone frequently causes severe allergic contact dermatitis(ACD),necessitating hospitalization.ACD is a delayed–type hypersensitivity reaction that is elicited when the skin comes in contact with a chemical to which an individual has previously been sensitized.

Case 1: 40-year-old patient whose hands burned by hot water a month ago was admitted to our clinic due to the not healing of the burn area and severe pruritus.Hand was covered with erythematous vesicles except burned areas in the examination of the patient undergoing dressing with nitrofurazone ointment(Furacin®)since the first day. It was considered that ACD was depending on nitrofurazone.Nitrofurazone treatment was terminated.The patient was hospitalized and then systemic methylprednisolone 40 mg was started.Improvement in symptoms was observed after one week.Steroid therapy is gradually reduced and stopped.

Case 2: There were pruritic,erythematous,squamous plaques spreading to the whole body from the nail of the patient using nitrofurazone ointment due to ingrown nail.It was prominent on the face.Nitrofurazone treatment was terminated.The patient's symptoms were decreased with systemic methylprednisolone.

Case 3: The patient whose right toes amputated due to diabetic foot have begun to pruritus 3 days after starting dressing with nitrofurazone ointment for wound site and it was gradually spread.Nitrofurazone treatment was terminated.The patient was hospitalized and then systemic steroid therapy was started.The symptoms of patients were decreased after 1 week.

CONCLUSION: The use of nitrofurazone was abandoned in most countries due to high in the incidence of contact sensitivity. This topical antibiotics which has a high chance of developing ACD is still used in many countries because it is cheaper and easily accessible.It is necessary to pay attention to such side effects because the use of this agent which causes generalized lesions,usually requires hospitalization and systemic steroids for the treatment of patients is common among family physicians.

From hiccups to a hidden diagnosis

Melahat Argun¹, Pakize Sucu², Bircan Kanyilmaz¹, Emin Pala¹, Sema Basat³

¹Department of Family Medicine, Umraniye Training and Research Hospital, Istanbul, Turkey

²Department of Pulmonology, Sureyyapasa Center for Chest Diseases and Thoracic Surgery Training and Research Hospital, Istanbul, Turkey

³Department of Internal Medicine, Umraniye Training and Research Hospital, Istanbul, Turkey

A 36 year old man presented to the family medicine clinic with a seven day history of persistent hiccups. He had no history of chronic diseases. On auscultation of the lungs, decreased breath sounds in lower lobes of the right lung were noted. A chest x-ray suggested pleural effusion with a blunting of the costophrenic angle of the right lung. Also there were suspicious opacities in the apical segments of the right upper lobe. For further investigation a computerized tomography was ordered and the result also verified pleural effusion and small calcified opacities and nodular lesions. Having considered the patient's young age, apical calcified lesions and same sided pleural effusion, tuberculosis is suspected and the patient is directed to a thoracic diseases specialized hospital for a comprehensive investigation.

Hiccups are usually precipitated by irritation of the diaphragm and/or stimulation of the vagus nerve. In this patient, irritation of the diaphragm by pleural effusion is resulted in hiccups. Persistent hiccups should be taken serious and investigated carefully to diagnose any hidden pathological cause. Although persistent hiccup is a very rare presentation of tuberculosis, it should not be dismissed since tuberculosis is still a major health problem in developing countries including Turkey. Primary health care physicians should keep in mind that a common symptom such as hiccup could be the tip of the iceberg.

Keywords: hiccups, pleural effusion, pulmonary tuberculosis

Assessment of The Forensic Cases Consulting to a University Hospital

Gökhan Eminsoy, Sinem Aydemir, Fisun Sözen, Altuğ Kut

Department of Family Medicine, Baskent University, Ankara, Turkey

Background & AIM: Family medicine deals with cases involving both the legal and medical aspects of patient care. The aim of this study was to investigate the features related with the referral reasons, sociodemographic features, judicial profiles and occurring date and time of all the child and adolescent forensic cases who were referred to university hospital. In this study, we aimed to draw attention to the forensic issues by retrospective investigation of 726 forensic cases.

METHOD: This retrospective study was conducted in a university Family Medicine Department in Ankara, Turkey. The data were collected from official hospital forensic reports. Patients' forensic sheets who applied to Başkent University Ankara Hospital in October 2013 and January, April and July 2014 were investigated for referral reasons, sociodemographic features, judicial profiles and occurring date and time.

RESULTS: 726 forensic cases admitted to Baskent University Hospital were evaluated. 25,1% were burns, 17,9% were traffic accidents, 16,7% were industrial accidents, 9,2 were beaten, 9,1 were falling down and 22% were the others like finger cuts, poisonings, traumas, suicides, object aspirations and gunshot wounds. 31,3% of the burn

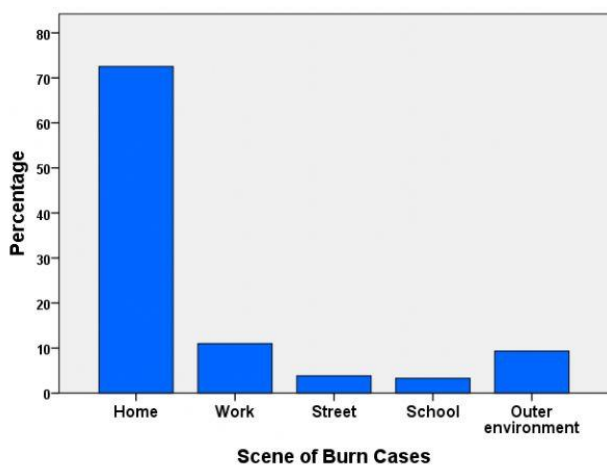

cases were tea scalds, median age was 15 (min:2;max:80) and 43,8% of them occurred between 18:01-24:00 pm.
CONCLUSIONS: The causes, referral reasons, sociodemographic features, judicial profiles and occurring date and time of forensic cases are very important when evaluating patient in Family Medicine practice. Primary care physicians have to handle both medical and forensic needs of their patients.
Keywords: Family medicine, forensic medicine, burns, accidents, violence, suicide, poisoning.

Background&AIM:

Workers are struggling to provide safe and healthy working environment for many years. Unions at the forefront in this regard, have been emerged to cover and protect economic, social and political rights of all employees. All employees are influenced by the situation in the working environment vice versa work environment, job satisfaction, work satisfaction levels also affects working environment.

For better working conditions and health workers' being healthy, it's necessary to define the perspectives of employees objectively.

Our aim is to determine health care workers' being a union member or not, their level of job satisfaction and anxiety.

Methods

Volunteered health workers working at a university hospital included this cross-sectional descriptive study to determine job satisfaction by "Minnesota Job Satisfaction Questionnaire(MSQ)", and anxiety by "State-Trait Anxiety Inventory(STAI)".

Descriptive statistical analysis of the data was performed using SPSS 15.0 software as well as the chi-square and t tests. $p < 0.05$ was considered significant.

Results

According to initial findings of the participants 53(55%) were female, 44(55%) were married and mean age was 35.71 ± 8.47 (min:24-max:60)($n=80$). Mean of years worked is found 11.25 ± 8.84 (min:1-max:32). Doctors' (53)66.3% were more than nurses (8)10%.

Majority of them (58)72.5% stated that they are member of a union. Causes of being a member were stated as "to be organized", "defend my rights and to be strong together" and "to be contributions to the professional development".

Being not a member of a union was stated as "undecided", "do not trust the community," "I find it unsatisfactory".

MSQ total score mean was 3.4(min:2.15-max:4.60). STAI mean scores were 40.98 ± 9.84 (min:22-max:68) and 42.26 ± 7.56 (min:27-max:60) respectively.

Conclusion

Health care workers' job satisfaction and status of anxiety were moderate according to initial results. There was no difference between being a union member, age, gender, education level and job satisfaction or status of anxiety ($p > 0.05$).

Data collection is ongoing.

Keywords: union membership, anxiety, job satisfaction, health workers

Common Mental Disorders amongst Migrant Factory Workers in Urban, Mainland, China

Kendall Anne Searle

Department of Primary Health Care, Monash University, Melbourne, Australia

Background

Over 173 million adults live with some type of mental disorder in China. Estimates suggest that 91% of these adults have never received professional care for their condition. Migrant are particularly unlikely to receive mental health care. This is despite the fact that the nature of their employment (physically demanding; repetitive; long hours; poor conditions; and low wage) and isolation from their usual support network puts them at high risk of developing these complaints.

Objectives: To conduct a systematic review according to the PRISMA 2009 guidelines

Methods: Medline/Ovid SP, EMBASE/Ovid SP, PsychINFO/EBSCO, CINAHL/EBSCO and reference lists were searched for English only articles to May 2014. Inclusions:- i) identified "Migrant Factory Workers" ii) investigated any "common mental disorder" as diagnosed by an internationally recognized standard or a "well-being" proxy marker for good mental health; c) primary research conducted in urban mainland China; d) participants of 16+ years. Exclusions:- Reviews; editorials; letters; commentaries; and PhD reports. All titles, abstracts, and full text articles were independently reviewed by two researchers with non-agreement resolved through discussion. A descriptive data analysis and assessment of bias was performed.

Results: The search yielded 542 articles of which 16 studies (24 articles) were included representing findings from 40,658 participants overall and 30,471 "migrant workers". Factory workers were recruited as part of a household, occupational, community-based or hospital sample or targeted at a factory (6 studies). Guangdong was a key provincial research site with all factory-specific research being conducted in Shenzhen. Research sought to identify risk/protective factors or obtain prevalence estimates. All studies were observational in nature. Prevalence values could not be pooled due to diversity of screening tools, participant profiles, sampling approaches and innate bias from cross-sectional study design. Collectively, these studies identified 29 different risk factors potentially associated with poor mental health outcomes in this population.

Keywords: Migrant Factory Workers; Common Mental Health Disorders, China

Fig 1 Systematic Review Selection Process

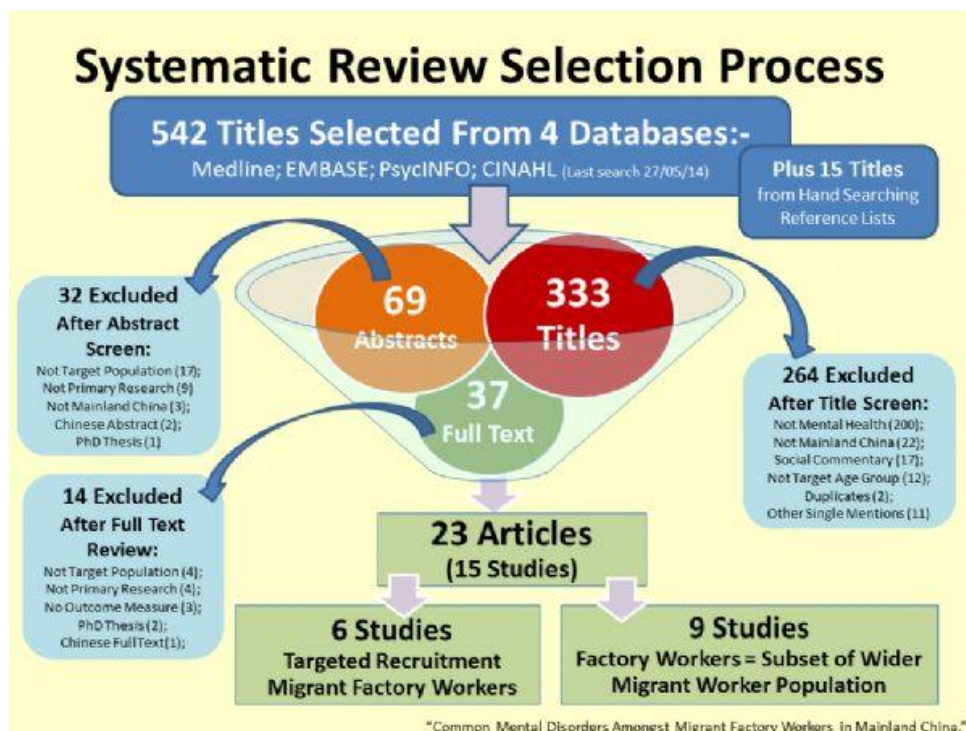

Fig 2 Research Coverage

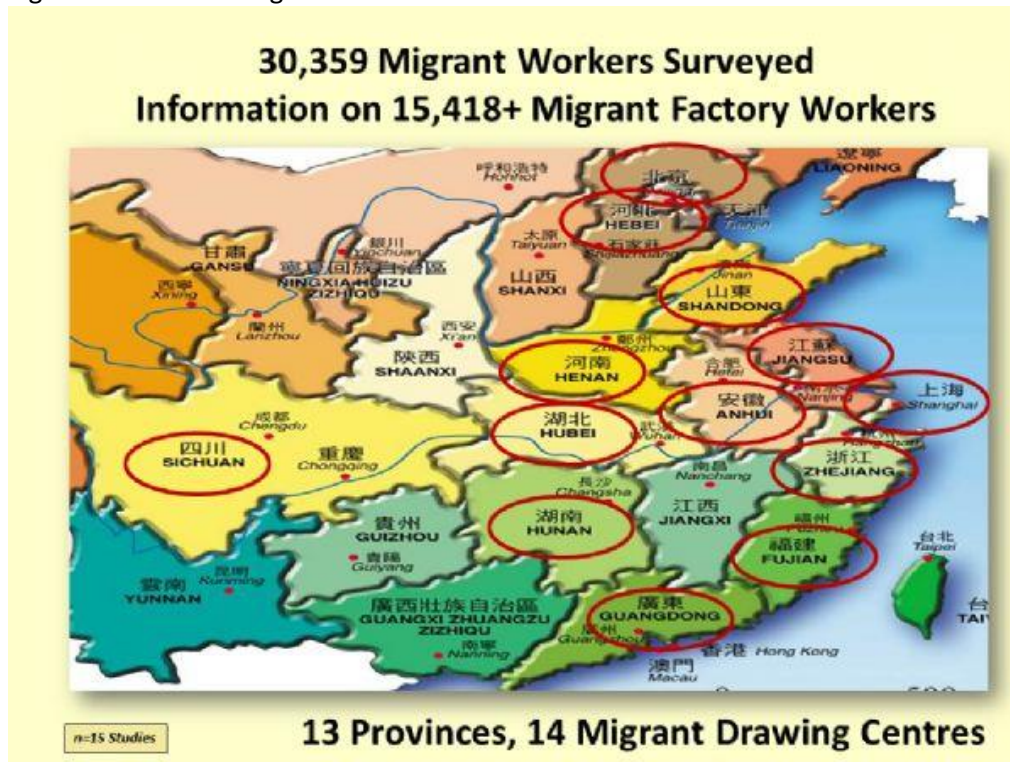

Fig 3 What do we know about the mental health of these migrants?

What do we know about the mental health of migrants working in electronics & textile factories in mainland China?

Prevalence of a Common Mental Disorder

- **Established migrants:**- 21.4% clinically relevant depression symptoms based on CES-D Score (Weissman cut-off of 16).
- **Female only, exclusively dorm-based:**- Lower SF-36 (70.5) than Chinese Female norms (75.5).
- **Female only, majority dorm-based:**- 35% Mentally unhealthy* based on BSI (Ritsner GSI thresholds).
- **Males & females, medium-sized factories:**- More symptoms on SCL-90 (7.71) than permanent residents (2.57).

Risk Factors With Positive Associations (s=15):

- **Demographics:**- young/old; single/married; low/high educational level
- **Migration:**- act of; number of; isolation; separation from partner; increased time in host city;
- **General Health:**- digestive/urinary/gynaecological disease; anaemia; low 2-week morbidity rate; muscular soreness
- **Work Related:**- manual work; long hours; low salary; stress; money difficulties; perception of other workers' salary
- **Interpersonal:**- tensions/conflicts; discrimination; stigma
- **Lifestyle:**- casual smoker; poor social life

Reviewing The Specific Problem Solving Core Competency of Family Medicine Discipline with a Case Example

Yelda Zeliha Özer, Hatice Kurdak

Department of Family Medicine, Cukurova University, Adana, Turkey

AIM: A case will be discussed in the context of specific problem solving core competency.

METHOD: A twenty-nine years old man applied to our clinic. His request: getting a medical certificate, his concern: getting it in a short time. He didn't have any active complaints or previously detected diseases. Upon further acquaintance, it was discovered that he was an international-postgraduate student hurrying to report his medical forms to extend his stay in the country (the context). There were no special circumstances regarding his medical history. His physical examination was normal except for a 0.5x0.5cm mobile non-rigid bilateral submandibular lymphadenopathy.

RESULTS: Blood tests were performed according to the medical certificate and mild neutropenia was detected. After this a peripheral blood smear was done where the results were normal and no atypical cells were observed (Crombie's eliminative diagnosis). When valid evidence that is relevant to this situation was searched, it was discovered that Benign Ethnic Neutropenia had high prevalence in Africans (patient-oriented evidence that matter-POEM). After a hematology consultation the tests were repeated one month later and the results were approximately the same (Table 1).

DISCUSSION: This case is a good example of "low prevalence medicine" and "quaternary protection". Neutropenia diagnosis includes an algorithm ranging from complete blood count to bone marrow aspiration biopsy. Understanding the applicants' contexts and using POEM may protect them from unnecessary examinations and being labeled as 'patients'. This core competency requires the ability of relating specific decision making processes to the prevalence/incidence of illness in the community; selectively gathering and interpreting information and applying it to an appropriate management plan in collaboration with the patient; adopting incremental investigation, using time as a tool and tolerating uncertainty; intervene urgently when necessary; making effective and efficient use of diagnostic and therapeutic interventions.

Keywords: Neutropenia, specific problem solving, low prevalence medicine, quaternary protection.

Table 1

	Initial	Control
White Blood Cell	3.3 μ /L	3.5 μ /L
Neutrophil	39.8%	41%

Awareness of Late Adolescents With a Diabetic Family Member of Their Health Risks

Zeliha Özbakır, Altuğ Kut, Yasemin Çetinel, Fisun Sözen, Sinem Aydınay

Department of Family Medicine, Başkent University, Ankara, Tukey

BACKGROUND: Late adolescence is thought to be a period an adolescent establish the way of thinking and attitude. A diabetic member in a family influences the others as well, mostly the children and adolescents. The aim of this study is to assess the awareness of late adolescents who has a diabetic relative of the health risk factors related to this.

METHODS: This is a sectional type epidemiological study. This study is conducted in Ankara Baskent University with randomly chosen voluntarily participated 385 late adolescent between January 2015 and March 2015. Participants were given a questionnaire of 33 questions which aimed to determine their demographical characteristics, their habits related to diet and exercise and their knowledge, attitude and behavior about diabetes mellitus together with short form of Health Anxiety Scale. The participants were grouped into two as the ones with a diabetic member in their family and ones without. Data analysed via SPSS (Statistical Package For Social Sciences for Windows v.22,0, SPSS Inc. Chicago, IL) In addition to descriptive analysis Chi-square test, Yates corrected chi-square test and Fischer’s exact test are used with a statistical significance level of $p < 0.05$.

RESULTS: The healthy snack food choices of the late adolescents with a diabetic member in their family were significantly different from the other group’s. ($p < 0.001$) Attitude of the late adolescents who have a diabetic member in their family towards “The things a person with a risk of diabetes mellitus should care about his diet to decrease the risk” was significantly more correct from the other group ($p = 0.004$).

CONCLUSION: Late adolescents with a diabetic family member are not sufficiently aware of the health risks they have due to this. Improvement of the awareness and behavior of the late adolescents with a diabetic family member will be a preventive action towards diabetes mellitus.

Vaccination After Chemotherapy

Burcu Başaran¹, Çiğdem Apaydın Kaya¹, Perran Boran²

¹Department of Family Medicine, Marmara University, Istanbul, Turkey

²Department of Pediatrics, Marmara University, Istanbul, Turkey

BACKGROUND: Cancer affects children of all ages who may be at any stage of the childhood immunization schedule. Children who have not completed primary immunizations due to cancer and chemotherapy are particularly susceptible to vaccine-preventable infections. Chemotherapy causes immune depression in children and the vaccine activity is reduced. We present a case whose vaccination schedule have not completed due to cancer and chemotherapy.

CASE: A child, 4 years 4 months old, diagnosed as neuroblastoma stage 3 while he was 18 months old, came to the healthy child department after finishing his chemotherapy and radiotherapy; to complete the missing vaccinations. He had his last chemotherapy while he was 3 years 3 months old. The last vaccination had done while he was 12 months. After hemogram control, as it was normal; we decided to go on by the rutin vaccination schedule, and we planned to do 18 months vaccines diphtheria-tetanus-pertussis, haemophilus influenza and inactive poliomyelitis (DaPT-Hib-IPV). After serology control as Anti-HBS was negative, Hepatitis B virus vaccine was done as 3 dose. Because of we had done inactive poliomyelitis vaccine (IPV) before we haven't done oral poliomyelitis vaccine (OPV). We repeated conjugated pneumococcus vaccine. We have done Influenza vaccine. As the result of serology was negative we have done varicella and measles-mumps-rubelle (MMR) vaccines. Then 2 doses of Hepatitis A virus vaccine was done 6 months apart.

DISCUSSION: Vaccination is a complicated problem for oncology patients. There are lots of different implementation on literatures. Family physicians should plan the revaccination program special for each patient. Additionally special precautions about doses and duration of vaccines after chemotherapy should be noted. Vaccination of the hosts and care givers also should be considered.

Keywords: vaccination, chemotherapy, cancer

Recommendations for paediatric patients during and after chemotherapy

Vaccine	During Chemotherapy Concise Recommendation	After Chemotherapy Concise Recommendation
Poliomyelitis	Benefit of herd immunity Postpone if lymphocyte count $<1.0 \times 10^9/L^{**}$	Booster or vaccination 6 months after stopping chemotherapy
Diphtheria	As above, passive immunoprophylaxis and antibiotic prophylaxis in case of epidemic	Booster or vaccination 6 months after stopping chemotherapy (adult type vaccine for age >6 years)
Tetanus	Postpone if lymphocyte count $<1.0 \times 10^9/L^{**}$ Passive immunoprophylaxis, thorough washing and disinfection of wound, and antibiotic therapy for wounds at risk	Booster or vaccination 6 months after stopping chemotherapy
Pertussis	Postpone if lymphocyte count $<1.0 \times 10^9/L^{**}$ Passive immunoprophylaxis and antibiotic prophylaxis in case of epidemic	Booster or vaccination 6 months after stopping chemotherapy
Hepatitis A virus	Vaccination of the seronegative patients before starting chemotherapy in highly endemic areas; alternatively, passive immunoprophylaxis	Booster or vaccination 6 months after stopping chemotherapy
Hepatitis B virus*	As above	Booster or vaccination 6 months after stopping chemotherapy
Influenza	Vaccination yearly during fall; postpone if lymphocyte count $<1.0 \times 10^9/L^{**}$ Vaccination of family members Not administered to infants <6 months of age	Fall Season vaccination after 3 months from stopping intensive chemotherapy Not administered to infants <6 months of age
Meningococcus	Recommended vaccination prior to splenectomy Postpone vaccination if lymphocyte count $<1.0 \times 10^9/L^{**}$ Not administered if age <2 years	Not administered if age <2 years Booster or vaccination 6 months after stopping chemotherapy Booster after 3 years if vaccinated at age of 2-6 years
Haemophilus influenzae	Not administered if age <2 months Recommended vaccination prior to splenectomy Postpone vaccination if lymphocyte count $<1.0 \times 10^9/L^{**}$	Not administered if age <2 months Booster or vaccination 6 months after stopping chemotherapy
Pneumococcus	Recommended vaccination prior to splenectomy Postpone vaccination if lymphocyte count $<1.0 \times 10^9/L^{**}$	Booster or vaccination 6 months after stopping chemotherapy
Measles, Mumps, Rubella	Not administered if age <12 months Passive immunoprophylaxis in case of contact Vaccination of seronegative family members	Not administered if age <12 months Booster or vaccination 6 months after stopping chemotherapy
Measles	In case of epidemic, patient vaccination if adequate CD4+ immune recovery [†]	
Varicella	Postpone if lymphocyte count $<0.7-1.2 \times 10^9/L^{**}$ or the patient is not in remission for 12 months or is doing radiotherapy Not administered if age <12 months Vaccination of family members at risk; Postexposure prophylaxis within 96 hours from contact: hyperimmune Ig (0.2 mL/kg, max 10 mL) 96 hours after contact Acyclovir 4×20 mg/kg/day from the 7th to 21st days ^{**}	Not administered if age <12 months Booster or vaccination 6 months after stopping chemotherapy
Human papilloma virus	No data	Not administered if age <9 years Booster or vaccination 6 months after stopping chemotherapy
Rotavirus	No data	No data

Legend: *Observe a 4-week interval between 1st and 2nd doses and 3-month interval between the 3rd and 4th doses of vaccine for hepatitis B virus. Meningococcal and pneumococcal polysaccharide vaccines are not effective in children <2 years. Minimum age for conjugated vaccine is 6 weeks of age. Use pneumococcal conjugate vaccine followed, after at least 2 months, by the 23 polysaccharide vaccine. In case of splenectomy, give a booster after surgery. †Threshold level of CD4+ recovery for MMR vaccination: CD4+ $> 0.75 \times 10^9/L$ for children <12 months; CD4+ $> 0.5 \times 10^9/L$ for children aged 1-5 years; $>0.2 \times 10^9/L$ for children >6 years old and adults. **As suggested. ††Expert panel opinion. The use of acyclovir as postexposure prophylaxis has been successfully reported in immunocompetent host contacts with VZV. Reference:

Aortic aneurysm in young adult, an entity underestimated

Roldan García Sandra¹, García Moreno Samuel¹, Jiménez Herrera Carmen María¹, Muñoz Maya Ruth²

¹Centro de Salud Nuestra Señora de La Oliva. Alcalá de Guadaira. Sevilla.

²Centro de Salud Don Paulino García Donas, Alcalá de Guadaira. Sevilla

REASON FOR CONSULTATION: 32 year old man who consults for pain center-chest.

PERSONAL HISTORY: No cardiovascular risk factors. No toxic habits (alcohol, tobacco)

Family history: father died at age 54 of myocardial infarction.

CURRENT DISEASE: Pain center-chest radiating to intermittent left arm unleashed with the physical effort, without vegetative symptoms or dyspnoea. As happens in many cases for years, but in the last few days has increased in intensity and frequency, appearing progressively lesser efforts.

ADDITIONAL EXPLORATION AND TESTING

Good general condition, eupneic. Mild Engorgement jugular. peripheral pulses symmetrical.

Cardiopulmonary auscultation systolic murmur III/VI and diastolic III/VI aortic in focus.

Abdomen anodyne. MMII without edema or signs of Deep Venous Thrombosis. Rest exploration without findings.

Analytical: including D-dimers and cardiac markers

Chest radiography: normal.

Electrocardiogram: sinus rhythm to 70bpm, signs of growth in left ventricle with peaked T waves in chest.

Echocardiogram aortic aneurysm of 10cm to stretch upward. Aortic Valve trivalva with severe functional aortic insufficiency.

Angio-CT thoracic aortic dissection: type A Stanford with aneurismal dilatation of ascending aorta,

CLINICAL TRIAL

Type A Aortic Dissection of Stanford with ascending aorta aneurysm

DIFFERENTIAL DIAGNOSIS

- Musculoskeletal problems
- Pericarditis
- Ischemic Heart
- Pulmonary thromboembolism.

TREATMENT: Surgery, stents of ascending aorta.

FINAL COMMENT

- Abdominal Aortic Aneurysms are more frequently than the thoracic. Most are asymptomatic, you need a high index of suspicion, thorough medical history, risk factors, appropriate physical examination and imaging techniques. Chest pain is the main symptom of symptomatic aneurysms which tend to be very large and have a higher risk of rupture, by partnering with high mortality rates. May be suspected with chest x-ray, transesophageal ultrasound, Axial Computerized Tomography and Nuclear Magnetic Resonance of choice.

Keywords: Aortic Aneurysm, Chest pain, Aortic dissection

Angio-CT thoracic

Angio-CT thoracic aortic dissection: type A Stanford with aneurismal dilatation of ascending aorta

Chest radiography

Chest radiography: no pathologic signs

Quality And Popularity Of Turkish Health Web Sites

Selçuk Yıldız¹, Yusuf Üstü², Ebru Yılmaz¹, Sevim Öğülmüş¹, Ahmet Keskin², Mehmet Uğurlu²

¹Family Medicine, Ankara Atatürk Training and Research Hospital, Ankara, Turkey

²Family Medicine, Yıldırım Beyazıt University, Ankara, Turkey

Background and AIM:

Internet has been the way which is most commonly used to access information. Patients and their families search information about diseases and treatment methods on web. According to the data gathered in 2014 by the Turkish Institute of Statistics, Internet access in our country is about 60,2%.

METHOD:

Websites were identified by entering health-related key-words selected from the diseases that is common in the public. Diabetes, cervical cancer, asthma, hypertension, dementia, anemia, congenital hypothyroidism, hemorrhoids were entered as a keyword into two most popular search engines of Turkey based on the time of study: Google and Yandex. Analyzed websites were limited to the sites listed in the first three pages (30 sites) per search engine. At first, a list of 480 websites was generated. In the next step, by refining our search results 125 websites were duplicated, 30 weblogs, 77 websites in non-health related sites, 4 websites with presented technical problems were excluded. Then, 168 websites were included by tracking relevant link sites on the selected websites. Website assessment was performed by The Bomba and Land Index (version 2). Also we use Google PageRank to evaluate websites for popularity.

RESULTS:

The total Bomba score was $11,9 \pm 2,5$ (min.:5,2, max.:17,3). Most websites were in the moderate category ($8 \leq x \leq 11,99$). And Google PageRank mean score was 2,48 (min.:0, max.:8). There was no statistically significant association between Google PageRank with Bomba index variables.

CONCLUSIONS:

We think that our study will be followed by similar studies and thus we will have more data about the reliability of the information on Turkish-language websites which is about health.

Cutaneous complications due to hirudotherapy: a case report

Sevim Ogulmus¹, Ebru Yilmaz¹, Irep Karatas Eray¹, Selcuk Yildiz¹, Aylin Baydar Artantas¹, Havva Sahin Kavakli²

¹Department of Family Medicine, Atatürk Training and Research Hospital, Ankara, Turkey

²Department of Emergency, Yenimahalle State Hospital, Ankara, Turkey

INTRODUCTION: *Hirudo medicinalis* (leech) is an example of alternative therapeutics and have been used in the treatment of certain diseases since ancient times. The primary care physician should be aware of the cultural differences including religion and politics of her referred population so that she can be the mediator between medicine and the society. This study reports the case of a patient who showed cutaneous problems after leech therapy.

CASE: A 47-year-old woman contacted emergency services complaining about fever, nausea, anorexia, fatigue, cutaneous lesions which appeared two days prior. Six days before her current visit, she went to a different medical center complaining of varicose veins. The leech therapy was applied two days ago. Blood pressure:110/60mmHg, heart rate:85 beats per minute, respiration rate:18 per minute, temperature:38.6°C. At both sides of her legs, multiple erythematous and oedematous skin lesions were present. The largest one was 5cm in diameter. The center of the erythematous lesion was indurated which coincided with the site of the leech bite. WBC:10770/mm³, PLT:211000/mm³, PT:13.48 seconds, aPTT:30.9 seconds, INR:0.9. We consulted with The Clinic of Infectious Disease and they suggested starting an oral antibiotic treatment, wound dressing with antiseptic solution and elevation.

DISCUSSION: Today medicinal leeches are used in the treatment of various diseases such as thrombophlebitis, hypertension, varicose ulcer, skin and musculoskeletal diseases, in various surgical and traumatic conditions such as re-attachment of severed extremities, fingers, toes and ears. Infection is the most common complication of leeching(2-36%). Local hypersensitivity conditions including itching, blister formation, ulcerative necrosis, local tissue damage blood loss due to prolonged hemorrhage and skin marks left behind by impaired healing of leech bites are reported as postleeching complications. Further investigations are required to assess leech efficacy and safety in the treatment of disease. It is necessary to develop standart procedures for decreasing the complication rates.

A case diagnosed with neurofibromatosis type 2 after three decades

Fikret Merter Alanyalı¹, Suphi Bulğurcu², Berk Geroğlu¹, Ibrahim Çukurova²

¹Family Medicine Clinic, Tepecik Training and Research Hospital, Izmir, Turkey

²Ear, Nose and Throat Clinic, Tepecik Training and Research Hospital, Izmir, Turkey

INTRODUCTION: Neurofibromatosis type 2 (NF2) is a hereditary condition most commonly associated with bilateral vestibular schwannomas, also known as acoustic neuromas. These are benign (noncancerous) tumors that occur on the nerves for balance leading to the inner ear. Although these tumors are benign, they can cause hearing and balance problems.

CASE: A woman aged forty-four years presented into our clinic with a mass of 10x10 centimetres on her left side of throat's fifth division, toughness on left cheek and abducens nerve paralysis on her right eye. At presentation; her complaints were vertigo and mass on her throat. When we checked her history, we have found that she had been operated several times; from her right eye due to strabismus at age 12, from her both feet due to numbness and operated with total laminectomy and found neurofibroma and intramedullary tumor at age 23 and also a mass on her abdomen at age 23 but there was no diagnose. At age 32 a mass began to appear at her throat's left side but even the doctor's offerings our patient didn't want to have the surgery from her throat. After years passed, for the last two months there was a mass on her left cheek and the patient presented into our clinic. We have done fine needle aspiration from the mass but it was unidentified cytology. When we checked on radiologic imaging there were bilateral acoustic neuroma besides masses on her head. And finally we diagnosed the patient Neurofibromatosis type 2.

CONCLUSION: Even though the tumors are benign seen with Neurofibromatosis type 2, there could be severe damages and could effect life quality after years. If we check all systems on body, we could diagnose much early, prevent these conditions and treat them with drugs and radiotherapies.

Keywords: Neurofibromatosis type 2, bilateral acoustic neuroma, throat mass.

Brucellosis Like's Joints: A Case Report

Fatih Bağcier, Ayhan Kul, Meltem Alkan Melikoğlu

Atatürk University Faculty of Medicine, Department of Physical Medicine and Rehabilitation, Erzurum

INTRODUCTION: Brucellosis which is a endemic in Turkey, is a systemic infection which can affect any organ or system in the body. Since signs and symptoms of brucellosis resemble many other diseases, misdiagnosis and related increase in morbidity rate, are common. It most commonly involves the musculoskeletal system. We aimed to present a case who admitted with acute pain in the left hip area and was diagnosed of brucellosis sacroiliitis.

CASE: 27 year-old male patient was admitted to our clinic pain in the left hip area for a week. The pain did not decrease with rest and was intensifying at night. Fever was intermittent character rise up to 38,5. On physical examination left side FABER +, FADIR+. There was no history of trauma and comorbid disease. Joint movement was limited and tenderness. Other system examination findings were normal. **Laboratory FINDINGS:** hb:13,6mg/dl, sedim:20mm/saat, CRP:12 ALT:10iu/ml, creatinine:0,7mg/dl. Rose bengal:positive Wright: positive. Sacroiliac joint pathology was seen in pelvic radiographs. MRG: sacroiliitis was observed in the left joint. As a result brucella were detected in patients with sacroiliitis. Antibiotic therapy was given. The patient's pain reduced significantly. Physical examination was normalized.

CONCLUSION: Brucellosis often affects the musculoskeletal system. Osteoarticular complications of brucellosis occur in 10%-85% patients. Brucella infection may sacroiliitis, spondylitis, spondylodiscitis, arthritis, osteomyelitis, tenosynovitis or bursitis. The spine is the most common affected site and back pain is the most common clinical manifestation of brucellosis. Sacroiliitis of brucellosis usually occurs unilaterally in young patients. With appropriate treatment, recovery is observed in 60-90% of patients. Our case had been presented with unilateral sacroiliitis in accordance with literature. Extraarticular involvement was not seen. Brucellosis should be considered in the differential diagnosis of patients who present with musculoskeletal complaints in regions where brucellosis is endemic.

A 81 year-old female patient with left ptosis and drowsiness

Garrido Laguna Maria Cristina, Arrillaga Ocampo Idoia, Padial Reyes Irene, Navarro Robles Cristina, Fernandez Zambrano Maria

Las Lagunas Health Center, Mijas Costa, Malaga, Spain

CASE: Female patient, 81 years old, consults the primary care doctor, for mild left ptosis and drowsiness.

Personal medical history: hypertension, dyslipidemia, type 2 diabetes mellitus, chronic kidney disease stage 3B-A3, primary hypothyroidism, morbid obesity.

Previous surgery: cholecystectomy, hernia repair, bilateral faugetomia. No toxic habits.

During the first examination a left eyelid ptosis and a tendency to sleep is observed.

EXPLORATION AND INVESTIGATIONS:

Physical examination: normotensive, afebrile, drowsiness. Head and neck, cardiopulmonary auscultation and abdomen without abnormalities. Isochoric and normoreactive pupils, with left eyelid ptosis and limitation to move the eyeball vertically. Rest of cranial nerves without abnormalities. Symmetrical tendon reflexes present. Negative Babinsky.

Additional tests: general analysis results, including blood count, biochemistry, coagulation, TSH, vitamin B12, folic acid, autoimmunity, syphilis serology, Rickettsia, Borrelia, Brucella, Epstein-Barr virus, cytomegalovirus and human immunodeficiency virus are negative. Cranial CT (summary): cortico-subcortical lacunar infarcts and chronic atrophy. Cranial Magnetic Resonance (summary): moderate cortico-subcortical atrophy. Presence of acute stroke that affects the anterior portion of the midbrain and anterior nuclei of thalamus, of the artery of Percheron territory (midbrain and bithalamic)

DIAGNOSIS: acute / subacute infarction in the territory of artery of Percheron.

DIFFERENTIAL DIAGNOSIS: First is essential to consider a neurological process within the neurological processes that we study in this case are:

1. Massive subarachnoid hemorrhage: explosive characterized by headache, cerebrospinal fluid xanthochromia.
2. Myocardial blood bithalamic: Establishment of no subacute arterial territory.
3. Botulism: Vegetative signs, progressive downward paresis.

CONCLUSIONS: Given the neurological symptoms that the patient presents with involvement of the third cranial pair, in the differential diagnosis we need to consider the possibility of a stroke in the artery of Percheron. The diagnosis of this kind of stroke is based on clinical research and the scans results. The Nuclear magnetic resonance image shows in sequence T2 hyperintensity thalamus.

Keywords: Infarction, Percheron, thalamus

P-1381

Antibiotic resistance of Neisseria Gonorrhoea

Gülşah Yiğit

Department of Family Medicine, Marmara University Medical School, İstanbul, Turkey

INTRODUCTION: Neisseria gonorrhoeae is the etiologic agent of “gonorrhoea” which causes pelvic inflammatory disease, female infertility, neonatal ophtalmitis, transferred by sexual or perinatal way, effecting mostly mucous membranes of urethra, endocervix, less commonly rectum, scenes, vulva, oropharynx and conjunctiva.

Uncomplicated gonococcal infections are treated with 3rd generation cephalosporins; macrolide or tetracycline are added if non gonococcal urethritis co-exists.

Studies demonstrate that cephalosporins are the most effective antibiotics for N.gonorrhoeae and 250 mg single dose cephtriaxone is sufficient and no additional evidence exists for the use of higher doses. For combined therapy azitromycine is preferred to doxycycline due to anti-microbial resistance to tetracyclines. As floroquinolone resistance is low in Turkey single dose oral 500 mg ciprofloxacin or 400 mg ofloxacin or 500 mg levofloxacin is preferred. Unnecessary and inappropriate antibiotic use, risky sexual behaviors, iv drug use, homosexuality, genetic material exchange of the microorganisms at mucosal surfaces like pharynx, rectum are the factors well known to cause antimicrobial resistance.

AIM: In Turkey, gonorrheal infections are treated based on symptoms. This review is performed to investigate the studies related to antibiotic resistance of N.gonorrhoea in Turkey

METHOD: Turkish data base and pub med were searched by using the key words: “N.gonorrhoea, antibiotic resistance”. As the number was limited all the studies found were reviewed and analyzed.

RESULTS: The studies demonstrated 22-71% resistance for penicillin, 4,8-22% for tetracyclin, %5 for ciprofloxacin and ofloxacin and almost none for cephtriaxone, cephixime and cefuroxime.

CONCLUSION: To raise the success of ampic treatment, to follow antimicrobial resistance development and to develop up-to-date guidelines in Turkey, national surveillance programme and screening and antimicrobial sensitivity researches for gonococcus is necessary.

Disabled children and their impact for the parents

Millena Gomes Pinheiro Costa, Camilo Franco Ribeiro Koleilat, [Lara Louise Guimarães](#)
University Federal of Goiás, Goiânia, Brazil

BACKGROUND: The birth of a child brings a lot of changes on the family structure, in which the parents feel all of them on so many different everyday moments. They create expectations around the baby: witch sex it will be? What career it will follow? And according to what they want they project their “perfect” baby in their minds. The birth of a disabled child is an expect situation and confronts all that hope in a bigger way. **METHOD:** The paper is a literature review based on full texts published in Portuguese and English in the last years. The search was performed in Pubmed and Scielo using “disable children” and “parents”. **RESULTS:** One of the first worries with a disable child is to know and understand what that deficient is and what it’s prognostic. But independent of this disable, the child will need atention and careful beyond than expect. And brigis a lot of preoccupation with the future of the kid, if he or she will be able to support it self. The denial of the parents can also be a big problem, because makes they look for help and treatment, if it’s necessary, late. All of this factors cause psychologically difficult to the parents, like afraid to fail with the education, angry because it’s happening to them, confuse with the unknown. **CONCLUSION:** Having a disable baby can bring a lot of changes in the family, and both parents and siblings go to challenges. So that they succeed they need the most help as possible, like health professionals that can guide the family how is the best way to lead with the situation, and that a disable child, even with all it’s limitations can return love and becomes part of the family.

A Giant Fetal Cystic Hygroma: A Case report

[Vasfiye Demir](#)¹, Mehmet Siddik Evsen², Senem Tunç², Pakize Gamze Bucaktepe¹, Kübra Dursun²

¹Department of Family Medicine, Dicle University School of Medicine, Diyarbakır, Turkey

²Department of Obstetrics and Gynecology, Dicle University School of Medicine, Diyarbakır, Turkey

Cystic hygromas(CH) are congenital malformations of the lymphatic system appearing as single or multiloculated, fluid-filled cavities found mainly in the neck and axilla region. % 80 percentages of CH are located at the posteriolateral part of fetal neck. We presented a case which has giant cyctic masses both on the neck, arm,shoulders and thorax.

A 33 year old woman, gravida 7 parity 5 abortus 1 presented to obstetrics policlinic with labor pain. Patient went under ultrasonography(USG) and a single female fetus with anhydramnios detected at the examination. Biparietal diameter and head circumferences were compatible with 32 gestation week while abdominal circumferences was 36 week. USG detected multiseptated giant masses located both at the neck, shoulders, arms, back and surrounding chest wall. The diameter for cystics were fluctuating between 5cm to 20 cm. Woman had no family history of congenital abnormalities.

Cesarean section had recommended to woman. Due to woman’s request a vaginal birth take place and a female infant was delivered with a Apgar index of 0 at 1 min and 4 at 5 min. Infant was resusiated for two minutes and then transfered to new born intensive health care unit but died in two days Infant’s weight was 5000 gr and height was 55 cm. Physical examination revealed huge cystic masses at the neck, upper trunk and upper the limbs and also polidaktili at the left hand. At the postnatal USG examination findings were compatible with CH and no other abnormalities except polidactili was detected at the examinations.

% 50-80 of CH cases are presented together with chromosomal abnormalities. A fetus with CH need to be screened for other anomalies. Antenatal screening is crucially important to detect this abnormalities and also making a decision about the way of deliver and give the decision of terminating the pregnancy.

The Evaluation of The Residents' and The Final-Grade Medical Students' Knowledges, Attitudes and Views Regarding Forensic Report Writing

Vasfiye Demir¹, Tahsin Çelepkolu¹, Cem Uysal², Mustafa Korkmaz², Pakize Gamze Bucaktepe¹, Yılmaz Palancı³, Adil Bucaktepe⁴

¹Department of Family Medicine, Dicle University Faculty of Medicine, Diyarbakır, Turkey

²Department of Forensic Medicine, Dicle University Faculty of Medicine, Diyarbakır, Turkey

³Department of Public Health, Dicle University Faculty of Medicine, Diyarbakır, Turkey

⁴Department of Administrative Law, Dicle University Faculty of Law, Diyarbakır, Turkey

Forensic report is an official paper submitted to state offices documenting the questions answered by a physician as well as the opinion of the physician regarding the medical state of the person. Errors in forensic report writing may lead to irreversible results and delays in forensic practices and also may result in legal liability for the physician.

The aim of this study was to evaluate and compare the knowledge, attitudes, and views of the residents specializing at medical sciences and the final-grade medical students (FGMS) regarding forensic report writing. The study had a cross sectional descriptive research design and was approved by the local ethics committee. The study included 175 residents and 94 FGMS who are studying in Dicle University School of Medicine. The participants were administered a 28-item questionnaire between December 1, 2014 and June 1, 2015. Data were analyzed using SPSS 22.0.

The results revealed that 94% of residents and 100% of FGMS regarded themselves as incompetent in forensic medicine ($p < 0.000$), and only 30% of residents and 5% of FGMS indicated that their forensic medicine education was sufficient ($p < 0.000$).

It was also revealed that 89% of residents received no forensic medicine education after graduation, whereas 65% of residents and 73% of FGMS declared that they were willing to receive further forensic medicine education ($p = 0.357$).

Moreover, 30% of residents and 77% of FGMS indicated that they had no information regarding the legal liability of forensic reports and 34% of residents ($p < 0.000$) and 73% of stated that they had no information regarding the effectivity of forensic reports on legal proceedings ($p < 0.000$).

The study revealed that most of the physicians consider themselves as incompetent in forensic medicine. The study also demonstrated that pre-graduation forensic medicine education should be intensified and also post-graduation education programs should be designed.

Investigation of Factors That Effect The Relationship Between Body Mass Index and Self Esteem In University Students

Nida Şebnem Altun¹, Berrin Telatar², Can Öner², Funda Elmacioğlu¹, Adnan Aydın¹

¹Istanbul Bilim University, School of Health, Nutrition and Dietetics Department, İstanbul, Turkey

²Istanbul Bilim University, School of Medicine, Family Medicine Department, İstanbul, Turkey

Introduction and AIM:

Self-esteem is a person's self awareness, his love against himself, respect and trust feelings. There are studies indicating that in obesity self-esteem is decreased. Our study is designed to investigate the factors that influence the relationship between body mass index (BMI) and self esteem.

MATERIAL-METHOD:

This descriptive study is conducted with students who attend Vocational School for Health Services in a private university in Istanbul between March - May 2015. There were totally 1388 students but 458 students accepted to participate in this study. A demographic questionnaire and Rosenberg self-esteem measuring scale of ten questions was applied.

In the calculation of the Rosenberg self esteem scale, it was defined as high (0-1 scores), mid (2-4 score scores) and low (5-6 scores). Data was analyzed with SPSS 15.0 software package.

RESULTS:

253 (55.2%) person was female and 200 (43.7%) were male. 58 (12.6%) was weak, 324 (70.7%) was normal, 59 (12.8%) was slightly overweight and 17 (0.3%) was obese. The average self-esteem score was 1.35 ± 0.53 . 308 (67.2%) individuals had high self-esteem, 138 people (30.1%) had medium self-esteem only 12 people (2.6%) had low self-esteem. There was no significant association between self-esteem and BMI; self-esteem and gender. There was no significant relationship between self-esteem and individually described weight, the number of people living together, income statement, cigarette use ($p > 0.05$).

In our study, none of people with the low self-esteem were detected obesity and was not detected decrease in self-esteem scores in any of the obese persons.

CONCLUSIONS:

A significant association between BMI and self-esteem could not be determined. It will be appropriate to conduct this study in crowded obese and in older groups and investigate not only obesity but also psychosocial factors in those with low self-esteem.

Does smoking status change the mean platelet volume levels?: A retrospective case-controlled study

Oğuzhan Tezcan, Hülya Yıkılkan, Cenk Aypak, Derya İren Akbıyık, Süleyman Görpelioğlu
Department Of Family Medicine, Dışkapı Yıldırım Beyazıt Training and Research Hospital, Ankara, Turkey

BACKGROUND & AIM:

Platelets play a crucial role in the inflammatory processes via secreting proinflammatory factors, growth factors and chemokines. Mean platelet volume (MPV) have been reported as a platelet activation marker. MPV can be easily measured by routinely used automated hemocytometers and is included as a parameter in complete blood cell (CBC) analysis. The correlation between MPV and various diseases such as acute coronary syndrome, peripheral artery disease, Alzheimer's disease, psoriasis vulgaris etc. have been reported. The aim of our study was to investigate MPV levels in non-smokers, passive smokers and smokers and to evaluate association between MPV and the smoking status.

METHODS:

This was a retrospective case-controlled study. Total of 118 patients who visited Dışkapı Yıldırım Beyazıt Training and Research Hospital Family Medicine Department Outpatient Clinics in 2015 were enrolled in our study. The study was designed in three groups, non-smokers (n:37), passive smokers (n:40) and smokers (n:41). MPV values were gathered from patients previous CBC results and were compared between these groups.

RESULTS:

The mean age was 47.9±18.1 (min:18,max:79) years. Of all patients, 48.3% (57) were females, 51.7% (61) were males. MPV mean values for non-smokers, passive smokers and smokers were 8.73±1.0 fL (6.7-10.9); 8.8±1.4 fL (6.6-11.6), 9.1±1.5 fL (6.3-12.0) respectively. There was not a statistically significant difference in terms of mean MPV levels between these three groups (p>0.05).

CONCLUSIONS:

The MPV did not differ with smoking status in our study. Further studies with higher sample sizes are needed in order to confirm our study results.

Keywords: Mean platelet volume, smoking, passive smoking

P-1387**Rapidly Progressive Glomerulonephritis (RPGN): a case-report**

Muhammed Atmaca¹, Sevim Ogulmus¹, Irep Karatas Eray¹, Yusuf Ustu², Mehmet Ugurlu²

¹Department of Family Medicine, Atatürk Training and Research Hospital, Ankara, Turkey

²Department of Family Medicine, Yıldırım Beyazıt University Faculty of Medicine, Ankara, Turkey

INTRODUCTION: Together with the technological development, test results could easily take the place of medical history and clinical examination during patient administration. Sometimes, minimal changes in lab findings could be normalised as "limit value", or many diagnosis could be bypassed due to alack of correlation between clinical and test results. Here, a case of RPGN diagnosed lately due to the ignored clinical findings is presented.

CASE: 50 years old lady was applied to the gastroenterology clinic with nausea, swelling in face and legs ongoing for one month. The general condition was good and the vitals were stable. There was a tenderness in the lower right quadrant and bilateral pretibial edema (+/+).

Creatinine was 1,8 mg/dl and urea level was 60 mg/dl in lab examination. No pathology was evident in upper abdominal USG. Peptic ulser therapy was started. The patient was back with ongoing complaints with the addition of fatigue, vomiting and hematuria. The blood pressure was 140/80 mm Hg. The pretibial edema was then ++/++ and creatinin was 9,2 mg/dl. The patient was consulted to the nephrology clinic and hospitalized and dialyzed. ANA and PANCA was positive with advanced diagnostic procedure. The biopsy result was glomerulosclerosis compatible with RPGN and steroid therapy was started.

DISCUSSION: RPGN is characterised with rapid and progressive loss in kidney functions and progresses to terminal kidney failure in weeks or months. The prevalence is 0,2-7 in a million. Though it is rare for family physicians, it is a disease of probable viral aetiology and high-mortality. Early the high level of creatinine is diagnosed, better the prognosis and survival are.

CONCLUSION: Family physicians meet dissociated disorders frequently, so they should use not only the test results, but the clinical findings as well, together with better evaluation of medical history and physical inspection findings.

Keywords: RPGN, Family physicians, early diagnosis

P-1388**Family medicine core competencies: What is the meaning of "Community Orientation"?**

Elif Altunbaş Ateş, Turan Set

Karadeniz Technical University Medical Faculty, Department of Family Medicine, Trabzon, Turkey

BACKGROUND&AIM: To understand the basic features of the discipline of family medicine is important for practices. In this study, it is intended to explain core competency of family medicine "Community Orientation".

METHODS: Textbooks, Articles in the PubMed&Google search, The European Definition of General Practice/Family Medicine-2011 sources have been read and commented.

RESULTS: There are 12 main features of the discipline of family medicine defined (Figure 1). They can be clustered into six core competencies. According to community-oriented model, family doctors should consider individual problems in the context of the health needs of the community and other professionals and agencies. The discipline recognizes that it has a responsibility both to the individual patient and to the wider community in dealing with health care issues.

DISCUSSION: Patients who didn't apply to office (eg. unvaccinated, blood pressure was not measured at all) should be addressed for care as the applied ones for well-child examinations, immunizations, acute and chronic diseases of all kinds.

Community-oriented Primary Care process occurs by accomplishing the following steps:

- Defining and characterizing the community
- Identifying community health problems
- Developing emphasis programs to focus the resources of the practice on the most common community health problems
- Monitoring the impact of each program and making modifications to better address the need.

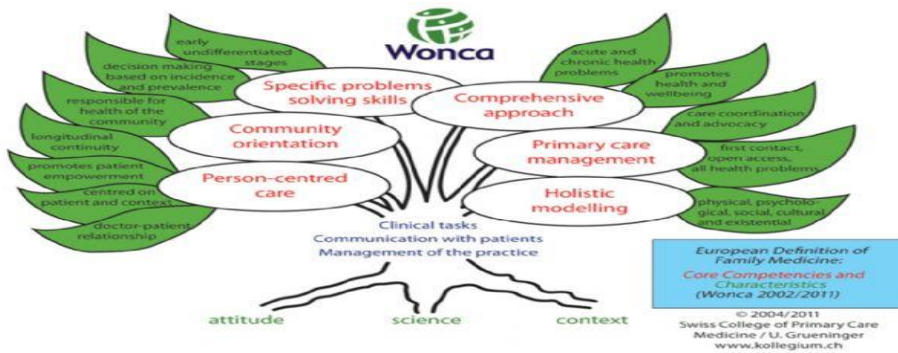

Family doctors should manage diseases most commonly seen at their population. Family doctors working in Turkey should not know 'Rocky Mountain Spotted Fever'. But they have to define 'Behçet's Diseases' because of the prevalence.

CONCLUSION: Community oriented care by a family doctor work must first begin by defining its population. They should be aware of being a part of the health care providers network. They should know the community health resources and these resources should be used for the benefit of both the patient and the community.

Keywords: Family doctors, core competencies, community-oriented

Tinea incognita a case report

Nazlı Dizen Namdar¹, Yasemin Korkut²

¹Department of Dermatology, Dumlupınar University, Kütahya, Turkey

²Department of Family Medicine, Dumlupınar University, Kütahya, Turkey

Introduction

Tinea incognita arises due to wrong diagnosis by the application of topical or systematic corticosteroid to the dermatofit infected zone. Lesion, as generally asemptomatic, may be accompanied by itching and pain. On the dark red or violet colored lesion, papules and pustules can be observed. Systemic antifungal is required for the treatment. The case in here presented is a tinea incognito diagnosis.

Case

40 years old man presented with pruritic, erythematous patch located on the inguinal area. The patient had a history of intermittent topical corticosteroid (clobetasol propionat) use for 2-3 years. The dermatologic examination revealed bilateral, sporadically and slightly squamous, erythematous, sharp edged and edge activated plaque form lesion. No pathology was detected in other systemic examinations and routine laboratory tests proved normal. The requested dermatology consultation with the microscopic examination of lesion showed fungal hyphae and spores. The patient was treated with 250mg/day oral terbinafine and topical antifungal for a month. The examination after two weeks presented nearly total recovery in the lesion.

Discussion

Superficial fungal infection often encountered by doctors causes serious trouble in diagnosis and treatment for same cases. Incorrect diagnosis and treatment suspends recovery process. The delay due to incorrect diagnosis

raises treatment costs and results with difficulties. Besides, wrong medication generates sides effects on the patients, prolonged disease and treatment process decrease the life quality of patients. So many people consult to Family Medicine departments with dermatological lesions and to prevent incorrect diagnosis and treatment these lesions should be examined seriously.

Nickel Contact Dermatitis On The Earlobe And Secondary Bacterial Infection: A Case Report

Oğuzhan Tezcan, Hülya Yıkılkan, Cenk Aypak, Derya İren Akbıyık, Süleyman Görpelioğlu
Department Of Family Medicine, Dışkapı Yıldırım Beyazıt Training and Research Hospital, Ankara, Turkey

INTRODUCTION: Allergic contact dermatitis is characterized by the delayed hypersensitivity reaction that occurs when an allergen comes into contact with previously sensitized skin. Signs and symptoms of the disease include rash, itching, dry, cracked, scaly skin, blisters, swelling, burning, tenderness. Skin dryness and damage of outer layer of skin by itching increases the secondary bacterial infection risk. The patch test is used to identify the causative allergen and can also detect metal hypersensitivity for nickel, gold, chrome and cobalt.

CASE: A 21-year-old man presented with painful swelling on his right earlobe after starting to wear nickel earring. He reported that it started as a pruritic rash and after 5 days it swelled and became very tender. Purulent fluid was coming from the spontan laceration occurred on the posterior side of the lesion. Vital signs were normal. On examination, there was a 2x2 cm painful, cystic soft tissue swelling with edema and erythema on the right earlobe, bilateral external auditory canals and tympanic membranes were found normal. There was no sign of anaphylaxis. Lab results revealed WBC:5800/mm³, hemoglobin:14,1g/dl, platelet:237.000/mm³, BUN:39 mg/dl, serum creatinine:0,9 mg/dl, ALT:23U/L, AST: 26U/L, sedimentation:6mm/hour, CRP:1.8mg/L. Spontan laceration on lesion was extended by using a lancet for drainage. Antibiotic therapy with amoxicillin/clavulanic acid and ciprofloxacin was begun empirically. Purulent fluid culture was performed and resulted positive for Staphylococcus aureus which is susceptible to amoxicillin. 7 days after antibiotic therapy tenderness, redness and swelling was gone. The patient was referred to dermatology department for patch test and results came positive for nickel and gold. The patient was informed about materials, domestic items or clothings that may possibly contain nickel or gold and adviced to avoid contact with the those causative substances.

CONCLUSION: Jewelry items such as ring, bracelet, necklace, earring, zippers or buttons of clothings, key chains, coins, metal chairs or tables, metal eyeglass frames and cooking pans which are commonly used in daily life may contain nickel. Detailed anamnesis should be obtained from patients when considering allergic contact dermatitis and all possible causes should be questioned.

An Atypical Presentation Of Helicobacter Pylori Infection: A Case Report

Oğuzhan Tezcan, Hülya Yıkılkan, Cenk Aypak, Derya İren Akbıyık, Süleyman Görpelioğlu
Department Of Family Medicine, Dışkapı Yıldırım Beyazıt Training and Research Hospital, Ankara, Turkey

INTRODUCTION: Helicobacter pylori(HP) infection is a major cause of gastritis and peptic ulcer disease and is a considerable source of morbidity and mortality. Proton pump inhibitors(PPIs) which are used in the treatment of HP infection have different pharmacokinetics and pharmacodynamics. CYP2C19 polymorphism may markedly affect the metabolism of PPIs. Homozygous CYP2C19*17 allele may cause 60-70% reduction in the area under the plasma drug concentration-time curve(AUC) of some PPIs such as omeprazole and lansoprazole by causing ultra rapid drug metabolism.

CASE: A 28-year-old woman visited our hospital with ongoing symptoms of nausea for several weeks. She denied heartburn, chest pain, acidic taste in her mouth, problems at swallowing, vomiting, diarrhea or constipation. Her weight was stable. She did not notice any blood in stool or dark stool recently. She reported that she had only taken pantoprazole 40 mg once daily for 6 weeks. At second visit to her doctor after 6 weeks, HP IgG serology test was performed and the result was negative. PPI administration was switched by her doctor firstly to lansoprazole(30 mg twice daily for 6 weeks), and then to rabeprazole(20 mg once daily for 4 weeks). Physical examination were normal. Rabeprazole relieved nausea partially but she was still symptomatic, thus we referred the patient for upper endoscopy. Endoscopic biopsy results showed metaplasia and HP infection. The patient was treated with 14 days therapy of amoxicillin, clarithromycin and rabeprazole. Three weeks after eradication therapy symptoms of patient disappeared. It is thought that the patient had CYP2C19 ultra-rapid metabolizer genotype.

CONCLUSION: In patients with HP infection nausea may be the only symptom. CYP2C19 polymorphism, especially in the presence of homozygous CYP2C19*17 allele ultra-rapid metabolizer genotype, may significantly reduce patients' response to the different PPI treatment options. In clinical practice, it should be kept in mind that lack of symptomatic response to PPI therapy does not always exclude the diagnosis of gastritis, peptic ulcer disease or HP infection.

Attention; It May Be Takayasu- A Case Presentation

Onur Öztürk¹, Gülsah Öztürk², Mustafa Yasin Selçuk², Fusun Artıran İğde², Mustafa Fevzi Dikici²

¹Atakum Community Health Center, Samsun, Turkey

²Department of Family Medicine, Ondokuz Mayıs University Faculty of Medicine, Samsun, Turkey

Takayasu Arteritis (TA) is a chronic large vein vasculitis characterized by elastic artery involvement such as aorta, main aorta branches and pulmonary arteries mainly. Yearly frequency is 2.6/million and mostly seen in 20-30 year-old females. Morbidity is related to arterial stenosis-related organ ischemia development. In this presentation, we will refer to TA in a muscle pain case.

20 year-old male patient applied to OMUTF Family Practice clinic in January 2015 with a two-month long back and shoulder pain. In physical examination, arterial blood pressure was 105/65 in the right, 90/60 mmHg in the left arm and systematic inspections were normal. Background and family risk factors were not present. Examination results were Hb: 10,7 g/dL, WBC: 9,20 x10⁹/L, PLT: 503 x10⁹/L, MCV: 79 fL, RDW: 15 %, Fe: 18 µg/dL, iron-binding capacity: 189 µg/dL, ferritin: 1219 ng/mL, CRP: 271 mg/L, Sedimentation: determined as 102 mm/h. The examination of the patient transferred to rheumatology was evaluated as waist ROM clear-painless, right shoulder ROM clear-painful, left shoulder ROM clear-unpainful, sacroiliac compression-/- and pelvis graphy was normal. The patient lost weight and was over-sweating in the last three months and there was a swelling in the right ankle two weeks ago and in the left ankle four days ago which disappeared. Diagnosis was TA as diffuse wall-thickening in bilateral CCAs and subclavian arteries in neck CT and also in ascending and descending thoracic aorta, brachiocephalic artery and subclavian artery on the right, CCA and subclavian arteries on the left in thorax CT and abdominal aorta wall diffuse thickening in upper-lower abdomen CT were noticed. The patient was discharged after starting Azathioprine 50 mg 3*1, Prednisolone 16 mg 3*1 and Lansoprazole 1*1 treatment. When he was controlled a week later, monthly control was recommended as there were no active complaints and laboratory results were normal.

⁵İzmir Katip Çelebi University, Faculty of Medicine, Department of Family Medicine

AIM: Persons who have anxiety symptoms such as chest pain and palpitation, often reason of admission to cardiology inpatient clinics, cardiology outpatient clinics and emergency services. Aim of this study is to determine level of anxiety symptoms of patients who admitted to cardiology clinics, to understand distribution of symptoms and research related factors.

MATERIAL-METHODS: This is a basic, sectional and descriptive study. Stationary population of this study was patients who were admitted to cardiology inpatient and outpatient clinics of Tepecik Educational and Research Hospital between 01.06.2013 and 31.07.2013. Sociodemographic findings questionnaire and Turkish version of Hamilton Anxiety Scale (HAS) were administrated to patients by interviewer. Statistical analyses of data were performed by SPSS 15.0 programme.

RESULTS: There were 101 participants in this study. Participants were between 18-65 years old. 50 of them were men (49,5%) and 51 of them were women (50,5%). Mean age of the participants was 48,49±11,59 (min:18, max:65). Mean of BMI's of participants was 27,41±4,88 (min:16.8,max:38.7). 79,2% of participants who were included to study had ischemic heart disease. Mean of HAS points of participants was 10,28±6,21 (min:0,max:26). 27 participants (%26,7) had no anxiety and their HAS scores were between 0 and 5 points. 49 (%48,5) participant's HAS scores were between 6 and 14 and they had mild or moderate anxiety and 25 participants had severe anxiety and their HAS scores were 15 and/ or higher 15.

CONCLUSION: Psychologic conditions affect coronary heart disease's progression negatively. Anxiety disorders are more common in patients who have coronary heart disease (CHD).

Right Valve Endocarditis And Hepatitis C Coupling

Derya Keten¹, Mustafa Azmi Sungur², Evrim Gülderen¹, Hamit Sırrı Keten³

¹Department of Clinical Microbiology and Infectious Diseases, Necip Fazil City Hospital Kahramanmaraş, Turkey

²Department of Cardiology, Necip Fazil City Hospital Kahramanmaraş, Turkey

³Department of Family Medicine, Kurtul Family Health Center, Kahramanmaraş, Turkey

BACKGROUND AND AIM: We aimed to increase the delicacy of the matter and inform the healthcare professionals by presenting a case who was addicted to intravenous drugs and developed complications due to this.

CASE: A 35-year-old male patient was initially diagnosed with pulmonary thromboembolism and treatment was planned. As the body temperature continued to be high on the fourth day of treatment, the patient was reevaluated and it was determined that he was addicted to intravenous drugs. Body temperature was 39°C. In the physical examination, there were bilateral rales at the basal parts of both lungs and a 3/6 systolic murmur was heard, which was more prominent in the tricuspid area; hepatomegaly and splenomegaly were detected. Laboratory parameters were as follows: leukocyte: 18,500/μL (neutrophil: 92.6%), CRP: 73 mg/l, AST: 73 U/L, and ALT: 57 U/L. In the pulmonary CT angiography, bilateral massive pleural effusion and multiple foci of abscess, the largest forming cavitation in the central part of the left lung, were detected. The blood culture showed methicillin-sensitive Staphylococcus aureus growth. In the echocardiography, hyper echogenic multiple mass images and cord rupture were detected in the tricuspid valve. Combined linezolid and meropenem therapy was

initiated. Hepatitis markers were determined as Anti-HCV (+), HCV RNA value of 776 065 IU/ml, and HCV genotype 3. Upon the follow-up of the patient, the vegetations disappeared. As the patient had an active HCV infection, the valve replacement surgery was left until after the treatment of the HCV infection.

CONCLUSIONS: It is important to struggle with drug addiction, which is gradually becoming widespread in Turkey and around the world, and their accompanying infectious risks. The high rate of HCV genotype 3, which is accompanied by drug addiction in the current study, presented the severity of this situation.

³Department of Family Medicine, Medical Faculty, Kahramanmaraş Sutcu Imam University, Kahramanmaraş, Turkey

⁴Department of Family Medicine, Kurtul Family Health Center, Kahramanmaraş, Turkey

⁵Department of Public Health, Medical Faculty, Gaziantep University, Gaziantep, Turkey

⁶Department of Psychiatry, Medical Faculty, Kahramanmaraş Sutcu Imam University, Kahramanmaraş, Turkey

BACKGROUND: Having a weak body appearance can affect the individual's body perception negatively, so may cause social anxiety. Due to this thought, in this study, we aim to determine the frequency of the social anxiety, in the individuals who are classified as weak for the body mass index (BMI).

METHOD: The 80 patients; who have not any known chronic and psychiatric diseases and classified as weak for the BMI, came to the diet polyclinics of Kahramanmaraş Sütçü İmam University Medicine Faculty Hospital and Gaziantep Şehit Kamil State Hospital between 06.12.2013 and 30.05.2014, have participated to this study. The control group was selected the 81 patients who have also not any known chronic and psychiatric diseases. At the first part of the survey form, there are the sociodemographic informations about the patients, like age, sex, economic income, job, length and weight. Liebowitz Social Anxiety Signs Measure is found at the second part.

RESULTS: 78 (%48.4) of the 161 patients who participated to the study were male, and the rest 83 (%51.6) patients were female. The mean age of the participants was 22.06±3.4 (min.=18, maks.=33). The mean of the total points of the whole participants taken from measure (scary point +avoiding point) was 55.11±19.35 (min.=1.0, maks.=104.0). Although the mean of total points of the Patient Group was 55.26±18.02, The Control Group's was 54.97±20.7. Any meaningful difference haven't detected between two groups' total points (p=0.925), also mean avoiding points (p=0.345) and mean scary points (p=0.430).

CONCLUSIONS: The negative body perception which formed by the weakness; likely the cause of social anxiety signs, should be estimated biopsychologically like a multi-faceted approach.

The Level of Knowledge, Attitude, and Behavior of Physicians Toward Organ Donation

Hamit Sırrı Keten¹, Oğuz Işık², Hüseyin Üçer², Derya Keten³, Özgür Ersoy⁴, Soner Ölmez⁵

¹Department of Family Medicine, Kurtul Family Health Center, Kahramanmaraş, Turkey

²Department of Family Medicine, Medical Faculty, Kahramanmaraş Sutcu Imam University, Kahramanmaraş, Turkey

³Department of Clinical Microbiology and Infectious Diseases, Necip Fazil City Hospital Kahramanmaraş, Turkey

⁴Department of Public Health, Medical Faculty, Cukurova University, Adana, Turkey

⁵Department of Family Medicine, Samsat Family Health Center, Adıyaman, Turkey

BACKGROUND: The aim of the present study was to determine the level of knowledge, attitude, and behavior of physicians toward organ donation.

METHOD: The present study was conducted in Kahramanmaraş province located in the Mediterranean region of Turkey. The study was conducted on physicians working at Kahramanmaraş Sütçü İmam University Medical Faculty Hospital, Necip Fazil State Hospital, and Family Health Centers between March 1st 2015 and June 9th 2015. A questionnaire was administered to gather sociodemographic data of the participants and their knowledge level, attitude, and behavior toward organ donation.

RESULTS: Of study participants, 160 (59.9%) were males and 107 (40.1%) were females, and the mean age was 34.91±6.98 years (min=24, max=55). Of participants, 33 (12.4%) had organ donation ID card and 234 (87.6%) did not have organ donation ID card. Of physicians, 128 (47.9%) showed willingness toward organ donation, 44 (16.5%) did not show willingness, and 95 (35.6%) had no idea. The participants were mostly aware of liver (n=253, 94.8%), kidney (n=249, 93.3%), cornea (n=245, 91.8%), and heart and heart valves (n=240, 89.9%) among all other donatable organs and tissues. Only 27 participants (10.1%) reported that physicians provided sufficient information about organ donation and transplantation. In addition, 170 physicians (63.7%) reported that organ donation was permissible in Islam.

CONCLUSION: The present study revealed considerable deficiencies in the knowledge about organ donation in physicians. In addition, the rate of registration for organ donation and the willingness toward organ donation was low in physicians. It was found that physicians did not have exhibit positive attitude to widespread acceptance of organ donation.

Evaluation of the Level of Knowledge, Attitude, and Behavior Toward Hepatitis B Virus (HBV) and Hepatitis C Virus (HCV) Infection in Barbers

Hamit Sırrı Keten¹, Hüseyin Üçer², Numan Güvenç², Derya Keten³, Celal Kuş², Mustafa Çelik²

¹Department of Family Medicine, Kurtul Family Health Center, Kahramanmaraş, Turkey

²Department of Family Medicine, Medical Faculty, Kahramanmaraş Sutcu Imam University, Kahramanmaraş, Turkey

³Department of Clinical Microbiology and Infectious Diseases, Necip Fazıl City Hospital Kahramanmaraş, Turkey

BACKGROUND: The aim of the present study was to evaluate the level of knowledge, attitude, and behavior toward HBV and HCV infection in barbers in order to make contribution to public health policies.

METHOD: The study included 165 barbers in Kahramanmaraş city center between March 3rd 2015 and June 10th 2015. The teachers were informed of the study and those who provided written consent were included in the study. A questionnaire that was prepared in accordance with the literature knowledge was administered to measure the level of knowledge about hepatitis B virus (HBV) and hepatitis C virus (HCV) infection in barbers.

RESULTS: The mean age of the participants was 27.33±10.87 (min=10, max=67) years. The total time spent in the occupation was 14.48±10.68 years (min=1, max=50). It was found that 78 barbers (47.3%) had taken the HBV vaccine. Of participants, 76 (46.1%) previously received training on HBV and HCV. Of these barbers, 117 (70.9%) were aware of HBV infection and 100 (60.6%) were aware of HCV infection. Of participants, 128 (77.6%) reported that hepatitis infections were contagious and 17 (10.3%) reported that hepatitis infections were not contagious, and 20 (12.1%) had no idea. Of the barbers, 101 (61.2%) reported that they had sufficient level of knowledge about the routes of transmission for HBV and HCV and 64 (38.8%) reported that they did not have sufficient level of knowledge. Of participants, 97 (58.8%) had taken the HBV vaccine to protect against the infection.

CONCLUSION: The study showed that barbers have insufficient level of knowledge about HBV and HCV infections. It is of particular importance to deliver training to barbers, which constitute an important occupational group for HBV and HCV carriage.

An HIV-negative Case With Kaposi Sarcoma

Mehmet Altuğ¹, Melahat Akdeniz²

¹Beyşehir 3rd Görgün Yavuz Family Health Center, Konya

²Akdeniz University, Department of Family Medicine, Antalya

INTRODUCTION:

Kaposi Sarcoma (KS) was originally described by Moritz Kaposi in 1872 as "idiopathic, multiple, pigmented hemorrhagic sarcoma of the skin". It has varying clinical course ranging from minimal mucocutaneous disease to diffuse organ involvement. It is categorized in 4 types as AIDS-related endemic type, KS in iatrogenically immunosuppressed patients, classic or sporadic type and Africa endemic type. Sporadic type KS is usually seen in Mediterranean or East Europe countries, in men over the age of 50.

The lesions of KS can be observed in skin, oral mucosa, lymph nodes and visceral organs. Majority of patients present with skin lesions. These skin lesions can start at any region but they typically condense at lower extremity, head and neck region. Lesions can be in the form of macules, papules, nodules or plaques.

THE CASE:

A 56 years old male patient presented to family health center with purple lesions that started at his toes nearly six months ago and spread to his feet later. In his physical examination, his overall condition was good, he had

diffuse lesions at his feet with uncertain borders. His medical history was featureless. According to his family history, his uncle had Kaposi sarcoma. The patient was consulted with cardiovascular surgery and and dermatology clinics with initial diagnoses of venous insufficiency, angio-dermatitis and Kaposi sarcoma. The patient was diagnosed with HIV-negative Kaposi sarcoma. This form of the disease is a vascular proliferation characterized with painless, purplish lesions that occur especially at lower extremities. There is no cure for the disease: however, antiviral and antineoplastic drugs can be used either alone or in combination.

CONCLUSION: As well as the commonly occurring diseases, rare diseases, also called the "zebra"-type diseases are also encountered in primary healthcare. Obtaining family history appropriately is useful for family physicians in making the diagnosis.

A Burkitt Lymphoma Case Presenting With Cervical Lymphadenopathy

Mehmet Altuğ¹, Melahat Akdeniz²

¹Beyşehir 3rd Görgün Yavuz Family Health Center, Konya

²Akdeniz University, Department of Family Medicine, Antalya

INTRODUCTION:

Lymphadenopathy (LAP) is a commonly observed finding during physical examination by family physicians. They are mostly benign and related to infections, responding to antibiotic treatment. Very few are related with cancers such as leukemia and lymphoma, and cancer metastases. The most common error related with LAP cases in Turkey is monitoring with repetitive antibiotic treatment. Cervical LAP can be caused by non-Hodgkin lymphoma (NHL) of the lymphatic system. NHL can arise in immunosuppressed patients and patients who receive immunosuppressive drugs. Burkitt lymphoma (BL) is a relatively rare and aggressive type of NHL. This disease mostly occurs in the face; 55-75% of the patients have involvement of the face. At the time of diagnosis, 30-50% of the patients have disease in its advanced stage. In Turkey, abdominal involvement is common, with a rate of 70%.

THE CASE:

A 32 years old female patient presented to the family health center with a painless mass that started below her mandible three weeks ago and enlarged gradually. Despite taking antibiotics for a week, the mass did not regress in size. In her physical examination, her overall condition was good, there was a mobile and painless lymphadenopathy, 3x4 cm in size at cervical region. The patient was consulted with ear nose throat clinic. An excisional biopsy revealed a diagnosis of NHL-Burkitt lymphoma and chemotherapy was initiated.

CONCLUSION:

Cervical LAP in adults is frequently encountered in family medicine practice. Presence of a lymphadenopathy in cervical region should be thoroughly investigated in all patients with consideration of the rare diseases, and differential diagnosis should be made. Recognition of the rare but vitally-critical diseases and appropriate management by family physicians is essential for treatment of the disease in its early stage.

Efficacy and tolerance of chronotherapy in hypertensive patients using a 24h AMBP measurement

Manuel José Viana¹, Ana Margarida Correia², Paulo Rui Pessanha², Susana Bertoquini⁴, Ana Iva Costa², Jorge Polónia³

¹Faculdade de Medicina da Universidade do Porto

²USF S. João do Porto – ACeS Porto Ocidental

³Hospital Pedro Hispano

⁴Faculdade de Psicologia e Ciências da Educação da Universidade do Porto

Background & AIM: To achieve the best antihypertensive drug administration time, day or night, evaluating the tolerance and efficacy of the drug administration in two schedules.

METHOD: Crossover, clinical randomized trial, including 32 hypertensive patients, aging 18-75 years old, taking at least one antihypertensive drug. Patients were divided in two groups, taking antihypertensive drugs by morning or by night. After six weeks, each patient was submitted to a 24h-ambulatory measurement of blood pressure (AMBP) and a 24h-urine test (microalbumin, creatinine, sodium excretion), switching the schedule to night and morning, respectively. After six weeks they were evaluated again (24h AMBP, urine test, quality questionnaire).

RESULTS: Morning drug administration data: 24h blood pressure (BP) - 125/76 + 12/9mmHg; daytime BP - 129/79 +12/9mmHg; nighttime BP - 116/69 + 15/9mmHg; morning BP peak, night fall BP and % of systolic BP of 17 + 18 mm Hg; 9 + 6%. Night administration data: 24h BP - 126/77 + 11/8 mmHg; daytime BP - 129/80 + 11/9 mmHg; nighttime BP - 117/69 + 15/9 mmHg; morning BP peak, night fall BP and % of systolic BP of 21 + 11mmHg; 9 + 7%. All of the results had a $p>0.12$. 87.5% of the urine samples were validated, with a medium salt intake of 16.25g/day.

CONCLUSION: There was not a statistical difference between the two schedules of administration (absolute BP, BP night fall, morning peak in the systolic BP). Salt intake was much higher than recommended by WHO. Each patient should be given an individual treatment, concerning patient's preferences.

Physician-patient relationship in the treatment arrangements, shared decision-making and patient satisfaction

Fatıma Yüce¹, Nilgün Özçakar²

¹Department of family medicine, Ankara university, Ankara, Turkey

²Department of family medicine, Dokuz Eylül university, İzmir, Turkey

Background & AIM: To expose patient-physician relationship, patients' thoughts and expectations about shared decision making in treatment process and relation between these topics and patient satisfaction.

METHOD: This is a cross-sectional study which participants were prescribed outpatients applied to primary care center (PCC) in 1-31 December 2013. A questionnaire including demographic information, patient' opinions and Turkish form of EUROPEP (Patients Evaluate General/Family Practice) scale was administered by the researcher face to face. SPSS 15.0 software, chi-square,t-test and ANOVA were used in evaluation of the data.p<0.05 was considered significant.

RESULTS: Of respondents 66.7% were female, 64.0% percent were high educated and the mean age 45.92±13.83. Totally 300 patients had prescribed in a PCC were included in the study. Preferences of patients in treatment organizing process were categorized in three groups. "shared decision making with the physician"(63,3%), "physician should decide"(32,0%), "physician should offer treatment options and I should decide"(4,7%). Total patient satisfaction scale mean score was 89,9±18,23. Clinical behavior subscale score was 64,80±13,43.Service organization subscale score was 25,15±6,80. Patient satisfaction scale scores were high who had asked ideas while had been prescribing and had given information about drugs and their side effects(p<0,05).

CONCLUSION: Shared decision making as patient centered approach in the process of treatment, affects positively the patient-physician relationship. This fact is also effective on satisfaction of patients in medical care. We believe that this approach which is quite valuable for medical care should have been adopted and participated in treatment process by the family physicians

Antibiotic use in children of mothers SITUATION AND KNOWLEDGE LEVEL

Ceren Karaman Kenesari¹, Nilgün Özçakar²

¹ceren KARAMAN KENESARI,Dokuz Eylül Üniversitesi,İzmir,Türkiye

²Nilgin ÖZÇAKAR,Dokuz Eylül Üniversitesi,İzmir,Türkiye

Antibiotic resistance is defined as; a certain strain of microorganism species not influenced by the antibiotic or antibiotic-sensitive strains which has become resistant with various resistance mechanisms. The wrong or unnecessary use of antibiotics is the most important factor that led to the rapid spread of resistant bacteria. In our study we aimed to evaluate the level of knowledge of mothers about antibiotics and contribute to limiting the unnecessary use of antibiotics.

Our research was carried out in November 2013 in Hatay, İzmir, health care center with number 24. Study data is collected by a face to face survey with mothers who have at least one preschool age child. Mothers were asked 6 questions including sociodemographic information, 6 questions related to knowledge about antibiotics, 10 questions related with behavior and also 3 questions to assess their attitudes. After the survey, there was brief information to mothers about the rational use of antibiotics. A month later, the mothers were surveyed by telephone with the same questionnaire. We viewed whether the difference between the two groups before and after the information was. Data were analyzed with SSPS 15.0. Mc Nemar analysis performed. P <0.05 was considered as statistically significant. We have created an awareness of the true knowledge of the intended use of antibiotics at the end of our study. The most important contribution of this study for mothers was the

improvement of knowledge about antibiotic side effects. By this study we aim to create awareness about the correct use of antibiotics and rational drug use. With brief information we have provided difference on certain issues. Rational antibiotic use is still an important health issue in our country.

Keywords: antibiotics, children, rational drug use

Reaching Out to the Youth of South-West Uganda: Sex-Education

Emma King¹, Clare Goodhart², Jonathan Graffy³, Sarah Uwimbabazi⁴

¹Tower Hamlets, London, United Kingdom

²Cambridge, United Kingdom

³Cambridge, United Kingdom.

⁴Bwindi Community Hospital, Uganda

Our aim was to test the feasibility of a church outreach sex-education programme for youth aged 14-20 years aimed at preventing HIV and teenage pregnancy. An additional objective was to collect data to ensure the programme is responsive to the needs of the target population.

We targeted 5 locations across 3 sub counties in south-west Uganda. The sessions included condom demonstrations and 3 health talks; "HIV", "Teenage Pregnancy" and "Periods and Personal Stuff".

Overall, 516 youths attended and 453 completed a baseline knowledge quiz. The results of the quiz demonstrated which topics were best and least understood. 81% knew that HIV could be treated but 51% did not know about the risk of mother to child transmission. 39% thought that contraceptives could cause permanent infertility.

Throughout the sessions, anonymous written questions were invited and answered. These questions indicate the concerns and misconceptions of the target group.

A feedback questionnaire asked participants to write two learning points and suggest one thing they wished we had taught them. This gave us insight into what they had gleaned from the sessions and the topics we had missed, such as more about contraception and other STIs.

This pilot programme acted as a thorough needs assessment for providing sex-education to the target group. The data collection tools embedded within the programme will continue to help it respond to the needs of this group. This approach is relevant to similar programmes in a multitude of settings.

Keywords: Youth, sex education
