Sarcoma Giant Gluteal. A case report

Rosa M^a Palacios Fort, Beatriz Soria Navalón
CSI Campello, Department of health 17 San Juan, Alicante, Spain

BACKGROUND: Soft tissue sarcomas (STS) are malignant tumors derived from connective tissue. They may appear in any part of the body, although they are more common in the legs and arms. They constitute about 1% of the total number of malignant tumors, and are responsible for 2% of deaths due to cancer. The annual incidence in adults in Europe is 14,000 new cases. They are slightly more common in men and can be seen in all ages with higher incidence between 40 and 60 years.

METHOD: 62 year old woman with a history of bilateral knee osteoarthritis notes that in September of 2014 the appearance of a lump in her buttock that hurt, but no reference it to her family doctor until December 2014 where the mass is already very large. She is urgently sent for an ultrasound: heterogeneous mass, with center anechoic and hipoechoic periphery. Lobed outlines well defined. Possible sarcoma for which is send her urgent to Traumatologist who applies for biopsy, Abdominal CT, bone scan, MRI of the pelvis that confirms the sarcoma (18 x 15 x 12 cm) plus lymph nodes in left hemi pelvis, and chest CT that shows pulmonary metastases.

RESULTS: Pathology: necrotic mesenchymal spindle cell tumor, compatible with Sarcoma NOS of high-grade. Nuclear pleomorphism: moderate. Immune: Vimentin: positive. S-110, Desmin, Actin, EMA, CK, CD34: negative. Index of cell proliferation Ki67 (MIB1): 40%.

Diagnosis: Sarcoma NOS left gluteus G3cT2bN0M1 (lung). Chemotherapy and local tumor surgery. Bad prognosis.
CONCLUSIONS:

Despite the low incidence of the STS we must investigate any suspicious mass since the prognosis will depend on histological grade, size, location in the tissue and in the organism and the presence or absence of metastases.

Acute bacterial meningitis. A case report

Beatriz Soria Navalon, Rosa M^a Palacios Fort
CSI Campello, Department of health 17 San Juan, Alicante, Spain
BACKGROUND AND PURPOSE

Acute bacterial meningitis is an infectious disease that causes inflammation of the leptomeningeals, the surrounding tissue and spinal cord.

The most common causes of meningitis are viral infections that usually get better without treatment. However, bacterial infections are extremely serious and an important cause of morbidity and mortality. Hence the importance of rapid diagnosis to start an immediate antibiotic therapy.

METHOD

65 year old woman with Diabetes Mellitus, Hypertension, Dyslipidemia and Hypertensive heart disease, went to the Emergency Health Center for a holocranial headache, a fever of 38 degrees that lasted for 12 hours and a disorientation in space and time with agitation. She has also presented vomiting and nausea.

Physical examination: Regular general condition, dyspnea at rest, sweaty.

Blood pressure: 210/96; Heart Rate: 110 bpm; Oxygen saturation: 90%

Conscious and disoriented in space and time with preserved language. Psychomotor agitation. No meningeal irritation. Isochoric and normorreactivities pupils. Preserved cranial nerves. Strength and sensitivity not evaluated because a bad patient cooperation. Romberg and march not evaluated. Reflex Babinski bilateral flexor.

Patient was sent to the emergency department of the hospital to rule out infectious disease:

Additional tests:

- Analysis: Leukocyte 19.3 10e9 / L.
- Cranial CT: frontal cortical atrophy.
- Analysis of Cerebrospinal Fluid: glucose 265 mg / dl, proteins 577.9 mg / dl, leukocytes 8032 mm3, Polynuclear 92, 3%.

RESULTS

Acute Bacterial Meningitis

CONCLUSIONS

Broad spectrum antibiotic therapy was started immediately and the patient was sent to Neurology, improving neurologically during her stay at the hospital.

The intravenous antibiotic therapy with rapid diagnosis has proven effective in lowering mortality and reducing subsequent neurological consequences.

Keywords: bacterial meningitis, meningitis, meningitis treatment

Consequences of not anticoagulated Atrial Fibrillation in a patient with vertigo resistant to medical treatment. A case report

Beatriz Soria Navalon, Rosa M^a Palacios Fort

CSI Campello, Department of health 17 San Juan, Alicante, Spain

BACKGROUND AND AIMS: Atrial fibrillation (AF) is more common cardiac arrhythmia in the clinical practice, increasing five times the risk of stroke and thromboembolic attacks. The mortality rate is double that of patients with sinus rhythm. Antithrombotic therapy reduces the risk of stroke and AF related deaths.

METHOD: A 78-year-old woman that presents Dyslipidemia, hypertension and non-anticoagulated atrial fibrillation. Independent for activities of daily living. The usual medical treatment is acetylsalicylic acid 100mg / 24 h, Flecainide 100mg / 24 h, Nimodipine 30mg / 24 h, came to the emergency department of the Healthcare Centre for dizziness that lasted for a few hours of evolution. No sensation that objects in the environment are moving, with nausea and vomiting together with gait instability and no tolerance for standing. She has no other symptomatology.

The general condition is not good. Eupneic at rest.

Blood pressure: 180/90, temperature: 36,2^o; Glucose: 68mg/dl.

Conscious and oriented to three areas with preserved language. Campimetry by confrontation is normal. No horizontal or vertical nystagmus. Preserved cranial nerves. No meningeal irritation. Maintained strength and sensitivity. Cutaneous-plantar reflexes in flexion. She does not show dysmetria. Negative results in the Romberg test. Ataxic gait.

Relevant complementary tests:

- Analytical test: glucose 152mg/dl, PCR 4, 12mg/dl.
- Brain tomography: low attenuation level in the lower back part of the left cerebellar hemisphere that suggests an ischemic process of the posterior inferior cerebellar artery (PICA) territory. No bleeding.

RESULTS

Ischaemic cardioembolic brain infarct in the left inferior cerebellar artery territory.

CONCLUSION

The patient progressed positively being capable of walk autonomously. In addition, it was recommend to suspend the Acetylsalicylic Acid and start with Apixaban 2.5 mg every 12 hours.

We have to remember that central vertigo is a cause of cerebellar ischaemic as a consequence of not anticoagulated AF.

Iliofemoral-popliteal deep venous thrombosis – a diagnosis not to forget

Iva Lopes¹, Joana Leça²

¹UCSP de Macedo de Cavaleiros

²USF Terras do Ave

BACKGROUND: Deep venous thrombosis (DVT) and pulmonary embolism are manifestations of a single disease named venous thromboembolism. DVT is the presence of a thrombus in one of the deep veins, most commonly involving the leg or arm. Usually affects patients who are over 40 years old, obese, bedridden, who have had major operations or have hypercoagulable states. The common presenting features of painful, tender, swollen limb which is warmer than the other limb are non specific.

AIM: To describe a case of DVT in a young woman.

METHOD: Review of medical records.

Case description: Young female of 23 years old, healthy, medicated with oral contraception, with 5 hospital visits within a month. First presented with complains of pain in the right popliteal region, without other signs of inflammation, which she associated with her gym workout. Then appealed twice for chest pleuritic pain without dyspnea, and a fourth time for pain at right iliac fossa. During these visits, she was seen by Family Physicians, Orthopaedics and General Surgeons, and all discharged the patient with muscle relaxants, tranquilizers and anti-inflammatory drugs. At the fifth visit, in addition to pain on the right lower limb, she had unilateral swelling. It was suspected thrombophlebitis of the right lower limb and the patient was transferred to the Vascular Surgery Team. Venous ultrasonography confirmed the presence of right iliofemoral-popliteal DVT.

CONCLUSION: Although healthy and young people aren't usually affected by DVT, we have to be aware that it can happen at any age. It can be difficult to diagnose, and in most cases requires a high index of suspicion. It took about 1 month and several observations by different physicians to properly diagnose this patient and it could have turned into a more severe case as she could have had a pulmonary embolism.

A nightmare of a family physician; Headlice; a case report and literature review

Duygu Ilke Yıldırım, Ayşe Selda Tekiner, Ayşe Gülşen Ceyhun Peker, Mehmet Urgan

Department of Family Medicine, Ankara University, Ankara, Turkey

Head lice commonly alert feelings of disgust, detestation, anger, and shame among parents and patients. Head lice infestation, or pediculosis capitis, caused by *Pediculus humanus capitis*, is a common health concern especially in childhood. In the US, where pediculosis capitis is the most prevalent parasitic infestation of children, 6 to 12 million people are affected every year. *Pediculus capitis* remains a health problem in schoolchildren also in Turkey. In addition to improvement in socioeconomic status, collaborative and participation efforts among physicians, nurses, teachers, and parents are necessary to maintain effective epidemiological surveillance and provide treatment.

Our case report may be the unique example of an infected family physician on her pediatrics emergency duty. 29 years old family medicine resident who has assigned pediatrics rotation; infected by head lice because of a patient. Scalp pruritus is her cardinal symptom, especially at her preauricular and occipital region. Pruritus with impetiginization prompted her husband who is also a doctor; orthopaedics surgeon. He had seen lice and viable nits. All close contacts also examined. Proper application of topical pediculicidal agents', chiefly permethrin lotion and wet combing with a fine toothcomb were chosen as medical management of that infestation. Spraying or fogging home with insecticides or pediculicides was not applied.

After a big struggle; a succesful treatment has obtained. This case will be a very useful sample for the doctors who are examining the childhood profile to protect theirselves from the parasites.

Attention to Diabetes in Children! Diabetic Ketoacidosis: A Case Report

Aslıhan Çiflik Bolluk, Candan Kendir Çopurlar, Vildan Mevsim
Department of Family Medicine, Dokuz Eylül University, İzmir, Turkey

Introduction

Family physicians are the point of first contact and manage conditions that may present early and in an undifferentiated way. The prevalence and incidence of illnesses is different from that which appears in a hospital setting and serious disease presents less frequently in general practice than in hospital.

In childhood, infections are the first reasons of diabetic ketoacidosis (DK) both initial diagnosis of diabetes and diabetic patients under treatment.

In this case report, a DK case that is initially undiagnosed will be discussed.

Case presentation

8 years-old girl, had complaints of chills in hands and feet, paleness on face and fatigue which started two days ago. The patient with complaints of frequent breathing and vomiting applied to family medicine health care centre. The family physician she is registered was off duty and for that reason she took health care by another doctor in health centre. She had diagnosis of otitis and give a prescription. She was called for control visit the next day. Because when she arrived home, her complaints of vomiting and breathing were increased, the patient applied to emergency service and had a chest x-ray, it was interpreted normal. She was discharged. When the patient arrived home, her shortness of breath has increased and pupils were dilated and applied to emergency service again. When her fasting blood glucose was measured, it was 382 mg/dl. Beside Kussmaul breathing, there was not additional symptom in her physical examination. She was diagnosed DK and treatment started.

Conclusion

Incidence and prevalence of type 1 diabetes and DK in children are rare, diagnosis of this disease is difficult in general practice. When the family physician find out infection and respiratory distress in children patient, he should think of the diagnosis of diabetes and measure blood glucose level.

Introduction of Stroke code in an emergency department

Pedro Guijo González, José María Fernández González, Hector Leonardo Lugo Ramos, Juan Jesús Rodríguez Vallejo
Hospital Jerez de la Frontera, Spain

The Acute coronary Syndrome is a time dependent illness whose prognostic is related to the precocity of its detection and treatment. The objectives of the present study are to analyze the experience of the implantation of the Stroke Code and describe the features of the patients that have been treated.

Materials and methods.

Prospective and observational study in a sanitary area of a Second level hospital. The time of study was of 7 months. It included patients with acute coronary syndrome with ST elevation in whom the Stroke code was activated.

The variables included were age, sex, mode in how the attention was demanded, treatments applied and clinical results. The variables were analyzed with SPSS 22 (statistic program).

Results

In 72 times was the Stroke code activated, 30% of them treated with fibrinolysis and 70% of them with primary angioplasty. In 30,6% of the patients treated with fibrinolysis, 86% of them were males, medium age 59,3. Of those, 9% arrived to the hospital by themselves whereas 91% rest needed help from the Extra-hospital EM service. The service showed in our study an effectiveness of 51% whereas the 49% rest needed a Rescue angioplasty.

The 69,4% of the patients who were treated with primary Angioplasty, 88% of them were males, medium age 62. Of those, 38% arrived without help whereas the rest (62%) required the EM Service.

Conclusions

In our study, the implantation of the Stroke Code has increased the number of patients treated with Primary Angioplasty, improving at the same time the clinical aspects at its arrival to the hospital. Moreover, the Stroke code was activated mostly in young patients with cardiovascular risk antecedents.

Fibrinolysis, a real outpatient alternative

Pedro Guijo Gonzalez, José María Fernández González, Juan Jesús Rodriguez Vallejo, Hector Leonardo Lugo Ramos
Hospital Jerez de la Frontera, Spain

The aim of this study is to analyze and compare times of performance between Primary Angioplasty and Fibrinolysis.

We pretend to underline the importance of the knowledge and results of the Fibrinolysis therapy due to the benefit it gives to the patient.

Method

We analyze during a period of 6 months, a total number of 72 Stroke Code patients in a Second level hospital. We compare Fibrinolysis and Primary angioplasty by analyzing times between first medical contact and appliance of the treatment and time between pain and treatment. We also analyze the need of rescue in patients treated with Fibrinolysis.

Results

Medium age was of 60 years, 88% of them were males whereas 12% of them were women.

The time between pain and appliance of Fibrinolysis was averaged 120 minutes, median of 97 minutes. Time between first medical contact and appliance of fibrinolysis was averaged 53 minutes, median of 47 minutes. The total effectiveness of fibrinolysis was in 50% of the patients, medium aged 59 and 86% of them male sex.

Primary angioplasty was applied 69,4% of the times, patients medium aged 62 and 88% of them male sex. Time between pain and appliance of the therapy was averaged 220 minutes, median of 195 minutes. On the other hand, time between first medical contact and Angioplasty was averaged 128 minutes, median of 110 minutes.

Time between initiation of pain and first medical contact was averaged 91 minutes, median of 46 minutes.

Conclusions

Fibrinolysis has an effectiveness of 50% which implies the removal of the obstruction in less time with the subsequent decrease in posterior morbimortality.

If we apply Fibrinolysis we get to a decrease in performance time not only since the beginning of the pain but also since first medical contact to the appliance of the therapeutic procedure.

Patient and investigator ratings of flurbiprofen 8.75 mg spray as a treatment for sore throat

Marc Russo¹, Fred De Looze², Mark Bloch³, Barney Montgomery⁴, Gary Smith⁵, Adrian Shephard⁵, Sue Aspley⁵

¹Hunter Pain Clinic, Newcastle, NSW, Australia

²AusTrials Pty Ltd, Sherwood, QLD and School of Medicine, University of Queensland, Brisbane, QLD, Australia

³Holdsworth House Medical Practice, Sydney, NSW, Australia

⁴Optimal Clinical Trials, Auckland, New Zealand

⁵Reckitt Benckiser Healthcare Ltd, Slough, UK

BACKGROUND & AIM: Patients with sore throat who visit a healthcare professional are looking for an effective treatment to reduce their symptoms. Using traditional pain measurements, we evaluated flurbiprofen 8.75 mg spray as a treatment for sore throat, from the perspective of the patient and the investigator. **METHOD:** This randomised, double-blind, placebo-controlled, multicentre study enrolled patients with recent onset (≤ 4 days) sore throat due to an upper respiratory tract infection. Patients took one dose of flurbiprofen 8.75 mg cherry mint flavoured spray or placebo spray without added flavour or odour and were instructed not to re-dose for 6 hours. At 3 hours post-dose patients completed the patient satisfaction scale (SATIS) and the global evaluation of the study medication (GLOBAL). The investigator also completed the practitioner's clinical assessment of drug efficacy scale (CLIN). All adverse events (AEs) were recorded. **RESULTS:** 505 patients (mean age 25.6 years, 44% female) were randomised (flurbiprofen spray n=249, placebo n=256). For the SATIS evaluation, 132/248 (53.2%) of patients reported they were either 'satisfied, very satisfied or extremely satisfied' with the study medication in the flurbiprofen spray group compared with 83/254 (32.7%) in the placebo group ($p < 0.0001$). For the GLOBAL evaluation, 222/248 (89.5%) of patients reported the study medication as 'fair, good, very good or excellent' in the flurbiprofen spray group compared with 178/255 (69.8%) in the placebo group ($p < 0.0001$). For the CLIN evaluation, investigators reported the study medication as either 'fair, good, very good or excellent' for 203/238 (85.3%) patients in the flurbiprofen spray group and 166/248 (66.9%) in the placebo group ($p < 0.0001$). No significant differences in AEs were reported between treatment groups over 6 hours (flurbiprofen 6.8%, placebo 3.1%; $p = 0.061$). **CONCLUSIONS:** Flurbiprofen 8.75 mg spray is an effective treatment for sore throat and is rated favourably by patients and healthcare professionals.

Funicular Myelosis: Regarding a case

Giovanna Lovatón¹, Jorge Hidalgo², Angeles Ortega¹, Celia Quiroz¹

¹Consorti Sanitari de Terrassa

²Hospital Mutua de Terrassa

Case Presentation

A 50-year-old patient with no allergies and no toxic habits, presents in July of 2013, one year of tingling fingers that was studied as carpal tunnel syndrome finally discarded. After a few weeks, symptoms as tingling feet were described with no electromyographic alterations. Finally, instability and heel gait were observed. He was derived to rapid diagnosis unit in our reference Hospital.

The patient had a medical relevant history of hypertension, anxious depressant syndrome, both, in medical treatment since 2012. Once before, he presented numbness in palms that were described as symptoms related to anxiety.

Physical examination: mild paresis of the left lower limb, hyperreflexia of lower limbs, ataxic gait in heels with increased support base and altered proprioception.

Brain CT scan and MRI were normal.

Spinal MRI showed hyperintense lesions in the posterior columns, most evident at the cervical spine, which extends the entire length of the spine, without contrast enhancement.

Fibrogastroscopy and biopsy showed atrophic gastritis without *Helicobacter Pylori*.

Blood test: megaloblastic anaemia with decreased serum vitamin B12 levels (22.14 g/L [141-489]) confirmed diagnosis of funicular myelosis.

The patient was treated with intramuscular vitamin B12 three times a week for one month, then, once a week for two months and finally once a month.

After three months during monitoring visits, ataxic gait has improved, but not proprioception.

After one year the physical examination is normal, although patient describes dysesthesia at the column.

Discussion

Funicular myelosis is considered to be the main neurological syndrome in vitamin B12-deficiency.

Clinical and functional symptoms of funicular myelosis and chronic gastritis in patients with B12-deficiency anemia, are most subjective, includes paresthesia, limb weakness, while objective ones includes impaired limb sensitivity. These findings are often related with pathologic changes in gastric mucous membrane.

Keywords: Funicular Myelosis, B12-deficiency, chronic gastritis

Applicant With Acute Kidney Failure Abdominal Aortic Aneurysm Thrombosis

Ihsan Ateş¹, Nisbet Yılmaz¹, Ömer Akca², Iskender Bülbül², Adem Bahadır², irfan Şencan², Adem Özkara³

¹Department of Internal Medicine, Ankara Numune Training and Research Hospital, Ankara, Turkey

²Department of Family Medicine, Ankara Numune Training and Research Hospital, Ankara, Turkey

³Department of Family Medicine, Çorum Hitite University, Çorum, Turkey

Acute thrombosis abdominal aortic aneurysm (AAA) is a rare complication that can be progressed with paralysis, lower limb ischemia, acute renal failure (ARF), mesenteric ischemia, and aortic aneurysm. We have present applicant with ARF and acute thrombosis case which progress related to infrarenal abdominal aorta aneurysm. Sixty-five years old male patient applied to emergency service, began four hours before sudden loss power and inability to walk. He has got cure lung cancer and hypertension in his biography. On physical examination; vital symptoms are stabil. Heart and respiratory examination were normal but abdominal examination wasn't effective because of obesity. In laboratory, hemogram normal, urea 83mg/dL, creatinine: 5.9mg/dl, AST 744IU/L, LDH: 2222U/L, CK Total: 82700U/L. In renal artery doppler: in abdominal aorta origin of right renal artery approximately 23mm, distal to origin of left artery 19mm approximately 10cm segments, mural thrombus situated on its wall AP diameter reaching 49mm fusiform aneurysm was detected. In CT angiography: in abdominal aorta starting distal about 1.5cm to renal artery ostial, approximately 10cm segment, measured 57x51mm sized in the widest part, measured in thickest part of lumen 22mm, aneurysmal dilatation that has mural thrombus which surrounding aorta was observed. Stent was placed to abdominal aortic part by interventional radiology and anticoagulation therapy was started. 4 weeks after his hospitalization kidney function tests were completely regressed and the patient mobilized.

Abdominal aortic aneurysm in patients with acute aortic aneurysm thrombosis is a rare complication that can be seen in 0.7-2.8%. In the literature, it is emphasized that mortality is over 59%. In the cases that admit with ARF when AAA thrombosis is detected and treated, it is mentioned that the improvement of kidney function of patients in short term. As a matter of fact in our case, after detected AAA thrombosis then stent operation ARF has improved in a short term.

Keywords: Acute thrombosis abdominal aortic aneurysm, acute renal failure, acute thrombosis

P-0258

Rhabdomyolysis Case based on Hypothyroidism

Ihsan Ateş¹, Nisbet Yılmaz¹, Ömer Akca², Adem Bahadır², Iskender Bülbül², İrfan Şencan², Adem Özkara³

¹Department of Internal Medicine, Ankara Numune Training and Research Hospital, Ankara, Turkey

²Department of Family Medicine, Ankara Numune Training and Research Hospital, Ankara, Turkey

³Department of Family Medicine, Çorum Hittite University, Çorum, Turkey

Muscle involvement in hypothyroidism is a rare complication. These patients are often present with decreased muscle mass, cramps and myalgia. With these clinical symptoms increasing muscle enzyme (creatinine kinase, aspartate aminotransferase, lactate dehydrogenase..) suggests the rhabdomyolysis table. Rhabdomyolysis based on hypothyroidism is not a common condition. In these cases, acute kidney failure based on rhabdomyolysis may also be seen. In this case report, a case which detected rhabdomyolysis based on deep hypothyroidism will be discussed.

Seventy-two years old male patient applied to our clinic with the complaints of increasingly widespread muscle pain, muscle weakness and leg cramps. The patient who had total thyroidectomy based on multinodular goiter did not proceed using levothyroxine after surgery. The patient's vital signs during the application; fire: 37.3°C, pulse 55 / min, BP: 130/90 mmHg, respiratory rate 13 / min. On physical examination, cardiac and respiratory were normal, dry skin, decreased turgor tone, bilateral lower extremity trace edema and palpation tenderness in the legs were available. In examined laboratory findings; Urea: 50 mg / dL (17-43), creatinine: 1.3 mg/dL (0.5 to 1.2), AST 94 IU/L, LDH 796 U/L, CK Total: 4370 U/L, Troponin I: 0.021 ng/ml, CK-MB: 8 U/L. TSH: >100 µIU/ml, FT4: <0.15 ng/dL (0.61 to 1.12), St3: 1.04 pg/ml (2.5 to 3.9). 0.6 mcg/kg of levothyroxine treatment was started considering that the patient has rhabdomyolysis based on deep hypothyroidism.

Rhabdomyolysis myoglobin is characterized by muscle cells element escaping into the circulation which include electrolyte and sarcoplasmic proteins (creatinine kinase, aldolases, lactate dehydrogenase, alanine aminotransferase and aspartate aminotransferase) (2). Rhabdomyolysis(3) also known as injuries, crush syndrome, may also present rare with hypothyroidism while it is a situation usually seen after major trauma. Rhabdomyolysis based on deep hypothyroidism, developed in this patient who did not proceed using levothyroxine after total thyroidectomy in this case report.

Keywords: Rhabdomyolysis, Hypothyroidism, creatine kinase

Medical Management of Patients Admitted To Family Medicine Clinic with Upper Respiratory Tract Infections Symptoms

Zehra Aslan Aydoğdu, Elif Altunbaş Ateş, Turan Set

Department of Family Medicine, Karadeniz Technical University, Trabzon, Turkey

Background&AIM: Upper respiratory tract infection(URTI) is one of the most experienced diagnosis by family physicians. Although majority of these are viral diseases; they treated with antibiotics. In this study, patients admitted to family medicine clinic with URTI were evaluated as symptomatic or antibiotic treatment approaches.

METHODS: Our study was performed between January-March 2015 period as a cross-sectional study. We evaluated 95 people (consisting of 46 women and 49 men) with the symptoms of URTI. We included patients who are 18 years and older. We performed a short questionnaire which consists of patients age, gender, symptoms, time elapsed since the onset of symptoms, finding and treatment. The data were analyzed.

RESULTS: The median age of patients was 23 (minimum 18- maximum 60). There was no difference between mean age by gender (p:0.455). Complaints in order of frequency were cough, sore throat, fatigue, nasal drip, headache, sputum, fever, postnasal drip and other complaints (Table 1). %69.5 of the patients was treated with symptomatic

drugs and %30.5 with antibiotics. There was no significant difference between the kind of treatment and time elapsed since the onset of symptoms ($p>0.05$).

DISCUSSION: URTI are the most common reasons among patients consulting a physician. While usage of antibiotics ranks fourth in the world, ranks first in Turkey. While in one study which made with examining physician diagnosis of prescriptions of URTI written by general practitioners, antibiotic prescribing rate is 73.8%, in our study this rate is 30.5%. This result shows positive effect of being specialized; but needs to be evaluated with large series. May be reason of writing less antibiotics is detailed history and physical examination. The reason why antibiotics prescribed less in Family Medicine Department could be detailed history and physical examination.

CONCLUSION: Detailed history and physical examination is essential in family medicine. The use of algorithms such as McIsaac (Table 2), Centor criteria's provide convenience in making clinical decisions.

Clinically meaningful relief of severe sore throat with flurbiprofen 8.75 mg lozenge

Bernard Schachtel¹, Adrian Shephard², Sue Aspley², Gary Smith², Tim Shea³, Kathleen Sanner¹, Laurie Savino¹, Emily Schachtel¹

¹Schachtel Research Company, Jupiter, FL, USA

²Reckitt Benckiser, Slough, Berkshire, UK

³Reckitt Benckiser, Parsippany, NJ, USA

Background & Aim

Patients with sore throat, especially those with more severe symptoms and findings, are the patients who frequently expect antibiotic treatment. However, most of these sore throats are of viral aetiology. Furthermore, the practitioner may be unsure if a non-antibiotic treatment can provide clinically meaningful relief for these patients. One standard for assessing this endpoint is the double-stopwatch (DSW) methodology (Desjardins, Clin Pharmacol Ther 1996;59:130). Using the structure of a randomised, double-blind, placebo-controlled DSW trial, we evaluated the median time to meaningful relief (TMR) by treatment with flurbiprofen 8.75 mg lozenge in patients with relatively severe sore throat.

Method

Adults with sore throat were evaluated for evidence of pharyngitis on the Tonsillo-Pharyngitis Assessment (TPA), an index of seven objective indicators of pharyngeal inflammation. Patients rated the severity of throat soreness on the 0–10 Sore Throat Scale (STS). Patients with relatively severe sore throat (STS >7) and relatively severe pharyngitis (TPA >7) were randomised to suck one flurbiprofen or placebo lozenge. Two stopwatches were started when patients took their assigned lozenge. Patients depressed one stopwatch when they first perceived any relief and the other when they experienced meaningful relief. The TMR was measured for both treatment groups.

Results

There were 51 patients evaluated (flurbiprofen n=43, placebo n=8) with STS >7 and TPA >7. For flurbiprofen-treated patients, TMR was 47.2 minutes, significantly better than placebo (p<0.05). TMR could not be calculated for the placebo group because 87.5% of placebo-treated patients did not experience meaningful relief.

Conclusion

Flurbiprofen 8.75 mg lozenge provides meaningful relief to patients with relatively severe sore throat. Because these are the patients most likely to seek antibiotic treatment, practitioners should consider recommending a treatment such as flurbiprofen 8.75 mg lozenge as many of these patients will experience meaningful relief and unnecessary antibiotics can be avoided.

Meningioma, guilty or just a random finding?

Sara Matos Moreira, Gabriela Silva Poças, Luis Monteiro Magalhães
USF Leça, Unidade Local de Saúde de Matosinhos, Matosinhos, Porto, Portugal

BACKGROUND: 45 year old Woman, smoking history; dyslipidemia; persistent anxiety with hypochondriacal traits; depressive syndrome; mixed urinary incontinence; fibrocystic breast disease; multinodular goiter (hemithyroidectomy); endometriosis (adnexectomy).

Medication: Trazodone; Mirtazapine; Alprazolam; Simvastatin

AIM: Reflection on the clinical practice aiming to improve the health care's quality.

METHOD: Case report.

RESULTS: Recurrent fainting with four months evolution, when lifting the arms above shoulder level, caused by hyperextension of the upper limbs. Without loss of consciousness. Summary neurological exam without changes. Asked for an opinion to the Neurology, which suggested performing Doppler Carotid for exclusion of thoracic outlet syndrome. The examination revealed no relevant clinical changes.

By persistent complaints of sporadic fainting, 15-20 episodes since start, with variable intensity and frequency, is referred to Neurology, which requested tests to exclude vascular, structural and epileptic causes.

On the day of Computed Tomography (CT) skull-brain scan was referred to the emergency for it was found an occupying lesion of extra-axial space, frontobasal and right temporal lobe, suggestive of sphenoid wing meningioma, with extensive vasogenic edema and mass effect. Right lateral ventricle and third ventricle collapsed and subfalcine herniation. Left ventricular dilation presenting bulging contours indicating hydrocephalus in formation. Contacted the Neurosurgery, which by looking at imaging findings and despite the patient being asymptomatic gave order for hospitalization for further macroscopic resection of the meningotheial meningioma.

CONCLUSIONS: The differential diagnosis of this clinical case is most likely of vascular etiology. However, ruling this etiology out and assuming other entities, such as epilepsy, it is excluded due to clinical and normal electroencephalogram.

Other hypothesis could be structural pathology, which is why we asked for CT skull-brain scan to confirm the diagnosis.

An evidence-based overview with a primary care perspective on piriformis syndrome causing sciatica

Kevork Hopayian

Norwich Medical School, University of East Anglia, Norwich England

Background and Aim

Nerve root compression by a herniated intervertebral disc or spinal canal stenosis has long been the disease model for sciatica. A cause is not found in a significant proportion of cases. Entrapment of the sciatic nerve, piriformis syndrome (PS), as a cause remains controversial yet potentially could explain many cases for which no cause is found. This study was designed to provide an overview of the evidence on the prevalence, diagnostic criteria and treatment of PS.

Method

Medline, Embase, CINAHL and AMED databases were searched using a broad search strategy. All types of observational and intervention studies were eligible for inclusion. Study heterogeneity was too great for pooling so a descriptive synthesis was planned. The quality of studies was evaluated by assessment of risk of bias.

Results

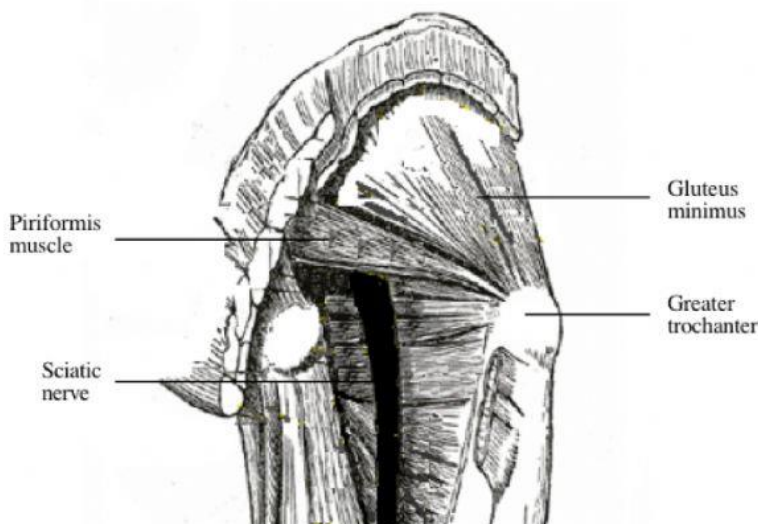

The number of related publications has multiplied in the past three decades. Modern imaging studies provide strong evidence for the condition. Only two out of 23 reviews have used systematic methodology. The quality of primary studies was generally poor to moderate. Moderately strong evidence suggests that PS accounts for 6 to 10% of sciatica cases. Moderately strong evidence suggests that diagnosis can be made on clinical grounds using techniques for localising soft-tissue disorders already familiar to family physicians. Weak to moderate evidence exists for the effectiveness of physiotherapy and injection therapy. Before-and-after studies provide evidence for surgical release in selected cases.

Conclusions

PS is a real entity. While it may be uncommon, it may form a significant proportion of unexplained cases of sciatica. The evidence suggests that clinical diagnosis by family physicians is feasible and that appropriate treatment in the form of physiotherapy can be provided in primary care. Future research should be directed at establishing the accuracy of diagnosis and improving the quality of studies of treatment.

Evaluation of Corrosive Esophagitis and Importance of Preventive Medicine

Aysenur Alper Gurz¹, Fusun Artiran Igde¹, Yasemin Bilgin Buyukkarabacak², Aysen Taslak Sengul², Selcuk Gurz²

¹Department of Family Medicine, Ondokuz Mayıs University, Samsun, Turkey

²Department of Thoracic Surgery, Ondokuz Mayıs University, Samsun, Turkey

Background&AIM: Accidents are one of the main factors that shorten healthy life. All over the world, corrosive esophagitis is a serious problem that threatens life. These accidents increase by accessing generic cleaning supplies easily and taking preventive medicine measures inadequately. The aim of this study was to determine the demographic characteristics of people who had corrosive esophagitis and ensure the public awareness about these accidents.

Material&METHOD: We reviewed patients' files who hospitalized about corrosive esofagitis between January 2002 and December 2013, in Ondokuz Mayıs University, Department of Thoracic Surgery. 33 of 264 patients were excluded from the study because of taking corrosive for suicide.

RESULTS: 120 of the patients were women and 111 were men. Their age varied between 17 and 88 and the mean age was 40.2 years. 3% of them had a history of mental retardation and 33.6% of them smoked. The highest amount of accidents occurred in summer (38.5%). The ingested materials were bleaches (38.5%), nitric acid (21.6%), muriatic acid (8.2%). Only 3.9% of these products were branded. Patients were subjected wrong practices such as feeding with yogurt (14.8%) and drinking water(4.4%). Patients were hospitalized for 1 to 33 days. Also, average of 9.9 days in this period, they had prohibited oral intake.

Conclusions: It can be concluded that the subject of 'securing the living space' which is included in primary preventive medicine is one the main practice of family physicians. The role of the family physicians is very crucial since they are the first step of the health system.

The optimization of the nurse competencies in the management of acute disease in Primary Health Care

Gemma Puig Ponsico, Esther Díaz Salcedo, Cristina Gallardo Sánchez, Mònica Torremorell Núñez, Yolanda Espinosa Nieto, Maria Carmen Serrano Lozano, Asunción Juste Marin, Maria Rosario Mateo Gambarte, Carmen Úbeda García, Jaime Hernández Fernández, Alicia Blanco Díaz
Institut català de la Salut

Background and AIM

Primary health care (PHC) teams are the gateway in our health care system(HCS). Therefore, it is reasonable thinking about new organizational strategies to improve the efficiency of HCS and optimize the potential of each professional without implying a decrease in the quality of patient care. The nurse has a portofolio of own services among which care for people in acute pathology is contemplated.

The main objective is to analyze the results after designing a protocol where the nurse can provide coverage to the demand for acute pathology in a autonomous way.

Method

A retrospective cross-sectional descriptive study of the years 2013-2014 included all visits/year resolved by the nurse of patients who consult for acute pathology in our center. The motives for consultation that were included in the protocol were: anxiety attacks, emergency contraception, burns, diarrhea, acute low back pain, epistaxis, wounds, skin lesion zone fold, urinary discomfort, sore throat, toothache, elevated blood pressure, respiratory symptoms, ankle sprains, red eye, ear pain, flu, neck pain, contusions, fever, dizziness and bites.

Results

The population assigned to our heath area was 19,777 users, the average total visits/year in the period 2013-2014 were 119,846 (79,494 made by medical professionals and 40,352 nursing) Nursing solved 2,378 visits/year corresponding acute pathology consultations (5.89% of total visits made by nurses). The motives for consultations most visited were: wounds (34.29%), urinary tract symptoms (16.57%), respiratory symptoms (8.54%), neck pain (5.98%), acute diarrhea (5, 33%), burns (4.3%), back pain (3.7%), elevated blood pressure (3.59%).

Conclusion

The nurse has the necessary competencies to visit acute pathology.

Pathologies that nurses resolved more are wounds, urinary discomfort, respiratory symptoms, sore throat, diarrhea, burns, back pain and elevation of blood pressure.

The fact of having a protocol designed, helps keep the quality standards in this care process.

Chronical cough: The most unthinkable diagnosis

Gaston Ezequiel Vazquez, [Gemma Rovira Marcelino](#), Beatriz Jimenez Muñoz, Jordi Joseph Vilaplana, Helena Ferrer May, Rodrigo Perla San Martin, Clara Madueño Garro
EAP Sardenya, Barcelona, Spain

A 50 year-old female with gastroesophageal reflux history, presented to our health center referring non-productive cough started three weeks ago with no other symptomatology. The examination was normal, and omeprazole and loratadin was started as symptomatic treatment. Three month later, she is still with cough adding episodic acute left chest pain so chest X-ray was demanded for chronic caught study as per local guide. The examination revealed a homogenous mediastinal density in the left cardiophrenic angle. Continuing the study of mediastinal density a thoracic CT was performed finding a pericardial effusion located in the left cardiophrenic angle of 72 x 40 mm corresponding to a possible pericardial cyst. Pericardial cysts are usually asymptomatic. Symptoms are usually due to compression of adjacent organs and include atypical chest pain, dyspnea, and persistent cough. Pericardial cyst have an incidence rate of 1/100.000, they are rare mediastinal abnormalities. Most are congenital. The size varies from 2 to 28cm and the most common locations are middle mediastinum and right cardiophrenic angle (3/4), but in our case the location is unique, in the left cardiophrenic angle. Routine X-ray generally makes diagnosis incidentally. The confirmation is made by contrast Computed Tomography (CT) or echocardiography imaging.

CLINICAL TRIAL:

Pericardial cysts (72 x 40 mm)

DIFERENTIAL DIAGNOSIS:

Common causes: Gastroesophageal reflux, rhinitis, sinusitis, post-infection, tuberculosis, Iatrogenic/Drugs

Uncommon causes: Lung cancer, congestive heart failure, chronic aspiration, B. pertussis, pulmonary embolism, pleural effusion or other pleural or mediastinal tumors.

FINAL COMMENT:

Chest X-ray is needed to make differential diagnosis of atypical chronic cough and chest pain because incidental findings like mediastinal abnormalities could be a rare but possible finding. We describe an unusual presentation, which was diagnosed during the evaluation of non-productive chronic cough. GP should be persistent in common pathology study to rule out rare but treatable causes of them.

Keywords: Chronical cough, pericardial cyst, mediastinal abnormality

Prolonged "tonsillitis" in a young woman

Diogo Alves, [Gui Santos](#)

Unidade de Saúde Familiar Villa Longa

Background and AIM: In primary healthcare the family Physician must frequently manage illness which presents in an undifferentiated phase and has the additional responsibility of making efficient use of health-care resources. This case aims to illustrate these competences of the family physician who must often coordinate care work with other professionals and take an advocacy role for the patient.

METHODS-RESULTS: 27 year old female, belonging to a Duval phase 3 nuclear family, allergic to penicillin, who, in an urgent consultation, complains of pain in the right hemiface, exacerbating with mastication, and presenting oedema and pain in the right cervical region. A dental abscess is diagnosed and medicated with cefuroxime. 18 days later, due to progressive worsening, with fever, tonsillar purulent exudate, odynophagia and painful right-side cervical adenomegalia, she is referenced to the local hospital, for observation by otorhinolaryngology. In the emergency room the patient was not observed by otorhinolaryngology, but discharged with instructions

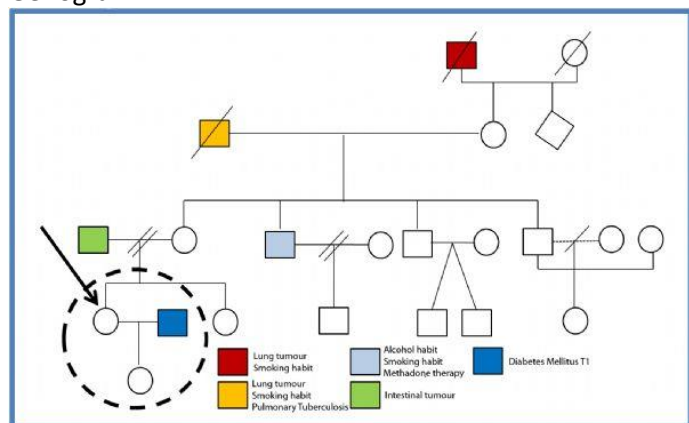

touse a mouthwash. 38 days after the initial symptoms, the patient presents right side cervicalgia, poliartralgia, weight loss, fever and a 3cm tumefaction in the right cervical region.

The clinical condition did not improve and led, 61 days after the initial symptoms, to the diagnosis of Hodgkin Lymphoma confirmed by ganglion biopsy.

CONCLUSIONS: This case emphasizes the importance of a better articulation between family physicians and hospital doctors regarding the patients' best interest.

Angiotensin-converting enzyme inhibitor-induced angioedema: an undiagnosed case report

Erica Mendes

UCSP de Tarouca, ACES Douro Sul, Tarouca, Portugal

BACKGROUND & AIM: Angiotensin-converting enzyme inhibitors (ACEi) are one of the most effective, well tolerated and prescribed antihypertensive drugs worldwide. Like other medications, there are some adverse effects and angiotensin-converting enzyme inhibitor-induced angioedema (ACEiIA) is one of them, with a reported incidence ranging from 0,1 to 2,2%. The ACEiIA normally resolves without treatment within hours or days but it can potentially be fatal and is commonly underdiagnosed. This report aims to describe an undiagnosed case of ACEiIA.

METHOD: To make this report we used the clinical process complemented with a bibliographical research.

RESULTS: A hypertensive 71 year old man patient was medicated in December 2013 with an ACEi (lisinopril). In 2014 he presented 3 episodes of unilateral upper lip swelling that were resolved. In January 2015 he presented to the emergency service with an 8 hours history of tongue swelling. There was no rash, pruritus or another symptom. He was treated with oral corticosteroid and his symptoms improved within 24 hours. After, he was observed by his family physician (FP) who reviewed his history and prescription. He was diagnosed an ACEiIA, confirmed after lisinopril suspension and resolution of the angioedema.

CONCLUSION: The ACEiIA diagnosis is clinical and is frequently undiagnosed, especially in patients with mild clinical presentation. This case highlights the importance of clinical history and evaluation of these patients in order to make an early and appropriated diagnosis. It is essential to immediately discontinue any ACEi therapy and provide supportive care. The efficacy of epinephrine, antihistamines, or corticosteroids remains controversial. Antagonists of bradykinin or concentrates of C1 inhibitor are being studied to use in the ACEiIA treatment. The FP plays a crucial role in the diagnosis and treatment of ACEiIA, and sometimes only the integration of information by the FP allows a correct diagnosis of undiagnosed cases.

Case Report: Choroidal Melanoma Presented as Unilateral Angle Closure Glaucoma

Milica Brkic, Kristina Markovic, Marko Stankovic, Veroslava Maksimovic, Ana Krivokapic
Department of General Medicine, Health Center "Dr Simo Milosevic", Belgrade, Serbia

INTRODUCTION: Choroidal melanoma is the most common eye malignancy, but still a rare condition (2-8 cases per 1000000 people in Europe). Most patients are asymptomatic, others may experience flashing light, floaters or loss in visual field. There are few reported cases of choroidal melanoma presented as angle closure glaucoma.

CASE: 80 years old man consulted GP for pain and redness of his left eye, pupil dilatation and visual loss that he developed during last 3 days. He had no previous medical history, but family history of cutaneous melanoma. The affected eye showed fixed mydriasis, conjunctival chemosis and no light perception. Intraocular pressure was 40 mmHg in the left and 14 mmHg in the right eye. He was referred to ophthalmologist who prescribed medical therapy. The pain continued despite medication and after initial decrease of intraocular pressure as low as 28 mmHg, it rapidly increased up to 55 mmHg. Eye ultrasonography revealed choroidal melanoma complicated with retinal ablation and intraocular hemorrhage. Due to complete visual loss and uncontrolled intraocular pressure causing severe pain, enucleation was performed. Histopathology confirmed choroidal melanoma with transscleral penetration and vorticosae vein infiltration. After 3 months follow-up, no metastases occurred.

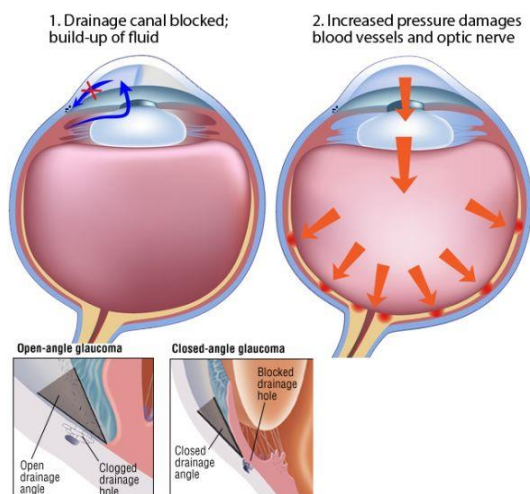

CONCLUSION: Every case of angle closure glaucoma should be evaluated carefully with insisting on imaging methods in order to rule out secondary causes, especially because early diagnosis and smaller intraocular melanomas are associated with better prognosis. Family history of melanoma should always draw our attention.

Abdominal pain and longstanding constipation without improvement

Antonio Ubiña Carbonero¹, Julian Zarco Manjavacas², Carmen Maria Lopez Rios¹, Francisco Jose Cervilla Suarez²

¹CS Victoria

²CS El Palo

Personal History: No known drug allergies. In tamsulosin for BPH. No other relevant history. Smoking 4-5 cigarettes / day.

Anamnesis: 61 year old male who came to casualty with abdominal discomfort and constipation 9 days duration with 2 isolated episodes of rare and hard defecations. No vomiting or fever during the process. Previously consulted with diagnosis of urinary tract infection and was prescribed him antibiotics amoxicillin-clavulanate without improvement. Denies expulsion of gases in recent days. Hyporexia associated with abdominal discomfort.

Physical examination: Abdomen: globular, soft and palpable, no masses or organ enlargement. Bowel sounds present. Murphy negative. Positive Blumberg. Pain on deep palpation and irritation voluntary defense in hypogastric region and right iliac fossa. Digital rectal: sphincter competent, no palpable masses, dedil goes stained dregs remains, no other medical products. Rest of examination: no significant findings.

Complementary tests: Blood test: leukocytes 15900 (N 80.5%, L 9.8%), C-reactive protein 172. Abdomen X-ray: without significant disturbance. Abdominal US: wall thickening of bowel loops in pelvis. Abdominal CT with contrast: complicated appendicitis with plastron and collections.

Diagnosis: appendicitis vs intestinal obstruction.

Evolution: according to the findings, is contacted Surgery for case valuation by deciding to conservative management.

CONCLUSION: the occurrence of appendicitis in patients of advanced age between symptoms may include bowel obstruction, so that in these cases the physical examination is a useful tool to guide the diagnosis.

Abdominal pain in patient with hyperglycemia

Antonio Ubiña Carbonero¹, Julian Zarco Manjavacas², Carmen Maria Lopez Rios¹, Francisco Jose Cervilla Suarez², Gloria Amaranta Martinez Alonso²

¹CS Victoria

²CS El Palo

Personal History: No known drug allergies. Unremarkable history. Family history of diabetes (mother and father insulin therapy, siblings oral antidiabetic treatment).

Anamnesis: Man of 35 years admitted with symptoms of pain in the left abdomen of 5 days duration that appears after ingestion and is accompanied by dry mouth, polydipsia, polyuria, weight loss (8 kg in a week), heartburn, nausea and vomiting of food content that does not relieve pain. Pain unirradiated. No fever. No changes in bowel habits. No voiding syndrome. Similar episode a month earlier, which partially resolved with use of omeprazole

Physical examination: Abdomen soft and palpable, no masses or organ enlargement, tenderness to palpation in epigastric region, left upper quadrant and flank, without defense or peritonitis, Blumberg and Murphy negative. Rest of exploration without findings.

Complementary tests: Blood test: glucose 358 mg/dl, pH 7.22, HCO₃ 11.2 mmol/L, EB -14.9 mmol/L. Urinalysis: glucosuria (4+), ketonuria (3+). Chest X-ray: no significant findings. Abdomen X-ray: no significant findings.

Diagnosis: diabetic ketoacidosis in debut

Evolution: fluid therapy is initiated and insulin infusion with rapid-acting insulin to control blood glucose levels and normalize the pH. After several hours with this treatment, the analytical tests show improvement in the numbers of blood gases (pH 7.33) with good diuresis and good overall condition. After that, patient admission charge of Endocrinology for diabetes education.

CONCLUSION: abdominal pain associated with the cardinal symptoms may be one of the symptoms of diabetic ketoacidosis appearance in both diabetic debut and decompensation in a poorly controlled diabetes.

Dyspnea in women with reduced mobility

Antonio Ubiña Carbonero¹, Julian Zarco Manjavacas², Carmen Maria Lopez Rios¹, Francisco Jose Cervilla Suarez²

¹CS Victoria

²CS El Palo

Personal History: No known drug allergies. Schizophrenia. Current treatment: clomipramine, topiramate, Adiro, trimipramine, alprazolam, propranolol.

Anamnesis: 78 year old woman who comes to the emergency department brought by ambulance by feeling fatigue of recent onset. The family refers pallor and decay. In the last 48 hours she has submitted hip pain for which has taken anti-inflammatory. Concerns in recent days dyspnea with ambulation with a walker. Discuss cold symptoms in previous days without expectoration, well tolerated. 112 ambulance objectives hypotension (70/38) and 94% O2 Sat at initiating perfusion with saline and transferred to Hospital.

Physical examination: mucocutaneous pallor. Cardiac auscultation: rhythmic and regular tones, no murmurs.

Respiratory auscultation: vesicular murmur preserved without stridor or wheezing. Rest of examination: anodyne.

Complementary tests: Blood test: leukocytes 19610 (N 94.4%, L 3.1%), D dimer 19261.9, urea 109, creatinine 2.97, LDH 342, lactate 3.7, C-reactive protein 206. Gas analysis: pH 7.252, PCO2 43, PO2 22.9, HCO3 18.6, EB -7.3.

Angio-CT: no signs of PTSD are objectified.

Diagnosis: respiratory origin likely sepsis

Evolution: the patient is admitted to the observation area to start treatment with fluid therapy, antibiotics; blood and urine cultures being filed.

CONCLUSION: the differential diagnosis of dyspnea in an immobilized patient should include screening for PTSD.

Keywords: dyspnea, hypotension, reduced mobility

Angio-CT

Gait disturbance in polymedicated patient

Antonio Ubiña Carbonero¹, Carmen Maria Lopez Rios¹, Julian Zarco Manjavacas², Francisco Jose Cervilla Suarez², Maria Vilchez Jaimez¹

¹CS Victoria

²CS El Palo

Personal History: No known drug allergies. Ex smoker for 40 years. Dependent for basic activities of daily living. Hypertension, Chronic obstructive pulmonary disease, permanent atrial fibrillation, acute myocardial infarction in 2007, senile dementia, prostate cancer 15 years ago. Current treatment: pantoprazole, Adiro, triflusal, torasemide, amiodarone, spironolactone, isosorbide mononitrate, Atrovent, Ventolin, Spiriva, lorazepam, Tardyferon.

Anamnesis: 85 year old male who came to emergency department with gait disorders and swallowing liquids difficulties. 8 days prior consultation regarding benzodiazepine poisoning episode. Since then, her daughter refers that he did not complete improvement of the medical picture with persistent unstable gait and exacerbation of symptoms of dementia with worsening at night. It is derived from the Primary Care Centre to screen for new cerebrovascular event.

Physical examination: Neurological examination: no alteration of cranial nerves. No alterations in the strength or sensitivity, unstable gait with small shuffling steps. Osteo-tendon reflexes present. Rest of exploration: anodyne.

Diagnosis: stroke vs pharmacological intoxication.

Complementary tests: Blood test: no significant findings. Urinalysis: nitrites +, leukocytes +++. Benzodiazepines positive. Cranial CT: marked enlargement of the lateral ventricular system and of the third ventricle, which could be related to normal pressure hydrocephalus; hypoattenuation of the periventricular white matter; marked sulcus along convexity in relation to cortical atrophy.

Evolution: the patient was discharged with follow-up by Neurology consultation in the Memory Unit for organization of further tests and follow-up by Neurosurgery consultation.

Conclusion: the appearance of symptoms of dementia in elderly patients with polypharmacy forces us to look for possible causes such as infection or intoxication, in addition to rule out a cerebrovascular event.

Progressive edema of lower limbs and choloria in patients with Diabetes Mellitus

Antonio Ubiña Carbonero¹, Nerea Canton Cuadrado³, Julian Zarco Manjavacas², Carmen Maria Lopez Rios¹, Francisco Jose Cervilla Suarez²

¹CS Victoria, Malaga, Spain

²CS El Palo, Malaga, Spain

³CS Trinidad, Malaga, Spain

Personal History: No known drug allergies. Dyslipidemia, type-II diabetes. Current treatment: omeprazole.

Anamnesis: 48 year old woman was admitted to observation area to present lower limb edema following thighs until 2-3 months duration. Previously she had never submitted. Treated by her GP with diclofenac, but since then refers darker and turbid urine.

Physical examination: dryness of mucous membranes. Respiratory auscultation: bibasilar crackles. Abdomen: globular, wall edema, pain on deep palpation, positive left renal percussion. Pitting edema to root thighs. Rest of examination: anodyne.

Complementary tests: Blood test: leukocytes 15400 (N 14500), glu 567, C-reactive protein 109. Abdominal US: bilateral pleural effusion in abundant amount, left kidney with poor corticomedullary differentiation and air in the urinary tract. Abdominal CT: emphysematous cystitis, urethritis left emphysematous, left kidney emphysematous pyelonephritis (type II Wan), generalized edema of the subcutaneous cellular tissue, bilateral pleural effusion in abundant amounts. Portable echocardiography: no pathological findings.

Diagnosis: cystitis / urethritis / emphysematous pyelonephritis in poorly controlled diabetic patient with nephrotic syndrome associated probable.

Evolution: Urology valued by deciding nephrostomy catheter placement by Vascular Radiology, leaving frank hematuria. Subsequently, log in charge of Urology for IV antibiotic treatment, but during admission have worsening overall for decompensated heart failure recent diagnosis that requires transfer to ICU for hemodynamic stabilization.

CONCLUSION: urinary tract infections are very common in diabetic patients with poor control, so that before the appearance of signs of infection in these patients, physical examination and imaging tests realization is essential for the correct diagnosis of these pathologies with high rates mortality.

The risks of urban sports

Julián Zarco Manjavacas¹, Carmen María López Ríos², Antonio Ubiña Carbonero², Juan Pablo García Paine³, Enrique Alarcón Pariente¹, Francisco José Cervilla Suárez¹

¹C.S. El Palo, Málaga, Spain

²C.S. Victoria, Málaga, Spain

³Department of Emergency, H. Parque San Antonio, Málaga, Spain

Personal History: male, 24 years.

Present Illness: patient come after crash while he was practicing skateboarding.

Physical Examination: Good overall condition. Pale. Pain in lower limbs and difficulty to move them. Pain to palpation in pubic region.

Complementary tests: no alterations in blood test. Pelvic CT: inferior left ramus pelvic fracture. Sacral wings bilateral compression fracture.

Diagnosis: sacrum and pelvis fracture.

Evolution: in control blood test, the patient present hemoglobine in 9.1 (previously 13.5) asymptomatic. Admitted in Traumatology plnat.

CONCLUSION: sports and lifestyle have consequences in health of our patients and produce atypical injuries unrelated with the age of the patient.

Keywords: lifestyle, pelvis fracture, anemia

TRANSFUSIONS and PRIMARY CARE

Juan Jesus Rodriguez Vallejo¹, Hector Leonardo Lugo Ramos², Pedro Guijo Gonzalez¹, Jose Maria Fernandez Gonzalez¹

¹Hospital Jerez de La Frontera

²CS Delicias

OBJECTIVES

At present, the role of the family doctor in blood transfusions is poorly documented

In order to reflect this action, we have prepared this work with the following OBJECTIVES:

Describing blood transfusions performed in an emergency department.

Evaluate the adequacy of referrals from primary care for transfusion in patients at risk.

MATERIALS AND METHODS

Retrospective study in the emergency department of a secondary hospital with a time of ninety-day study, data were collected through the database of the blood bank and by "Diraya" program to analyze the clinical profile of patients. Variables analyzed were age, sex, hemoglobin, cause of transfusion, destination and referrals from primary care. Data were analyzed using SPSS v.21.

RESULTS

A total of 148 patients were transfused and analyzed, most men(61.49%) and women(38.51%). The average age was 71±16 years, provenance: by own means 55.41%, 29.05% primary care, UVI 10.14%, 5.41% other. The causes of transfusion: chronic anemia(66.22%), gastrointestinal bleeding(31.76%) and uterine bleeding(2.03%).

Cardiovascular risk factors were identified: Hypertension arterial 52%, 39.9% diabetes, dyslipidemia 25%, ischemic heart disease 11.5% 8.1% stroke. Pre-transfusional media Hb was 6.6g / dl ± 1.36 and Post-transfusional Hb 8.2g / dl±1.38. Patients referred from primary care Pre-transfusional Hb 6,06g/dl±1.07R3.8 to 7.9 patients admitted for other means Pre-transfusional Hb6,85g / dl±1.4R3,9 to 13.2. Of referred from primary care, causes: 83% chronic anemia, 11.6% gastrointestinal bleeding and 4.7% uterine bleeding, and who entered through other means: 59% chronic anemic, 40% gastrointestinal bleeding and 1% uterine bleeding. Subsequent destinations were: 54.05% admission to hospital plant, 44.59% discharge home and 1.35% exitus.

CONCLUSIONS

One third of transfusions performed in a hospital emergency department were indicated by referral from primary care. The main cause of transfusion was chronic anemia, being also the most common in patients referred from primary care. The ciphers for pre-transfusion of patients referred from primary care hemoglobin were lower than those of patients admitted from other origins.

Keywords: blood transfusion primary care hemoglobin

PROVENANCE

- Own means

Sudden headache in young patient

Antonio Ubiña Carbonero¹, Julian Zarco Manjavacas², Carmen Maria Lopez Rios¹, Francisco Jose Cervilla Suarez²

¹CS Victoria, Malaga, Spain

²CS El Palo, Malaga, Spain

Personal History: No known drug allergies. No clinical history.

Anamnesis: 25 year-old female was admitted to the Observation area for sudden headache in the afternoon. She reports that while she was watching TV at home, she has begun with abdominal pain that radiated to the back and then to the neck and head. No previous effort related. Her relatives comment disconnection of the medium episode. Cannabis in the last month in relation to stress by parental separation.

Physical examination: disorientation and somnolence with good response to painful stimuli. Unreactive mydriatic pupils. Bilateral extension plantar reflex. No alteration of cranial nerves. No alterations in the strength or sensitivity. Rest of examination: anodyne.

Complementary tests: Cranial CT: intraventricular bleeding in frontal and temporal horn of the left lateral ventricle, frontal horn of the right lateral ventricle and III and IV ventricles, with no signs of herniation and hydrocephalus at scan. Urinalysis: cannabis positive.

Diagnosis: hemorrhagic stroke.

Evolution: after valuation by Nuerosurgery and Neurology, she was decided to transfer to ICU for monitoring and follow-up assessment by Vascular Radiology, who performed arteriography where vascular nidus was found in the left posterior choroidal artery, with an aneurysm within the vascular tangle, possible cause of the bleeding.

CONCLUSION: Any sudden headache with unusual appearance and characteristics should be studied to rule out the presence of subarachnoid or intracranial hemorrhage.

Excessive exercise can not be healthy

Julián Zarco Manjavacas¹, Carmen María López Ríos², Antonio Ubiña Carbonero², Juan Pablo García Paine³, Gloria Amaranta Martínez Alonso¹, Francisco José Cervilla Suárez¹

¹C.S. El Palo, Málaga, Spain

²C.S. Victoria, Málaga, Spain

³H. Parque San Antonio, Málaga, Spain

Personal History: male, 21 years. Without interest.

Present Illness: the patient consults for pain in upper limbs and coluric urine after intense exercise three days ago.

Physical Examination: Good overall condition. Impossibility to make complete extension in upper limbs.

Complementary tests: blood test with CK 67.275 without affectation of kidney function.

Diagnosis: rabdiomilisis.

Evolution: the patient stays in Observation Area for 24 hours. When it is objectified that he does not suffer kidney affectation is discharged.

CONCLUSION: excessive exercise ca have consequences against health patients which have to be prevented.

Keywords: rabdiomilisis, sport, young patient

P-0279

Unstable gait and paraparesis in lower limbs in young patient

Antonio Ubiña Carbonero¹, Carmen Maria Lopez Rios¹, Julian Zarco Manjavacas², Francisco Jose Cervilla Suarez², Nerea Canton Cuadrado³

¹CS Victoria, Malaga, Spain

²CS El Palo, Malaga, Spain

³CS Trinidad, Malaga, Spain

Personal History: No known drug allergies. No previous pathology of interest. No standard treatment.

Anamnesis: 24 year old male who presented at our Emergency episode of weakness in lower limbs with unstable gait 2 days duration. Difficulty recently added to move the toes. Left frontal dominance headache associated. No fever or vomiting. No visual or level of consciousness or difficulty in speech disorders. Episode 10 days before tympanic perforation that required antibiotics.

Physical examination: Glasgow 15/15, isochoric and reactive pupils, no nuchal rigidity, no alterations in cranial nerves. No limb differences. Decreased strength in both lower limbs with paresthesias. Upper limbs preserved and symmetrical sensitivity and strength. Abolished patellar reflex and Achilles reflex. Positive Romberg.

Unsteady gait with increased base of support. No alterations in language. Symmetrical palpable carotid pulse.

Rest of examination: anodyne.

Complementary tests: Blood test: no significant findings. Chest X-ray: no significant findings. Cranial CT: no significant findings.

Diagnosis: peripheral neuropathy ascending to rule Guillain-Barré syndrome

Evolution: Neurology is contacted for evaluation meanwhile, decides admission to the ward to complete the study with EMG and ENG and early empiric treatment with gamma globulin. During admission diagnosis of Guillain-Barré syndrome is confirmed.

CONCLUSION: the establishment of a Guillain-Barré syndrome can be difficult to diagnose, so the history is very important (history of infections). It should be noted if symptoms are symmetrical, speed of onset of symptoms, the disappearance of reflexes.

Keywords: unstable gait, lower limb paresis, Guillain-Barré syndrome

Abdominal pain and fever like alarm symptoms

Julián Zarco Manjavacas¹, Carmen María López Ríos², Antonio Ubiña Carbonero², Juan Pablo García Paine³, Juan Paz Galiana⁴, Luis Antonio Calleja Cartón¹

¹C.S. El Palo, Málaga, Spain

²C.S. Victoria, Málaga, Spain

³Department of Emergency, H. Parque San Antonio, Málaga, Spain

⁴Department of Emergency, H. General de Tomellos, Tomelloso, Ciudad Real, Spain

Personal history: male, 67 years. No drugs allergies. Hypothyroidism.

Present illness: the patient consults for fever for 10 days. The patient has received treatment with Levofloxacin suspecting respiratory infection. Fever persists after finishing the treatment. In the current moment, he presents abdominal pain in the right lower quadrant and asthenia and anorexia.

Physical examination: Not fever. Good overall condition. Profuse sweating. No breathing noises. Pain to palpation in right lower quadrant where there appears to be a mass.

Complementary tests: abdominal CT: mass in right colon complicated with inflammatory plaques of the adjacent fat with little abscesses and liver injuries that seem like an abscess and another injury that looks like a metastasis.

Evolution: the patient is admitted by General Surgery to study the mass and start a new treatment.

CONCLUSION: many times the patient comes to us with a diagnosis that we have to confirm or refuse, but if the treatment does not work correctly, we have to investigate it, because it can be a mistake.

Keywords: Fever, abdominal pain, colon cancer

P-0281**Consciousness crisis**

Slavica Vrtarić, Darko Vrtarić

Department of Public health, University of Josip Juraj Strossmayer, Osijek, Croatia

A 23-year-old male student was admitted urgently to the Neurology Clinic for experiencing a 1-minute grand mal epileptic seizure. According to the heteroanamnesic data, the young man was asleep when he suddenly jerked and fell off the bed, all of his limbs were convulsing, he also bit his tongue and foamed out of his mouth, with no loss of control of bowel or bladder functions. After the seizure he felt confused for a while. This was the first time he had ever experienced a seizure.

Over the past two weeks he has been stressed out and under intense pressure having slept only 3 to 4 hours per day, spending his days studying all the time and in front of the computer. According to his girlfriend, every day for the last two weeks he would have recurring episodes of becoming absent-minded, staring blankly during the conversation and becoming briefly unaware. He denied consuming alcohol, drugs or any medications and did not have a fever.

On physical examination, the patient is alert, conscious, responsive, oriented, is able to move the neck, normally innervated cranial nerves, able to maintain all four extremities symmetrically against gravity, with symmetrical myotatic reflexes, normal bilateral plantar response, all sensations are normal, able to normally perform the coordination tests, the Romberg test is negative, normal ability to walk, the tongue bite is visible, no external head injuries, blood pressure 145/95.

Diagnostics: MSCT of the brain, MR of the brain, Color Doppler of carotid arteries, EEG and ECG, all of which indicate normal results, biochemical results are within normal values.

CONCLUSION: Risk behaviour, which is in this case associated with a lack of sleep and spending too much time in front of the computer, can lead to severe consequences even in healthy people, such as an epileptic seizure described in this case.

Keywords: epileptic seizure, lack of sleep, computer

P-0282**Musculoskeletal persistent pain with no logic cause should be exhaustively studied**

Cristina Vidal Ribas, Pedro Vidal Vaz, María Albaladejo Blanco, Ignacio Ramírez Manent, Eduardo Hernández Deleón

primary care center, Mallorca, Spain.

COMPLAINT:

36 year old female, consults for several week evolution right shoulder pain that worsens when lifting her arm and with nocturnal predominance. She associates it with exercise.

CLINICAL HISTORY:

- Smoker 1 pack/day
- No other interesting records

PHYSICAL EXPLORATION:

Right shoulder: no deformities, generalized pain in proximal third part of the humerus that worsens with mobilization.

DIFFERENTIAL DIAGNOSES:

Musculoskeletal pain.

COMPLEMENTARY TESTS:

- X-Ray: given as normal.

EVOLUTION AND FINAL DIAGNOSE:

2 months later the patient comes back to consult for persistence of the symptoms with aggravated dysfunction of the shoulder, besides she presents hip pain and loss 7Kg in this last 2 months. We ask for blood testing and reassess the x-ray where a loss of density is seen, we decide to repeat the x-ray.

- Blood: no abnormalities
- X-Ray: Lithiasic process in right greater tubercle.

When the patient comes for the results we performed new physical complete exploration finding a mass in left breast and axillar lymphadenopathies. The patient is admitted to the hospital where breast cancer diagnose is confirmed and extension studies reveal pulmonary, hepatic bone, peritoneal, renal and suprarenal

DISCUSSION:

Breast cancer is the most frequent cause of bone metastasis. In some occasions bone pain can be its first symptom, therefore, although the pain is diagnosed as musculoskeletal, if it doesn't show any improvement with analgesics, the patient should be submitted to further testing and complete physical exploration.

In this case the patient was only 36 with no familiar history, so she wasn't included in the breast cancer screening program. However we should consider that about 95% of Breast Cancer cases have no genetic disposition.

Fever and back pain in a patient with Psoriatic Arthritis

Gui Santos¹, Ricardo Antunes², Cláudia Penedo³

¹USF Villa Longa

²USF Quinta da Lomba

³USF Emergir

BACKGROUND-AIM: Family Medicine, usually the point of first contact with Healthcare Services, manages undifferentiated pathology that may require urgent intervention. With this case we aim to show the need to differentiate usual chronic complaints from new pathology that may present with unspecific symptoms.

Methods/RESULTS: 61 year-old male, unemployed, married, in a Duvall phase VI nuclear family, a history of Hypertension, Psoriatic Arthritis (PA) and Generalised Anxiety Disorder, with no significant family history; medicated with naproxene, prednisolone, metotrexate, omeprazole, lisinopril+hydrochlorothiazide and diazepam.

A frequent user of Healthcare Services, often complaining of articular pain related to PA associated with anxiety. In August the patient complains of fever and joint pain, common in him, being medicated with anti-pyretic and anti-inflammatory, and blood-work is requested.

The patient returns in September due to maintenance of fever and dorsal discomfort. Previous white-cell count is normal, negative C-reactive protein, and Sedimentation Rate of 60, to be expected in psoriatic arthritis. He is medicated with tramadol. He returns very anxious with fever and generalised pain, and goes to his Rheumatologist who confirms PA crisis and escalates medication.

In October symptoms remain, now accompanied with lower limb paresthesia, muscle strength asymmetry and Laségue sign. Exacerbation of PA is assumed.

Three months after initial complaints, due to exacerbation of dorsalgia, the patient is referred to the Emergency Room. A Computerized Tomography reveals epidural abscess with medular compression, treated with decompressive laminectomy of D5-D7 and abscess drainage which revealed Acid Alcohol-Resistant Bacilli.

CONCLUSIONS: This is a patient whose PA masked the presentation of Vertebral Tuberculoma. Given his frequent use of services due to pain, complicated by anxiety, it became difficult to differentiate acute from chronic symptoms. We demonstrate the need of high clinical suspicion in patients with chronic conditions, given the risk of neglecting acute pathology that may go unnoticed.

Keywords: Family Medicine, Psoriatic Arthritis, Acute disease, Chronic disease, Tuberculosis

P-0284

Not always a cough and thoracic pain is a cold

Cristina Vidal Ribas, Padro Vidal Vaz, María Albaladejo Blanco, Ignacio Ramírez Manent, Eduardo Hernández Deleón, Adriana Helmfelt Minobis
primary care center, Mallorca, Spain.

COMPLAINT: 58 year old male consults for 1 week cough and throbbing right thoracic pain that worsens with cough and deep inspiration. It is diagnosed as pharyngitis and muscular pain. After less than a week patient returns complaining of dyspnea and low fever. He has had Ibuprofen (no improvement).

CLINICAL HISTORY:

- Former smoker, 20 packs/year.
- Arterial Hypertension.
- Mix dyslipidemia.
- Diabetes mellitus type II.

- Normocytic normochromic anemia. Diagnosed months before because of weakness. In blood test Hb: 11.5mg/dL, with negative test for blood on stools. We agreed new Hb determination in 3 month that was not performed.

Usual treatment: amlodipine 5mg; Lisinopril 20mg; metformin 850mg; simvastatin-ezetimib.

PHISICAL EXPLORATION (2nd consulting):

- TA 171/91, FC 89, SatO2 98%
- Normal cardiologic examination.
- Respiratory auscultation with bilateral basal.

DIFFERENTIAL DIAGNOSIS:

- Respiratory tract infection
- Pulmonary embolism

Because of bad evolution we send him to the emergency department.

COMPLEMENTARY TESTS:

- ECG: SR, 98bpm, repolarization syndrome.
- Thoracic X-Ray: normal.
- Blood: Dimer D 261, urea 78, creatinine 3,23 (before 1,29), non-ionized calcium 11.4, chlorine 113.

EVOLUTION AND FINAL DIAGNOSE:

Unknown Kidney Insufficiency (secondary to Ibuprofen)

Hyperkalemia and hiperchloremia.

Facing a possible pulmonary embolism heparin treatment was initiated and the patient was assigned to the nephrology unit for kidney function deterioration and persistent hyperkalemia. An hematological neoplasia was suspected and after observation of a "salt and pepper" (photo 1) pattern in cranial bone series and both kidney and bone marrow biopsy confirmation, Multiple myeloma was confirmed.

DISCUSSION:

A normocytic anemia can be the first manifestation of systemic disease. Unspecific signs and symptoms should be studied and additional tests performed. Blood determinations as reticulocytes count, iron profile and leucocytes and platelets anomalies have special meaning when dealing with cases like these. Patients with non-affiliated normocytic anemia neither associated to chronic disease should be sent to hematology unit for further testing.

Keywords: Common cold Chest pain Multiple Myeloma

Thoracic X-Ray

Thoracic X-Ray: normal.

salt and pepper pattern in cranial bone series

P-0285

Muscle pain, no dyspnea... Can it be a pneumothorax?

Cristina Vidal Ribas, Pedro Vidal Vaz, María Albaladejo Blanco, Ignacio Ramírez Manent, Laura Medrano
primary care center, Mallorca, Spain.

Complaint: Chest pain

Personal history: 10 cigarettes per day; no interesting medical records.

Anamnesis/interrogation: 18 years old male, consults the doctor for 5 hour mild chest pain, especially with deep breathing. Describes it as sharp, non-radiating, increasing with efforts. No dyspnea. He explains that he is doing exercises with weights and, in the past, he had felt the same feeling; on those occasions the doctor said it was due to muscle strain.

Physical examination: TA 135/80, FC 80, SatO2 96-97%. Hypo phonetic right thorax.

Investigations:

- Arterial blood gas analysis: pO2 78, PCO2 35, pH 7.47
- ECG: anodyne
- Chest X-ray: lung collapse

Diagnostic impression: pneumothorax.

Differential diagnosis: mechanical pain (prior to physical examination and investigations).

Treatment: In the emergency room, a drainage needle is inserted, oxygen, and advise resting. In our consult, we advise to stop smoking.

Evolution:

Until now, he has not presented a similar episode.

CONCLUSIONS:

When we see a young a tall patient with smoking habit and with dyspnea we should always think of pneumothorax. In spite of this, sometimes the patient doesn't complain about dyspnea, they consult only for chest pain. For this reason vital signs monitoring, physical examination and some simple complementary tests, like ECG or X-ray are quite important diagnosing tasks.

In this kind of pathology, the recurrences are very common. Therefore we have to work on risk factors such as smoking, diving or excessive exercise

Approach of Male Breast Symptoms in Primary Care: an Algorithm

Ana Sofia Pena¹, Ana Matos², Ana Paula Cardoso¹, Mariana Anete Mira¹, Susana Cordeiro Rita¹

¹USF Samora Correia, ACES Estuário do Tejo, ARSLVT, Portugal

²UCSP Benavente, ACES Estuário do Tejo, ARSLVT, Portugal

BACKGROUND-AIM:

Although less frequent, breast symptoms and pathology occur in men too, so they should be considered and assessed in male.

Motivated by clinical cases, we thought useful to perform a literature review upon this topic to establish an approach algorithm of these situations for Primary Care.

METHODS:

We performed a literature review searching the MeSH terms “breast symptoms”, “breast pathology”, “primary care” “man” and “male” in the databases Pubmed, Medline, ScienceDirect, Medscape e UptoDate.

RESULTS:

We selected articles written in english between 2000 and 2014. We excluded several that not comprised the male population.

The majority of breast male pathology is benign. Gynecomastia is the most frequent problem. Breast male cancer is rare (<1% of breast cancers) but deserves our concern, as its incidence is rising and early diagnosis happens seldom. Other breast male pathologies are related to skin and subcutaneous tissue.

The main reasons that lead men to seek medical advice are: rise in breast volume, breast lump and breast pain.

The approach of these patients should include: anamnesis comprising age, race, family history, personal history of disease or trauma, exercise habits, medication, alcohol and drug use and symptoms characterization; examination, including feminization signs, signs of liver, thyroid or kidney disease, evaluation of lymph nodes, testicles and breast.

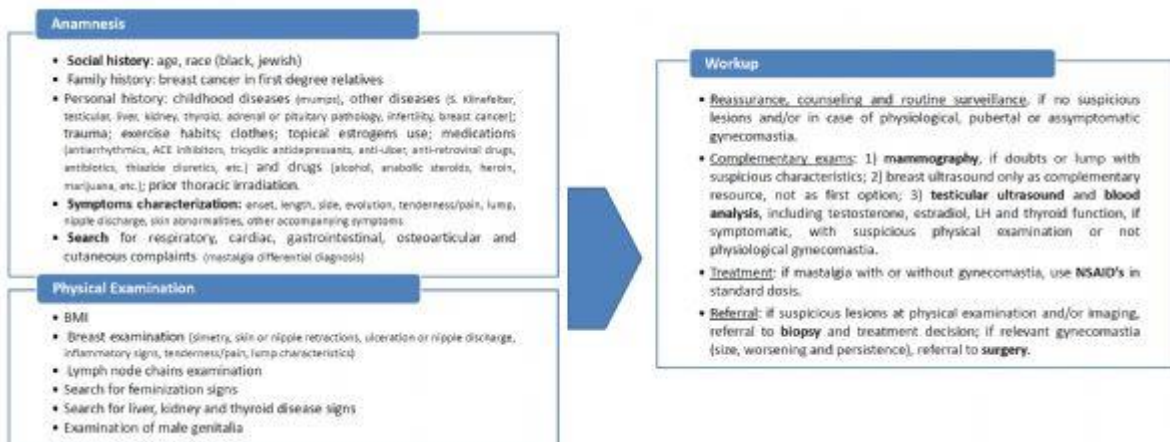

This assessment will guide the complementary exams to request (lab and/or imaging tests). The referral for biopsy and therapeutic guidance is necessary in some cases. In others the tranquilization of patient and education for surveillance and re-evaluation will be enough.

CONCLUSION:

Though uncommon, breast male pathology exists and we should be aware to perform a systematic approach in order to detect on time and characterize correctly the condition. A structured anamnesis and a complete observation will guide the need for complementary tests and enable early diagnosis and action plan decision.

Keywords: breast male symptoms, breast lump, breast pain, gynecomastia, breast male cancer

Approach of Male Breast Symptoms

P-0287

{Heart aches} – the importance of taking a step back and looking in perspective

Isabel Santos Solha, Lisete Aires Silva

Usf Terras de Souza, Aces Tamega II - Vale de Sousa Sul, Paredes, Portugal

Setting: Family Medicine is known for its patient centered approach, guided by family and community contexts. Family Doctors have the ability to juggle multiple complaints, in view of health promotion, disease prevention, treatment, palliative care and rehabilitation. Cough and dyspnea are very common symptoms that require a systematic and thorough evaluation of the patient in order to determine the most probable cause of illness. Case description: J.A.B.J., male, 49 years old, construction worker, married, nuclear family, stage 5 of Duvall, Class II of Graffar. His history also includes smoking (35 pk-yr), alcohol consumption (70 g/day) and illicit drug use. This man comes for a consultation cough and dyspnea on light exertion. Physical examination was normal and he was treated symptomatically. On a second consultation, the complaints persisted and there weren't any alterations on the requested chest x-ray. Few days later, he was medicated with several antibiotics and bronchodilators in a ER consultation, with no improvement of his symptoms. In another consultation, with another doctor, he presented with persistent cough for two months, mucous sputum, dyspnea on moderate exertion, orthopnea and chest pain. ECG and echocardiogram suggested dilated cardiomyopathy, with severe ventricular dysfunction (EF=22%). He was then medicated with furosemid (60mg id) and carvedilol (6,25mg id), requested a workup including Pulmonary Function Tests, and sent to an urgent cardiology consultation. Patient improved his symptoms from a NYHA class III to class II.

Discussion: Ischemia is the main cause for dilated cardiomyopathy (50%); substance abuse (mainly alcohol and cocaine) account for nearly 3% of the causes. This case reminds us the importance of a global approach of patient history. Searching for signs and symptoms from another point of view allows us to determine the correct diagnosis and proper orientation to other specialists, with a positive impact on patient's quality of life.

P-0288

Baker cyst. A rare case

Juan Manuel García López, Verónica Parent Mathias

Department of Emergencies, Regional Hospital, Málaga, Spain

OBJECTIVE: to present an unusual case of Baker's cyst.

METHOD: case.

It is a 24 year old male with no known pathology that goes to ER for pain in the right calf region of more than 1 week duration. He reports that he has received tumor in the area has increased over time (months). No recalls previous trauma. On examination, tumor ranging from upper third to the middle third of twin without observing involvement of posterior aspect of the knee is appreciated. No functional impairment or hematoma and palpation perceived stony consistency with mild displacement of the structure. X-leg where injury is seen in upper third tibia compatible with chondroma is performed. It requesting consultation with trauma ultrasound tumor area proving to be compatible with Baker cyst tension. The orthopedic surgeon proceeds to needle aspiration thereof, introduced betamethasone and outpatient appointment for review.

CONCLUSION: This is an unusual case because Baker cyst is related to patients middle-aged, with arthritis or osteoarthritis or meniscal history of involvement, facts that do not occur in this case.

Syncope. What to look for in the electrocardiogram

Juan Manuel García López, Verónica Parent Mathias

Department of Emergencies, Regional Hospital, Málaga, Spain

OBJECTIVE: To identify electrocardiographic tracings that can justify the cause of syncope.

METHOD: literature review.

For a patient who comes in for syncope, we must make a electrocardiograma, but what we find in the plot to justify syncope?

Paths that can explain what happened are:

- Persistent sinus bradycardia (<40 bpm).
- Sino-atrial block or equal to or greater than 3 sec sinus pauses.
- Complete atrioventricular block or second degree Mobitz type I or II.
- Right bundle branch block and left bundle alternating.
- Sustained or uncontained ventricular tachycardia.
- Rapid supraventricular tachycardia.
- Long or short QT syndrome.
- Brugada pattern type I.
- Bifascicular bundle branch lock (LBBB or right bundle branch block with left anterior hemiblock or left posterior hemiblock).
- Intraventricular conduction disorders with QRS> 120 ms.
- Wolf-Parkinson-White.
- Paths suggestive of ischemic heart disease.
- Q waves suggestive of myocardial necrosis.

If we see any of these patterns, we must refer the patient to the ER for evaluation by a cardiologist.

Keywords: syncope, arrhythmias.

Fahr disease is a rare finding in a primary care consultation, has a low prevalence and unknown etiology and only a complementary test could offer a correct diagnosis. We present a 68 years-old woman, consulted her family doctor about some speech difficulties she had been having for around 3 months. She commented some other difficulties that follow that problem like impossibility of doing the basic homework or having the sensation of moving around from left to right and some short-term memory problems. No headache, no loss of strength or sensory alteration, but her husband referred some clumsiness that had not been there before. Medication: metformin, treatment for Diabetes Mellitus type 2. No other illness. Physical exploration was normal, neurological assessment without alterations and ECG in sinus rhythm. A CT-SCAN was demanded in a quick circuit, in a week the results said that exits bilateral calcification of basal ganglia and cerebellums surface, with clinic exploration could be a Fahr disease. A citation with Neurology has been made and some analysis with Ca 2 ++ levels. Nowadays, the patient has been attending the follow-ups, analysis were normal without significative alterations and the difficulties continues. Treatment was not supported, but in literature is said that lithium or antidepressives could be used. In front of a patient with memory and coordination problems it is necessary exclude infection disease, endocrine alteration or neoplastic tumours and complementary test are a must in primary care.

Time-dependent variations in physicians' information needs during working hours

Jukkapekka Jousimaa, Heidi Alenius, Nora Berghem, Ilkka Kunnamo

Duodecim Medical Publications Ltd, Helsinki, Finland

Background & Aim

The patients' reasons to visit a doctor's practice can be expected to vary considerably depending on the appointment time. This could also influence the physicians' information needs during the working hours. To verify this hypothesis, we checked hour - by - hour 50 most popular searches done to EBMG, an electronic point-of care database for primary care physicians, during a 12-month period. The main question was, if there were time-dependent differences in searched topics.

Method

From a log file, we collected retrospectively a Top-50 list of all searched topics hourly. The collection period was 4.3.2014 – 3.3.2015. The searched topics were divided in 24 hour-by-hour groups, starting from 24.00 and ending 23.59 and analyzed by their relative reading frequency during each time period.

Results

During the data collection period, altogether 14 million searches were done to the database. The quietest hour was between 4-5 a.m. (Top-50 contained 4362 searches) and the busiest time interval was between 10-11 a.m. (Top-50 contained 241779 searches). The nature of searched topics varied greatly diurnally. During normal office hours (8-16) searches containing chronic disease conditions like asthma and diabetes were prominent, while during duty hours, acute conditions like laryngitis and pneumonia were the most common in relation to each other. Some common examples are shown in Figure (to be added in presentation).

Conclusions

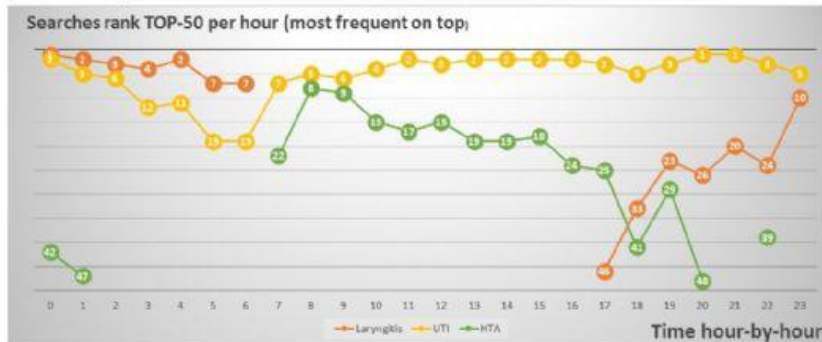

Automatically collected log files provide evidence from patients' visiting reasons and physicians' information needs depending on the timing of the visit. This information can be used in optimizing electronic database performance as well as planning how to provide resources optimally.

Indomethacin-induced Psychiatric Disorder

João Fernando Martins Machado, [Mariana Fidalgo Ferreira Leite](#)
Unidade de Saúde Familiar Saúde no Futuro. Vila Nova de Gaia. Portugal
INTRODUCTION/BACKGROUND

Non-steroidal anti-inflammatory drugs are commonly used in general practice; indomethacin is one of the most potent drugs of this class. Psychiatric adverse events, even though not frequent, have been described with indomethacin, particularly in elderly and patients with previous psychiatric disorders.

CASE REPORT

The authors present the case of a 44 year-old female with medical history of dysthymia, previous ovarian cancer and urinary incontinence, currently treated with paroxetine 20 mg, alprazolam 1,5 mg and temazepam 20 mg daily.

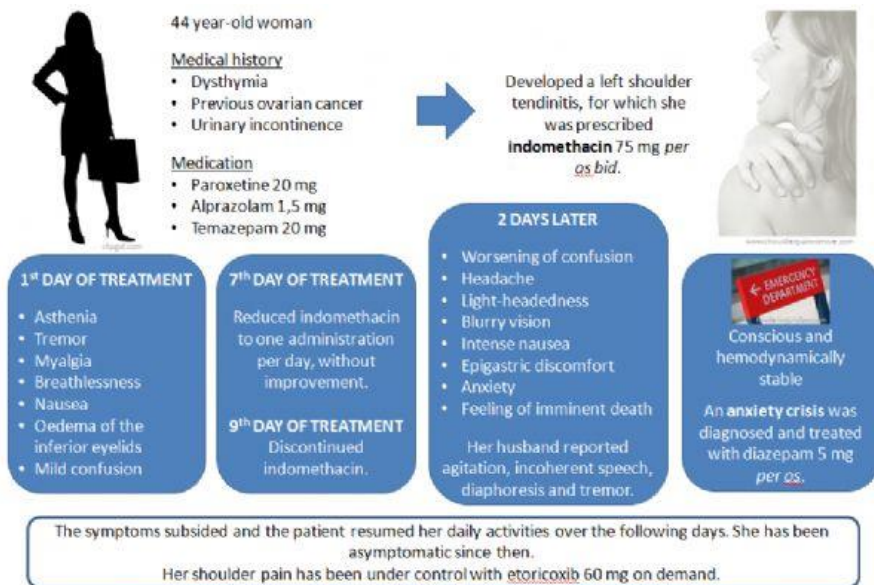

Shortly after being medicated by her family doctor with indomethacin 75 mg per os bid, to treat a left shoulder tendinitis, the patient developed asthenia, tremor, myalgia, breathlessness, nausea, oedema of the inferior eyelids and mild confusion. On the seventh day of treatment, she reduced indomethacin to one administration (75 mg) per day, without improvement; she discontinued indomethacin two days later.

The next day, she experienced worsening of confusion, accompanied by headache, light-headedness, blurry vision, intense nausea, epigastric discomfort, anxiety and a feeling of imminent death. Her husband reported agitation, incoherent speech, diaphoresis and tremor. She was taken to the local emergency department, where she arrived conscious and hemodynamically stable; she was treated for an anxiety crisis with diazepam 5 mg per os. The symptoms subsided and the patient reassumed her daily activities over the following days. She has been asymptomatic since then. Her shoulder pain has been under control with etoricoxib 60 mg on demand.

DISCUSSION/CONCLUSION

The mechanism through which indomethacin induces psychiatric adverse events is not yet well understood; however it may reside on the similar molecular structure between indomethacin and serotonin. Family doctors should be aware of the possibility of these adverse events, particularly in elderly and in patients suffering from psychiatric disorders, whom may be at higher risk.

Are antibiotics, for patients presenting with sore-throat symptoms in primary care, correctly prescribed?

Kuresh Khodatars, Soleman Begg

St George's University of London, London, United Kingdom

Background and AIM:

Antibiotic use has become increasingly important and controversial. Their necessity and benefit for health is widely known. However current antibiotics are becoming ineffective. Their high usage is linked to an increase in antibiotic resistant bacterial populations. The rate of resistance development is higher than antibiotic replacement production. This issue's seriousness is recognised by WHO as a major public health threat. One solution is to slow rates of resistance through reducing the number of antibiotics in circulation, by implementing efficient prescribing guidelines. Pharyngitis has been subjected to such regulations. The majority of afflicted patients do not need antibiotics. However, over cautiousness caused over-prescribing in previous years. This audit aims to evaluate whether antibiotics, for patients with sore-throat symptoms, are correctly prescribed after modified guidelines were introduced.

METHOD: All relevant consultations, from a GP surgery serving 4000 people, were recorded and scrutinised against NICE guidelines. Selection was based on all GP consultations where, within the past three months, patients presented with sore-throat symptoms and were prescribed a relevant antibiotic.

RESULTS: 31 prescriptions, of which 14 were for delayed prescriptions, were in accordance with NICE guidelines. One prescription was not in accordance; it should have been for delayed, rather than immediate, dispensing.

CONCLUSIONS: During the winter season, the GP surgery had done well to prescribe pharyngitis related antibiotics in accordance with NICE guidelines. The adoption of delayed prescriptions, with the overall benefit of reducing antibiotic use, has been successful. However the single exception emphasises the need to reinforce, to both patients and clinicians, the importance and benefit of using delayed prescriptions through clear and concise explanations. Patients should receive this from clinicians and easily accessible awareness information. This may help tackle patient expectations of immediate antibiotics, whilst reducing unnecessary delayed prescription redemptions. The authors have no competing interests to declare.

Coluria as acute epigastric pain and symptoms of acute Hepatitis B

Carmen María López Ríos¹, Antonio Ubiña Carbonero¹, Julián Zarco Manjavacas², Juan Pablo García Paine³, Juan Paz Galiana⁴, Luis Antonio Calleja Cartón²

¹C.S. Victoria, Málaga, Spain

²C.S. El Palo, Málaga, Spain

³Department of Emergency, H. Parque San Antonio, Málaga, Spain

⁴Department of Emergency, H. General de Tomellos, Tomelloso, Ciudad Real, Spain

Personal History:

Female 37 years. Allergy to Penicillin. No surgical medical history of interest.

Present Illness:

She came to the emergency Epigastralgia seven days of evolution accompanied by malaise and fatigue, nausea without vomiting, no diarrhea or fever. Also referred darker than usual urine.

Physical Examination:

Cardio-pulmonary auscultation average. Abdomen nondescript except hepatomegaly two traverses. No edema in legs. I request blood tests for virus serology.

Complementary tests:

Analytical count and normal coagulation. Biochemistry with Total Bilirubin 4.84, 3.89 Direct, GOT 1386, GPT 1149, VHA 148. FA negative, positive Agc HBV, HBV positive Ags

Diagnosis: Acute hepatitis HBV

Evolution: It quoted the patient and contact history on risk. She is single, born in Russia, lived in Spain since 2012. She is administrative. Sexual activity, oral sex a month ago with a stranger and she tattooed eyebrows two months ago. Share floor with an old woman.

Protocol: Declare Notifiable disease, we conducted epidemiological survey of hepatitis B and asked about close contacts prophylaxis if needed. Lower labor and Digestive derivation. We use to guide bedrest with residue diet. Repeat analytic in two months to assess treatment. Notified from M. Preventive places to study contacts and health inspection of address where the tattoo was done.

Acute Viral Hepatitis A in Young Male Adults at southeast region in Turkey

Mehmet Aytug Dikililer¹, Umit Aydogan², Oktay Sari², Salim Ozenc³, Bayram Koc²

¹Family Medicine Clinic, Ankara Military Hospital Anittepe Polyclinic, Ankara, Turkey

²Department of Family Medicine, Gulhane Military Medical Academy, Ankara, Turkey

³Family Medicine Clinic, Diyarbakir Military Hospital

Introduction and AIM: Acute viral hepatitis (AVH), is the most common liver disease and continues to be a major health problem in public health all throughout the world. In this study, we aimed to investigate the duration of hospital stay and examining the laboratory findings because of hepatitis A virus infection (HAVI) which cause for the significant loss of labor in our country. The Files of Patients that were treated for diagnosis of HAVI in January 2010 – December 2011 were examined in internal medicine clinic of Sırnak Military Hospital.

RESULTS: Sixtysix male patient included the study. Mean age was $22,05 \pm 2,81$. Mean hospitalization time was $10,55 \pm 5$. According to the patient complaints there were % 63,6 nausea/vomitting, % 43,9 weakness, % 10,6 fever, % 42,4 darkening of urine, % 57,6 jaundice, % 40,9 anorexia, % 6,1 diarrhea, % 7,6 headache. In physical examination there were % 84,8 jaundice, % 12,1 hepatomegaly, % 13,6 splenomegaly, % 9,1 right upper quadrant tenderness, % 3 roughing in breath noises. Biochemical parameters were wbc: $6,61 \pm 2,08$ hgb: $15,44 \pm 2,28$, plt: $220,98 \pm 81,05$ alt: $1080,65 \pm 1532,48$ ast: $869,67 \pm 1598,73$, alp: $165 \pm 112,07$, havIgM: $8,33 \pm 6,94$ Tblb: $6,63 \pm 3,91$, d.blb: $3,14 \pm 2,59$. The complications were % 3 bicytopenia, % 10,5 trombocytopenia, % 1,5 elevated liver enzymes, % 3 cholecystitis.

CONCLUSIONS: HAVI is an important community health problem in regions that have infrastructure problems and low hygienic conditions. HAVI which was expected to occur in older ages in our country, may present with more severe disease and its complications and it must be evaluated carefully by the family physicians.

Limitations on approach of secondary hypertension in Primary Health Care

Teresa Pereira Martins, Bruno Vaz, Helena Ribeiro, Samuel Pedreira
 USF Novos Rumos - ACES Alto Ave, Portugal

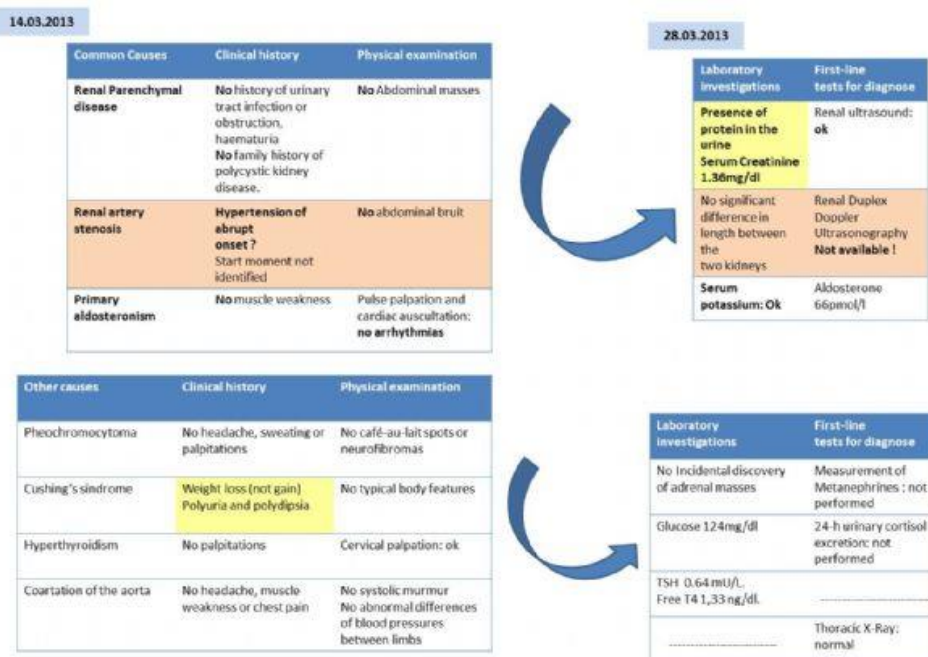

BACKGROUND: Secondary hypertension is about 5 % to 10 % of all cases of hypertension. The existence of a secondary cause should be considered in all hypertensive patients, and patient approach, through clinical history, physical examination and study diagnose, can confirm their presence. It is up to family physician, as a first line in health care, the detection and proper orientation of these situations.

Case description: Male of 38-years-old, healthy, complains of polydipsia, polyuria and a recent weight loss (about 3kg in 2 weeks), with no reasonable cause. During the meeting, he reports high values of blood pressure (some of 190/90mmHg), confirmed in the physical examination. There were no physical signs indicate possible causes for secondary hypertension. The initial study included laboratory investigations, electrocardiogram, chest radiography and renal ultrasound. Once in a referral center, the study indicated renal arteries stenosis.

DISCUSSION: Hypertension guidelines of 2013, from European Society of Hypertension, recommend the screening and study of possible reversible causes of hypertension on all patients. Almost all kind of initials studies may be performed in Primary Health Care in Portugal, with the only exception of renal duplex doppler ultrasonography. When stenosis of renal arteries is suspected or no other cause of secondary hypertension is determined, the patient should be referred to a specialized center for further studies. Will we have more benefits if that kind of study were available in Primary Care? And if we cannot totally conduct a study of identifiable causes of hypertension, should we start the study at all, or simply refer the patient?

Keywords: secondary hypertension, primary health care

Varicella Encephalitis In Patient Coming With Afebrile Convulsions: Case Report

Nadiye Karabulut¹, Özlem Sazak¹, Seçil Günher Arıca¹, Bahar Çalışkan², Murat Eleveli²

¹Haseki Eğitim ve Araştırma Hastanesi, Aile Hekimliği Kliniği, İstanbul

²Haseki Eğitim ve Araştırma Hastanesi Pediatri Kliniği, İstanbul

Introduction:

Chickenpox (varicella), often a self-limiting disease, is characterized by a vesiculobullous rash and its infectious agent is varicella zoster virus. Neurological complications of the varicella infection often occur within 2 to 6 days after the rash onset. Meningoencephalitis is the second most common Neurological complication of varicella, and its mortality rate varies between 5-20%. The clinical course goes with the changes in the level of consciousness, convulsions, fever, headache, and neck stiffness. In this case report we will describe a case of meningoencephalitis seen after varicella infection

CASE: 12-year-old girl was brought to the emergency department with afebrile convulsions and minor head trauma. Glasgow Coma Skale score was 8 but vital signs, cerebrospinal fluid (CSF), hemogram, blood electrolyte levels, kidney and liver function tests were within normal limits. Brain CT scan was also normal. A few crusted varicella vesicles were observed on her back associated with varicella infection she had 5 days ago and the results of the Brain MRI with contrast was consistent with meningoencephalitis.. The minor head trauma in her anamnesis was also tricky. When we questioned her parents deeply, it was clear that she lost her consciousness prior to falling down and crushing her head. Varicella encephalitis was diagnosed and acyclovir, levetiracetam treatment was started. She fully recovered without sequelae.

RESULT: In our case, the lab, CSF results and the Brain CT scan was normal. There were no specific findings in the CSF and blood lab result for diagnosis. As shown in this case; anamnesis, physical examination are more important than advanced laboratory examinations for the diagnosis and treatment of diseases.

Acute intoxication for metformine

Julián Zarco Manjavacas¹, Antonio Ubiña Carbonero², Carmen María López Ríos², Juan Pablo García Paine³, Juan Paz Galiana⁴, Luis Antonio Calleja Cartón¹

¹C.S. El Palo, Málaga, Spain

²C.S. Victoria, Málaga, Spain

³Department of Emergency, H. Parque San Antonio, Málaga, Spain

⁴Department of Emergency, H. General de Tomellos, Tomelloso, Ciudad Real, Spain

Personal history: female, 71 years. No drugs allergies. Diabetes mellitus type 2. in treatment with metformine. Bipolar disorder.

Present illness: patient presented to the emergency after ingesting 50 metformine tablets (42,5 gr.) with autolytic notion. Good diuresis. Normal blood pressure. Good oxygen saturation.

Blood test: lactic acidosis with increasing blood creatinine (from 0.6 to 1.4 mg/dl).

Diagnosis: kidney failure after acute drug intoxication with autolytic notion.

Evolution: the patient is admitted in ICU to make hemofiltration having a good response to treatment, presenting afert it a normal kidney function.

CONCLUSION: any medication can be used with autolytic notion. Although is not very common in attempted suicide, metfformine can have serious consencuencias in big doses.

Keywords: Metformine, acute intoxication, autolytic.

A strange X-ray with an unusual sign

João Rocha Moutinho, Diana Almeida Ferreira

Unidade de Cuidados de Saúde Personalizados da Mealhada

INTRODUCTION: The Chilaiditi's sign is a rare radiological sign, asymptomatic, which is characterized by the presence of temporary or permanent hepatodiaphragmatic interposition of the bowel, involving specially the transverse colon and that can be seen on a chest X-ray. It's incidence in radiographs is between 0.025% and 0.28% including all age groups, increasing slightly in over 60 years of age and is more common in men than in women, in a ratio of 4:1. Chilaiditi's sign can be attributed to various anatomical variations, including absence of the suspensory ligaments of the transverse colon and falciform ligament of the liver, redundant colon, right diaphragmatic paralysis and enlargement of the thorax leaving extra space for potential colon migration.

Case description: ♂, 67 years old, caucasian, belonging to a nuclear family, in Phase VIII of Duvall Cycle, lives with his wife. Currently has hypertension, dyslipidemia and obstructive sleep apnea, treated with enalapril 5mg, atorvastatin 40mg and nasal continuous positive airway pressure (CPAP). Consulted emergency rescue because of headaches, chest pains, permanent cough. dyspnea and fever and a diagnosis of community-acquired pneumonia was made. After the complete empirical antibiotic treatment, consulted the family doctor to a clinical, laboratory and radiological reevaluation, where he presented a chest X-ray with Chillaiditi's sign.

DISCUSSION: The Chilaiditi's signal is a rare entity, usually found incidentally on imaging tests. Usually is a benign and asymptomatic signal but requires a differential diagnosis of the right subphrenic airspace included pneumoperitoneum, diaphragmatic hernia and subdiaphragmatic abscess. Despite being benign it requires medical vigilance because when symptoms are involved it is called Chillaiditi's syndrome and can be accompanied by abdominal pain, nausea, retrosternal pain, respiratory symptoms vomiting, bloating, intestinal obstruction or subocclusion and in this case an extensive medical evaluation is vital and in some situations surgery is required.

Keywords: Chilaiditi, pneumonia, X-ray

Chest X-ray with the Chilaiditi's sign.

Presence of a bowel loop in the hepato-diaphragmatic space.

Electrocardiogram and chest pain in real practice - A retrospective cohort study in Family Practice in Portugal

Paulo Santos¹, Carlos Martins¹, Paulo Pessanha², Manuel Viana², Luísa Sá¹, Alberto Pinto Hespanhol¹, Altamiro Costa Pereira³, Luciana Couto¹

¹General & Family Medicine Unit - Department of Social Sciences and Health, Faculty of Medicine of University of Oporto, Portugal

²Family Health Unit of S. Joao of Porto, Porto, Portugal

³Information Sciences and Decision on Health Department (CIDES), Faculty of Medicine, Centre for Research in Health Technologies and Information Systems (CINTESIS), University of Porto, Porto, Portugal

BACKGROUND: Electrocardiogram (ECG) plays a major role in the study of chest pain.

AIM: To measure the impact of making an ECG in patients with chest pain (CP) in Primary Care.

METHODS: We conducted a retrospective cohort study of patients with CP that made an ECG in a Primary Care setting by comparison with those who made the ECG as a routine test, in order to measure the change of cardiovascular clinical guidance up to 6 months after ECG. Cases were categorized in atypical or typical CP. Secondary a clinical practice analysis was performed, counting the number of medical visits 12 months before and after ECG.

RESULTS: We studied 480 patients, consecutively selected during 4 years, 333 in CP group (286 with atypical CP), and 147 controls. Patients with typical CP presented higher changing in clinical guidance (RR=4.299; 95%CI:2.378–7.772, p<0.001) than patients with atypical CP (RR=1.116; 95%CI: 1.008–1.235, p=0.047), when compared with controls. In the routine group there wasn't any variation of visits counting, as in the typical CP group, but a reduction of 0.59 visits (95%CI: -0.90 to -0.29;p<0.001) occurred in the atypical CP patients one year after the ECG. Anxiety was significantly associated to atypical CP orientation.

CONCLUSIONS: Making an ECG leads to a higher referral to hospital care, but doesn't affect the therapeutics or the request of other tests in CP patients, with a decrease in office visits among those with atypical pain, reflecting a significant impact on its health status, thus justifying its use.

ECG and chest pain in real practice

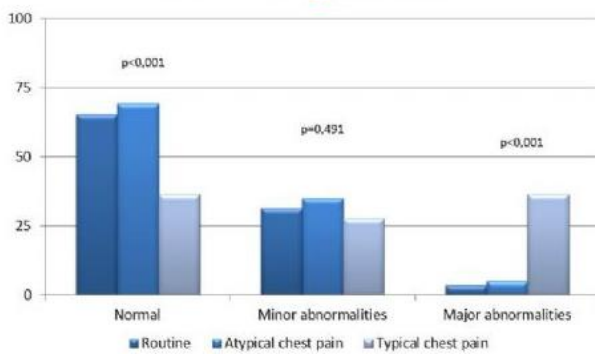

Comorbidities

Comorbidities

ECG diagnosis

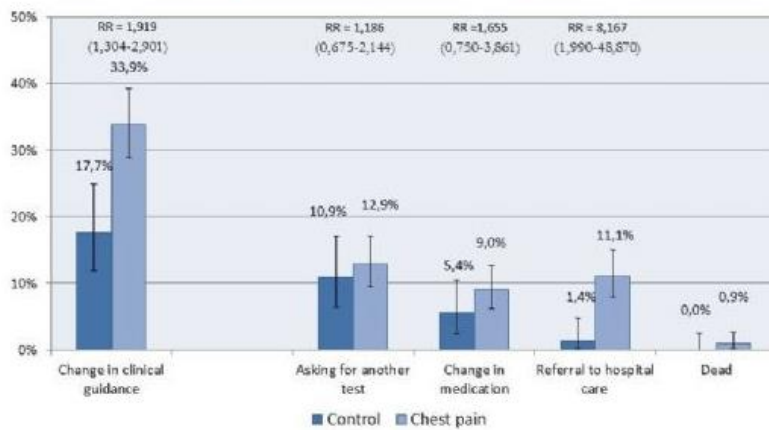

ECG diagnosis

Results of ECG in included patients

Change in clinical guidance

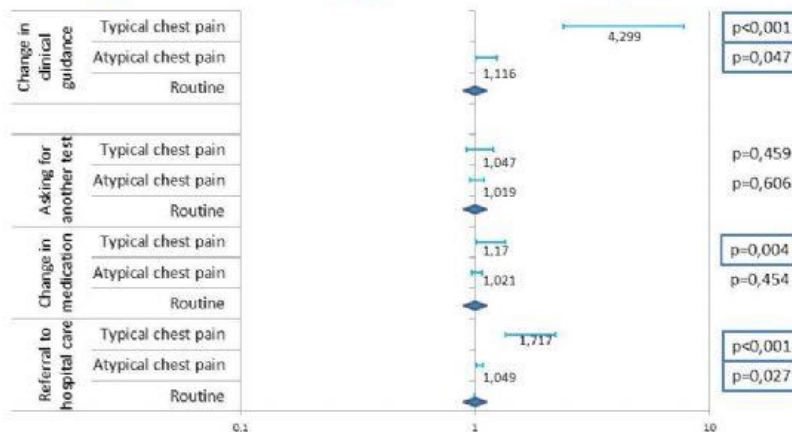

Change in clinical guidance

In patients with chest pain, the change in clinical guidance depends mainly of the reference for hospital care. There's no change in medication or asking for another test in both groups.

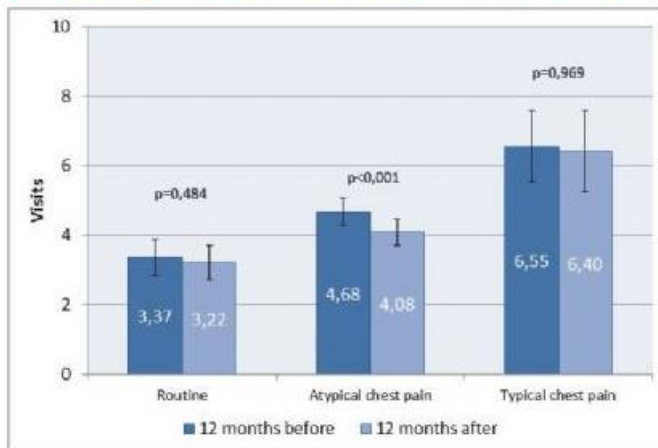

Typical vs atypical chest pain

Typical vs atypical chest pain

The direct comparison of patients with typical and atypical chest pain. The key factor for decision making is the presence of anxiety together with an abnormal ECG. This brings to the discussion the need for reassurance that a normal test can strengthen.

Clinical practice activity analysis

Patients of routine group didn't show differences in the counting of visits before and after making the ECG. The same occurred in the patients with typical chest pain, which maintained the pattern of access to their doctors. On the other hand, patients with atypical chest pain had a reduction of 0,6 visits 12 months after the test. This is consistent with the hypothesis of the ECG have a positive therapeutic effect on reassurance of patients, reflected in the improvement of the demand of health care

P-0304

Pemphigus Vulgaris vs Bullous Pemphigoid

Teresa Pereira Leite¹, David Rodrigues², Marta Lopes², Nidia Nunes², Susana Grilo Lourenço²

¹USF Alcoides, ARS Alentejo, Montemor-O-Novo, Portugal

²USF Planície, ARS Alentejo, Évora, Portugal

Pemphigus are autoimmune bullous dermatosis that affect 0,5 to 3 per 100.000 individuals. They are characterized by the presence of autoantibodies against desmosomes of keratinocytes leading to acantholysis and formation of intraepidermal bubble. These are severe diseases with a mortality rate of 5 to 15%. Pemphigus vulgaris is the most common form, accounting for about 80-85% of cases. Pemphigoid are also autoimmune bullous dermatosis, whose resemblance to the pemphigus justifies its designation. In those cases bubble formation results from cleavage of the dermal-epidermal junction, affecting the hemidesmosomes. Prognosis is favorable in most situations. Bullous pemphigoid is the most common form, being the most prevalent bullous dermatosis, with an estimated incidence of 7 million cases per year in Western Europe. Despite the similarity between the clinical presentation of pemphigus vulgaris and bullous pemphigoid, these conditions have distinct prognosis and severity, so it is crucially important to differentiate them. The aim of this work is to briefly describe these dermatosis, highlighting the main features that distinguish one from another.

Literature search was undertaken in February 2015 in Dermatology textbooks and Medline database of review articles published between 2010 and 2015 in portuguese and english, using the MeSH terms "pemphigus vulgaris" and "bullous pemphigoid".

Of the 263 articles that met the inclusion criteria, 5 were relevant to the realization of this work. The main differences observed between pemphigus vulgaris and bullous pemphigoid reside in: epidemiological aspects (incidence, prevalence, age and gender of affected individuals); clinical manifestations (symptoms, usual location and characteristics of the lesions); physical examination findings; etiology; histopathology; immunopathology; disease progression and prognosis. The treatment of both dermatosis is based on corticotherapy.

The distinction between pemphigus vulgaris and bullous pemphigoid can be a diagnostic challenge. However, these conditions have specific characteristics, allowing a definitive diagnosis based on clinical aspects and histopathological examination.

Keywords: "Pemphigus Vulgaris" "Bullous Pemphigoid"

Table 1 - Main differences between Pemphigus Vulgaris and Bullous Pemphigoid

		PEMPHIGUS VULGARIS	BULLOUS PEMPHIGOID
Epidemiological Aspects	Incidence	1/1.000.000 person year	21/1.000.000 person year
	Age	between 40 and 60 years	> 50 years, mostly between 75 and 80 years
	Gender	no predominance	male predominance
Clinical Manifestations	Typical Signs/Symptoms	severe pain in erosion areas (mucosal and cutaneous), anorexia and sialorrhoea	prodromal pruriginous uncharacteristic dermatitis
	Lesions Usual Location	oral mucosa (first weeks), upper torso, head, neck, pressure zones and large cutaneous folds	large skin folds, inner surfaces of thighs, lower abdomen, often with symmetry
	Lesions Characteristics	sero-haemorrhagic flaccid blisters, millimetric and fragile that increase peripherally causing large erosion areas	tense blisters, some large and confluent, with sero-haemorrhagic content and erythematous base
Physical Examination Findings		positive Nikolsky sign	negative Nikolsky sign
Etiology		genetic factors combined with triggering factors (drugs, infections, vaccines, stress)	genetic factors combined with triggering factors (drugs, cancer, UV radiation)
Histopathology		intraepidermal suprabasal cleavage (acantholysis)	dermal-epidermal cleavage (basal lamina)
Immunopathology		antibodies "pemphigus type" against desmoglein 1 and 3 of the desmosomes of acanthocytes	antibodies against bullous pemphigoid 1 and 2 antigens of hemidesmosomes
Disease Progression		severe, chronic and persistent	usually self-limited
Disease Prognosis		bad prognosis, high mortality associated	favorable prognosis in most situations

P-0305

Paracetamol Effect on Blood Pressure: What is the Evidence?

Sara Quelha, Bruno Morrão
 USF Arca d'Água; ACeS Porto Oriental; Porto; Portugal

Background and AIM: Paracetamol is one of the most consumed drug in the world, and its use is due to its antipyretic and analgesic activity of mild to moderate pain. In view of the fact that the anti-inflammatory non-steroids are associated with increased blood pressure and interfere with antihypertensive drugs, paracetamol was taken as a safe and recommended as first-line analgesic in patients with cardiovascular morbidities. However, recent studies call into question their safety. The objective is to evaluate the safety and effect of paracetamol on the level of blood pressure.

METHODS: Systematic review through electronic search engines Cochrane, DARE, Bandolier, National Guideline Clearinghouse, Guidelines finder, Canadian Medical Association Practice Guidelines Infobase and Medline.

RESULTS: In the total of 154 articles were analyzed 4 articles (1 systematic review, 1 randomized trial and 2 cohort studies). The only systematic review included 19 holds articles in which two of them demonstrate a significant increase in systolic blood pressure between 3 to 4 mmHg (p <0.05) and the other items did not found any change. In the randomized clinical study there was an increase of 4.4 mmHg in systolic blood pressure and 2,9mmHg in diastolic blood pressure (p <0.05). The two analyzed cohort studies have shown a blood pressure increase in relation to the use of paracetamol reaching a level difference in systolic blood pressure of 1,6mmHg.

CONCLUSION: The effect of paracetamol in blood pressure and its safety in patients with cardiovascular risk factors is unclear. Blood pressure should be strictly monitored whenever the paracetamol use in these situations. In the future will require more homogeneous and consistent studies to tackle the weaknesses of the current evidence.

Keywords: paracetamol; acetaminophen; blood pressure

Corticosteroid injection for adhesive capsulitis in primary care: a review

Koh Kim Hwee

Tampines Polyclinic, Singhealth Polyclinics, Singapore

Background & AIM:

Adhesive capsulitis is a common condition causing shoulder pain and stiffness. Most patients can be managed with non-operative treatment in the primary care setting & corticosteroid injections are among the more commonly used intervention. However, there is currently a lack of good evidence to support its efficacy, especially in the long term, and its use compared to other modalities. The objective of this review is to assess the efficacy of corticosteroid injections for adhesive capsulitis.

METHOD:

PubMed and CENTRAL databases were searched from Dec 1994 to Dec 2014. Randomised controlled trials (RCTs) reporting the efficacy of corticosteroid injections in adhesive capsulitis versus placebo and other non-operative treatment modalities, as well as those that investigated different doses and different injection techniques were included. JADAD scoring system was used to assess the methodological quality of the included studies. The conclusions and results of the identified studies based on their outcome measures were then summarised.

RESULTS:

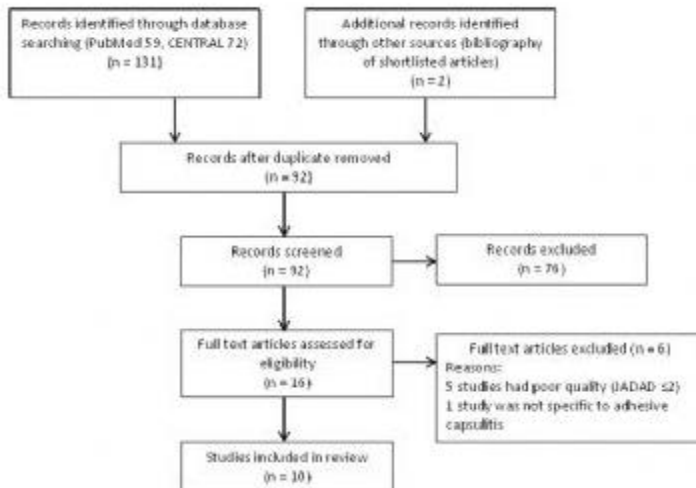

Fifteen RCTs were reviewed. Intra-articular corticosteroid was found to be superior to no treatment (1 trial) and normal saline (1 trial) up to 12 weeks. Corticosteroid injection led to more rapid improvement compared to physiotherapy and their combination was better than either modality alone. Use of 40mg triamcinolone acetonide was superior to 10mg but there were no difference between 20 and 40mg use. Subacromial injection had similar outcomes as glenohumeral injection. Intra-articular corticosteroid injections led to faster improvement compared to oral steroids but there were no difference when compared to oral NSAIDs. Ultrasound guidance also led to improved outcomes compared to blind injections.

CONCLUSIONS:

In the primary care, physicians should consider corticosteroid injection as the first line treatment and consider concurrent physiotherapy for greater improvement. Subacromial injection may be used as an alternative to glenohumeral injection. Ultrasound guidance would also be useful.

Keywords: Adhesive capsulitis, corticosteroids, injection

When seems one thing but is another

Joana Palmira Magalhães

Centro de Saúde Miranda do Douro - ULS Nordeste, Bragança, Portugal

Background & AIM: Hypoglycemia is a complications of diabetes therapy, especially if the patient is medicated with insulin or a sulfonylurea. Each person's reaction to hypoglycemia is different, the signs and symptoms can be autonomic: sweating, shaking, hunger or palpitations and neuroglycopenic: difficulty concentrating, confusion, drowsiness, odd behavior (irritability, aggressiveness), speech difficulty or coma.

We seek to expose a case report that shows how the symptoms of hypoglycemia can be mistaken by psychiatric disease.

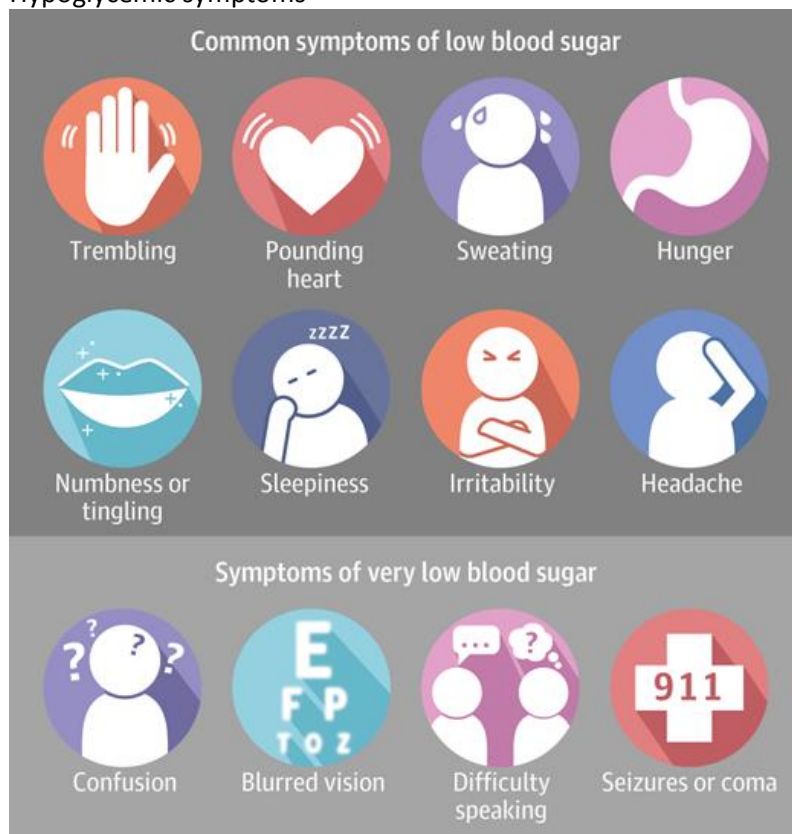

METHOD: Man, 66 years, history of insulin-dependent diabetes and dyslipidemia, brought by medical emergency service, to the urgency service, with sudden onset of disorientation, sporadic aggression and inappropriate speech. After observation was performed objective examination and cranial CT scan. With a normal physical examination described, was sent for reevaluations by different medical specialties, where chest X-ray and blood test were requested. The specialist evaluated the brain CT scan and decided that the changes detected didn't justify the clinical state. Than requested observation by psychiatry.

RESULTS: At the psychiatry urgency the patient was restless, confused, aggressive and with incoherent speech. After observation of the tests results, was measured capillary glucose and resulted in 36 mg/dl. Therapeutic approaches were applied to treat hypoglycemia and the patient quickly recovered consciousness, orientation, calmness and cooperation.

CONCLUSIONS: Hypoglycemia secondary to the use of insulin or insulin secretagogues is important to recognize and treat as early as possible. Individuals may need to adjust their insulin regimen to lower the risk. The frequency and severity of hypoglycemia has a negative impact on quality of life, promotes fear of future hypoglycemia and could be associated with increased mortality. It is related with reduced self-care and poor glycemic control. Therefore the prevention of hypoglycemia and its prompt and effective treatment is essential.

We present a poster showing types of abdominal aneurysm on adults, based on a case we managed to detect in our primary care center. A 67 years-old male with a history of hypertension, diabetes mellitus type II and ischemic heart disease, who consulted referring hypogastric abdominal pain of rapid onset with nausea but no vomiting or diarrhea. While visited he suffered a syncopal event with persistent hypotension even to volume replacement, it decided to transfer him to the Emergency Care of our reference Hospital. Once arrived there, he had a CT-Scan imaging that showed aneurysmal rupture of the left common iliac artery.

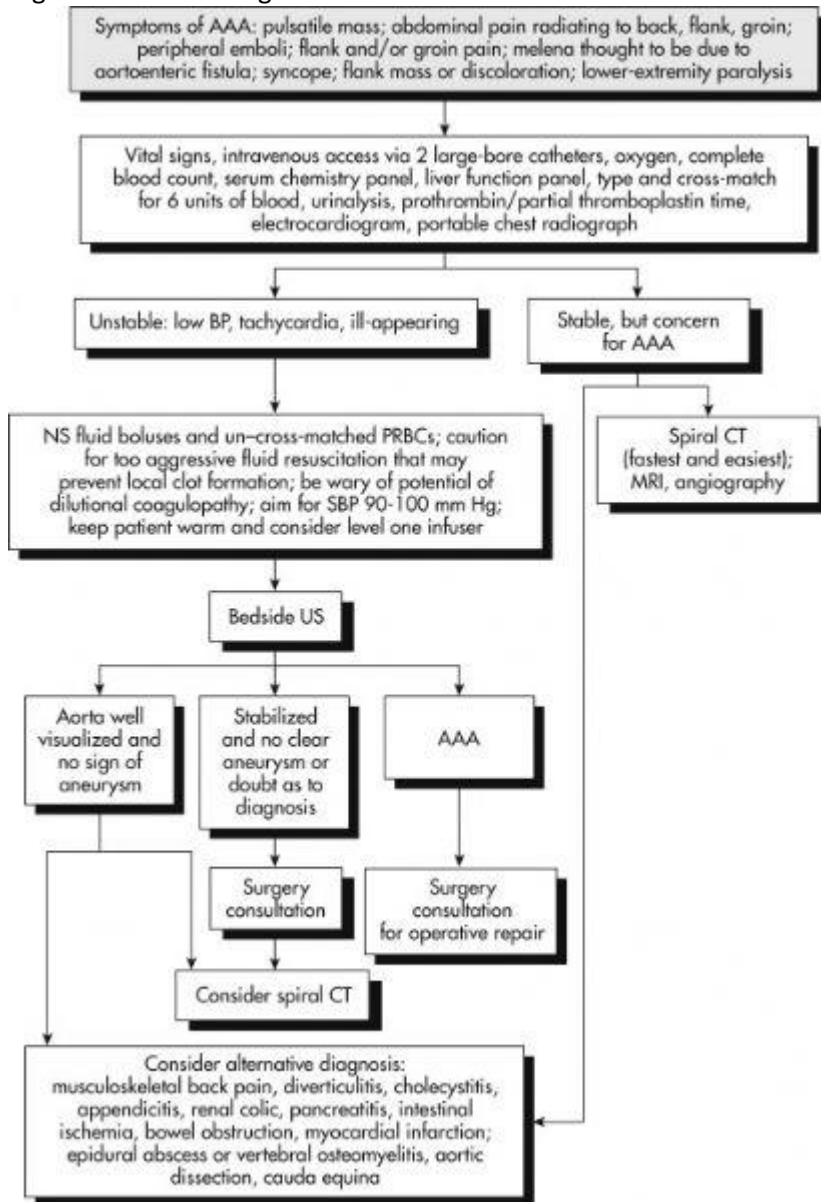

The Intensive Care Unit received him in a volumic shock state. It was managed to maintain blood pressure levels after vasoactive support with noradrenaline. Transferred to the vascular surgery department for an urgent intervention with a Dacron By-pass of the left common iliac artery and the left external iliac artery. Once stable he was discharged from the hospital and we attended him for a follow up visit in our consult. From a primary care point of view this case shows us that even though a life threatening condition could be overlooked easily, the suspicion and rapid management could save lives.

Keywords: aneurysmal rupture, hypotension, aneurysm, volumic shock.

A case of post-infectious irritable bowel syndrome in a young patient

Background

Irritable bowel syndrome is a common gastrointestinal disorder, within the large group of people affected, there is a small subgroup whose symptoms begin suddenly after what appears to be gastroenteritis and is termed post-infectious irritable bowel syndrome.

Both host and pathogen related factors, such as pre-existing psychological disorders and duration of initial infection, have been associated with an increased risk for the development this pathology. Clinical management of this condition encompasses dietary, lifestyle advice and pharmacological therapy.

Aim

Increase the knowledge of family doctors about post-infectious irritable bowel syndrome.

Method

Clinical case presentation.

Results

The subject is a 26 year old male, works as a dentist and has no relevant medical antecedents and as surgical antecedents he was submitted to an appendectomy.

He recurred twice to emergency department in June 2014 with the complaints of nausea and vomiting for more than 20 days, the blood test was normal and he was diagnosed with gastroenteritis and was medicated with Metoclopramide and discharged.

Despite this medication he recurred to the hospital in August 2014 maintaining complaints of nausea, generalised and recurrent abdominal discomfort, urgency and frequent bowel movements with less consistent stool. He was then referred to a specialized gastroenterology consultation for further study. The stool and blood exams, endoscopy with biopsies were negative. He was then medicated with Alprazolam SOS and Domperidone SOS and referred to his family doctor for treatment maintenance and following.

Conclusions

The family doctor has a major role in the treatment of people with irritable bowel syndrome. The patients should be given information that explains the importance of self-help in effectively managing their condition, which includes information on general lifestyle, physical activity, diet and symptom targeted medication.

CHRONIC PAIN OR DEPRESSION? After all it was a Neurinoma. A case-report

Maria Manuela Bernardo, Mariana Gayo, Ana Beatriz Figueiredo, Ana Magalhães

USF das Conchas, Lisbon, Portugal

BACKGROUND: Depression is the most common psychiatric illness in Primary Health Care and almost two-thirds of patients present somatic symptoms such as chronic pain. To diagnose depression, the General Practicer (GP) has to distinguish somatization from an organic cause of pain.

Neurinoma is a slow-growth, benign tumor of CNS, which affects patients mainly between the third and sixth decades, that can mimic an osteoarticular pain and it is very often incidentally diagnosed.

CASE PRESENTATION: A 46 year old woman with a diagnosis of major depression since she was 20, also followed in Psychiatric, and history of suicide attempted. The patient had a history of cervical pain since 2012 affecting both upper limbs, associated with decreased muscle strength and bilateral paresthesias. Meanwhile, she was medicated with analgesic therapy and long-term physiotherapy without significant improvement.

After multiple visits to the doctor, a CT-scan was performed in 2014, which showed a mass of unknown etiology located between C3-C4. The patient was referred to Neurosurgery for further investigation, and the final conclusion was a cervical neurinoma presenting with spinal cord compression that could justify her symptoms. Months later, the patient was submitted to surgical excision of the tumor and she began a slow recovery with symptoms improvement. Her depressed mood also improved considerably.

COMMENT: Due to the complexity of clinical manifestations of depression, the diagnosis of other important pain causes can be challenging on these patients. We intend to draw your attention to the importance of clinical history and physical examination when consulting since the role of the GP is to provide adequate clinical and imagiologic investigation to all patients keeping in mind less frequent diagnoses such as neurinoma, that often go unnoticed causing distress to the patient.

Sarcoidosis is an inflammatory disease characterized by non-caseating granulomas that can be present in diverse organ system. We report a case of sarcoidosis with bilateral optic neuritis as the initial manifestation.

A 31-year-old caucasian woman was seen in the emergency ophthalmology department because of bilateral sudden vision loss. She also had a cold with runny nose, fever and malaise.

Full physical examination was not pathological; laboratory testing showed leukopenia, without anemia or thrombocytopenia; negative tuberculin skin test; posteroanterior chest radiography with the presence of bilateral hilar adenopathy, and right paratracheal node enlargement.

The eyes examination included the following elements: general inspection (no erythema, no tearing, no proptosis, no ptosis, but light sensitivity), visual acuity (which was decreased, 0.1 for the right eye and 0.2 for the left eye), evaluation of the extraocular movement (which was right), confrontation visual fields, pupils (were symmetrical, reactive to light, pupillary reflex preserved), fluorescein test negative, intraocular pressure in both eyes was 12, slit lamp exam (with examination for red-reflex symmetry), ophthalmoscopic examination (minimum papillitis with hyperemia and swelling of the disc, blurring of disc margins, and distended veins).

The patient was admitted, and the study was completed with nuclear magnetic resonance, and Gallium-67 scintigraphy (showing a pattern of diffuse uptake). Transbronchial biopsy and histopathology examination were performed to confirm the diagnosis: the presence of granuloma was confirmed (a focal, chronic inflammatory reaction formed by the accumulation of epithelial cells, monocytes, lymphocytes, macrophages, and fibroblasts). The patient began taking glucocorticoids and her visual acuity was recovered. She was discharged 4 days after admission, has done well after discharge from the hospital and is without any known sequelae.

Investigating the seasonal trend of stroke frequency in a rural area

Constantinos Mihas¹, Andreas Katrapas¹, Aikaterini Mpahara¹, Maria Rifouna², Eleni Petropoulou², Panagiotis Andriopoulos², Anargiros Mariolis²

¹Health Centre of Areopolis, Mani, Greece

²General Hospital-Health Centre of Kimi, Evia, Greece

Background & AIM: The seasonality in the appearance of strokes has been discussed in the international literature and the results are not considered absolutely clear taking into account the small number of relevant publications. The purpose of this study was to investigate the trend in the frequency of strokes, using data coming from a rural area in the second larger island of Greece, Evia.

METHOD: For the purpose of analysis, the data used were pooled from the admission records in the General Practice/Internal Medicine Department of the local public hospital-health centre from 1/9/2011 to 08/31/2014.

This hospital is the only primary and secondary health care provider, serving a population of approximately 10,000 residents of eastern Evia. The incidents were classified as stroke, regardless of their pathology (ischemic or bleeding) or if they were transient or not. Statistical analysis included the Mann-Kendall and seasonal Mann-Kendall statistics. Statistical package R v.3.1.1. © The R Foundation for Statistical Computing was used.

RESULTS: The overall relative frequency of strokes was 9.2%. According to the results of the analysis, no time trend was observed when the data were grouped by day of week or year (Kendall's tau: -0,195, -0,401, p-value: 0,649, 0,092, respectively). There was however a significant trend when the data were grouped by month of admission weighting for seasonality (Seasonal Mann-Kendall test, Kendall's tau: -0,636, p: 0,001)

CONCLUSIONS: These initial results suggest a time trend in the frequency of strokes at least in this sample, forming the basis for correlation with environmental factors in the future in order to further illustrate their frequency pattern.

Doctor, I have a bad taste in my mouth for several months

João Rocha Moutinho, Diana Almeida Ferreira

Unidade de Cuidados de Saúde Personalizados da Mealhada

INTRODUCTION: Mouth cancer is one of several types of cancer grouped in a category called head and neck cancers. Oral cancer consistently ranks as one of the top ten cancers worldwide, with broad differences in geographic distribution. They represent approximately 5% of cancers in men and 2% in women. Some factors that can increase the risk of mouth cancer include tobacco use of any kind, heavy alcohol use and papillomavirus. More than 90-95% of oral cancers are squamous cell carcinoma or one of its variants. They typically presents as a persistent mass, nodule, or indurate ulcer. The three most common sites of involvement are tongue, lip and floor of the mouth.

CASE: ♂, 69 years old, caucasian, retired, belonging to a family in phase VIII of Duvall cycle. Presents hypertension and dyslipidemia, treated with simvastatin 40 mg and with valsartan 160mg + hydrochlorothiazide 12.5 mg. Smokes 20 cigarettes per day since he was 25 years old. One day consulted his family doctor because a bad taste in the mouth for the last couple of months. His medical inspection showed a voluminous tumefaction under the right jaw. The computed tomography of the salivary glands showed "on the anterior pole of the right submaxillary gland one nodule with 34x31.7mm compatible with a right submandibular gland tumor". He was sent to a Hospital, to be consulted for maxillofacial surgery with the final diagnosis a squamous cell carcinoma on the right paving of the floor of the mouth. The surgery consisted on a median mandibulotomy, right hemipelvectomy, ventral glossectomy and extensive cutaneous reconstruction. One year before surgery the patient is functionally fully recovered, with an annual consult in maxillofacial surgery.

This case illustrates that oral cancer is sometimes asymptomatic initially, so oral screening is useful for early diagnosis on high risk patients.

When investigating back pain

David Tomaz Rodrigues¹, Marta Lopes¹, Susana Grilo Loureço¹, Nídia Nunes¹, Teresa Pereira Leite²

¹USF Planície, ARS Alentejo, Évora, Portugal

²USF Alcáides, ARS Alentejo, Montemor-O-Novo, Portugal

Introduction

Low back pain is a very common cause in a family medicine consultation. It often become disabling, requiring analgesic treatment and complementary diagnostic procedures for etiological investigation.

Case description

Patient male, 50 years old, Caucasian, metallurgical, inserted into nuclear family in the phase VI of Duvall Cycle. Previous history of hypertension, dyslipidaemia, inguinal hernia and carpal tunnel surgeries.

On 2014, July 25th, he uses to open consultation for left low back pain, with a mechanical rhythm, over 10 days of evolution, there's no history of trauma. It was medicated with naproxen, esomeprazole and thicolchicoside.

In the next six days, he uses for two more times the open consultation with left back pain, with more intensity at morning, accompanied by left upper quadrant pain. Physical examination always unchanged. Complementary examinations were applied and he was referenced to the emergency service (ES). In the ES has been described a pain in the left rib cage and it was detected an anaemia of 12g/dl of haemoglobin. He was treated with diclofenac and acetaminophen.

He returned to consultation on August 20th, 2014, keeping complaints, with the result of complementary examinations, with anaemia (Hb - 12.1g/dL); high sedimentation rate (121); Total protein 9.1 and globulin 41.2. It were requested immunoglobulins (A / G / M); Beta2-microglobulin, Rx chest and lumbar spine CT, associating Metamizol and thicolchicoside the proposed therapy.

No improvement appealed to the US having been admitted to etiological investigation and was diagnosed multiple myeloma after viewing lytic lesions of ribs and vertebrae lumbar L1 and 3.3% plasma cells of medullary

blood during hospitalization. He died after 5 months.

Discussion

Although there is often a range of low back pain causes, the family physician must be aware of diagnostic hypothesis, the seriousness require timely and targeted intervention.

Keywords: low back pain; multiple myeloma

Paraneoplastic thromboembolism in lung cancer patient

Marija Marjan Zaric, Bojan Zoran Pavkovic, Marina Slobodan Brankovic
Department of general practice, Health Center "Dr Simo Milosevic", Belgrade, Serbia

CASE:

A 63-year old female, without comorbidities, smoker for over 40 years, presented to GP with weak cough, haemoptysis and sudden onset of life-threatening dyspnea.

Patient was hospitalized through the emergency department in the regional oncology center.

MSCT pneumoangiography showed thrombotic masses in main arteries of lower right and left lobes of the lung, and their segment and subsegment branches. Anticoagulant therapy for pulmonary embolism was administered and treatment was followed by quick improvement of general condition.

CT scan: tumor in the left lung with metastases in right lung, with enlarged paraaortic lymph nodes.

Bronchoscopy: adenocarcinoma of the lung.

Due to thrombosis of the main arteries of lower lobes, patient was initially treated with anticoagulant therapy (Nadroparin, then Acenocoumarol), and after stabilization of thrombotic masses, chemotherapy was started.

Fifteen days after 4th chemo cycle, patient came to GP because of deterioration of general condition, fever up to 39.4°C and dyspnea. Laboratory results showed presence of infection and elevated D-dimer: 2933ng/ml. Patient was hospitalized.

Chest X-ray: shadow of soft tissue consistency in the middle region of left lung with left hilar enlargement.

CT scan showed decreased size of tumor mass, but also pneumonic infiltration of the laterobasal and posterior regions of left lung. The patient was treated for bronchopneumonia with pulmonary re-thrombosis, and after antibiotic and intensified anticoagulant therapy (Acenocoumarol was replaced with Nadroparin), general condition and symptoms was improved.

Doppler ultrasound showed some old organized thromb in pelvic vessels, and revealed new thrombosis of deep veins of right arm, and both legs from the position of bifurcation of iliac vein.

Two months afterwards CT scans of the lung and brain were done – brain metastases were confirmed, and also worsening of pulmonary thromboembolism. Palliative irradiation of brain is in progress.

Keywords: lung cancer, paraneoplastic thromboembolism, anticoagulant therapy

Cold Urticaria: Report of A Case

Duygu Ayhan Başer¹, Serdar Başer², Elçin Katı³, Aybuke Demir³, Zeynep Sayın Dinçer³, Gökhan Dinçer⁴

¹department of family medicine, Kocaeli Derince Public Health Center, Kocaeli, Turkey

²department of ear nose throat diseases, Derince Training and Research Hospital, Kocaeli, Turkey

³department of family medicine, Ankara Numune Training and Research Hospital, Ankara, Turkey

⁴department of family medicine, Ankara Training and Research Hospital, Ankara, Turkey

INTRODUCTION: Cold urticaria is a skin reaction to cold which is subtype of physical urticaria. The severity of cold urticaria symptoms varies widely; some people have minor reactions to cold, while others have severe reactions. Swimming in cold water is the most common cause of a whole-body (systemic) reaction. Its diagnosis, mainly clinical, is based on the clinical history of urticariform exanthema and/or angioedema after skin exposure to cold stimuli, confirmed by the “ice cube” test and by the exclusion of other diseases.

We emphasized the importance of the early diagnosis of this disease especially in primary care with this case.

Case Presentation: 14-year-old male patient was admitted in family medicine clinic with complaints of urticaria with dyspnea after exposure to cold sea water. He had a personal history of asthma and allergic rhinitis from the age of 3; controlled with inhaled corticosteroid, montelukast and salbutamol treatment in crises. He had a family history of asthma in his mother and sister. 4 years ago the patient presented generalized urticariform exanthema with dyspnea, pallor, nausea and dizziness, after cold sea water exposure. These symptoms disappeared spontaneously. A positive “ice cube” test (in the 3rd minute) and analytical tests with no relevant changes (except the presence of peripheral eosinophilia (1100/ μ L) and an increase in the IgE (310 KU/L)), led to the diagnosis of acquired idiopathic cold urticaria. It was recommended that she avoid exposure to cold and undergo pharmacologic treatment with a second generation antihistaminic.

CONCLUSION: Cold urticaria can be associated with severe systemic symptoms. The early diagnosis of this disease especially in primary care is very important in order to prevent potential lifethreatening situations.

DVT, clinical findings meet the guidelines

Luis Magalhaes, Sara Moreira, Gabriela Poças
USF Leça - ULS Matosinhos, Porto, Portugal

BACKGROUND: 33 year old man, caucasian.

Obesity, smoking history. Unknown allergies. No usual medication.

AIM: Reflection on the clinical practice aiming to improve health care's quality.

METHOD: Case report.

RESULTS: Patient attends physician with a sudden left calf swelling. Initially interpreted as superficial thrombophlebitis, was sent home with relief medication.

Two days later, he attends his family physician. He mentions no trauma history. The clinical findings included assymmetric edema, warmth, tenderness and a palpable, indurated, cordlike venous segment. Assuming deep vein thrombosis (DVT), the doctor referred him to the hospital, where an ultrasonography of the lower limb showed no signs of thrombosis. Five days after the initial presentation of the symptoms, the patient consults again with his family physician, whom after consulting the ultrasonography report, tranquilizes the patient prescribing compression socks and scheduling a new ultrasonography.

The next day, the patient was admitted at the hospital urgency with acute abdominal pain. While waiting for the initial workup he developed chest pain, shortage of breath and oxygen desaturation. Further exams revealed portal vein thrombosis and a massive pulmonary embolism.

CONCLUSIONS: Evidence-based literature supports the practice of determining a clinical pretest probability of DVT (eg. Wells). In patients with intermediate to high pretest probability of DVT, ultrasonography is recommended. If negative, the ultrasonography should be repeated within a week. Here, a pulmonary embolism occurred before the referred time. Distal DVT (infra-popliteal) are less likely to progress than proximal DVT's. In these cases, ultrasonography is more operator-dependent and less sensitive than proximal vein examination. Changing from a expert-oriented system to a guideline-oriented system allows a standardization of the health care provided, but may incur in failures in the recognition of individual differences between patients and between courses of disease. Therefore, the physician should look for an individualized approach to each patient.

When seizures are disguised

Mariana Almeida Pinto Moura Relvas, Margarida Pereira, Nina Monteiro, Maria Do Carmo Gonçalves
Unidade de Saúde Familiar PortoCentro, Porto, Portugal

BACKGROUND: An epileptic seizure is a clinical event presumed to result from an excessive neuronal discharge. Nearly 5-10% of the population will have at least one seizure. The clinical symptoms may include impaired consciousness and motor, sensory, autonomic, or psychic events. Patients with seizures may report a prodrome, including mood changes, sleep disturbances, lightheadedness, anxiety, irritability and difficulty concentrating. Automatism may also be present, as nonpurposeful, stereotyped, and repetitive behaviors. Due to the variety of clinical manifestations, misdiagnosis is common in a setting of primary care. There must be a high level of suspicion amongst general practitioners to ensure a correct diagnosis. **Clinical CASE:** Female, 61 years old, 6th grade, residing in Porto, house-wife, divorced. The patient is a smoker and has a history of dyspepsia, anxiety, COPD and edema of the larynx with dysphonia accompanied by an ENT. On the 3rd of September of 2013, the patient comes due to a feeling of throat obstruction with 1 month of evolution and aphonia. She was referred to the Hospital. On the 13th, the patient recurred again by dysphagia and fear of a thyroid condition. The ENT didn't detect a problem and she left with advice for vocal rest and a benzodiazepine. On the 4th of October, she returned with an intense feeling of throat obstruction, dyspnea and dysphagia. Because of the anxious component of the patient, she was given a benzodiazepine with improvement. An Endoscopy was requested. On the 23rd of November, the patient went to the ER due to lipothymia and CET. She was observed by a Neurologist and diagnosed with vascular epilepsy. She medicated with Lamotrigine and clopidogrel. On the 20th of December we observed the patient and the symptoms had stopped. **DISCUSSION:** This case focuses on the importance of a patient centered approach, characteristic of Family Medicine. It demonstrates the need for the general practitioner to be aware of less frequent pathologies, in order to conduct a good differential diagnosis.

Statins and Sun: a bad relationship - a case report

Diana Vaz De Miranda¹, Cátia Pereira Da Silva², Ana Sofia Alves¹, Olga Pereira³

¹Unidade de Saúde Familiar S. Nicolau, Guimarães, Portugal

²Unidade de Saúde Familiar Aqueae Flaviae, Chaves, Portugal

³Department of Dermatology, Centro Hospitalar do Alto Ave, Guimarães, Portugal

Background & AIM: Drug-induced photosensitivity is determined by the capacity of some medications to modify an individual's sensitivity to solar radiation or artificial light and present clinically as dermatoses in the exposed areas. Photosensitivity reactions may result from commonly used systemic medications but because of their rarity, they are often clinically neglected. With this report the authors intend to describe a case of photosensitivity reaction to statins.

METHODS: Data were gathered from clinical records using the electronic medical record system SClinic®.

RESULTS: A 39-year-old male was sent by his Family Doctor to the Dermatology Department due to a non pruriginous facial erythema, with escalation in the last 6 months. The patient had a personal history of Psoriasis since he was 16 years-old, treated with topic medication. About a year ago, in a routine appointment, he was diagnosed with Hyperlipidemia, Hypertension and Hyperuricemia and medicated with Symvastatin 20mg id, Lisinopril 5mg id, Allopurinol 100mg id. Physical examination showed a violaceous erythema of the exposed areas of head and neck, drawing the neckline and also a descamative erythema of the back of the hands and wrist. The characteristics and distribution of these lesions are compatible with a photosensitive reaction. After a rigorous anamnesis and therapeutical review, the most likely diagnostic hypothesis was Drug-induced Photosensitivity by Symvastatin. The anti-lipidemic was suspended and a sunscreen with a sun protection factor of 50+ was prescribed, with gradual clinical improvement.

CONCLUSIONS:

When dealing with a skin photosensitivity reaction, it is important to know the most commonly implicated drugs.

Diagnosis of photosensitivity due to statins requires a high degree of suspicion but since these are one of the most worldwide prescribed drugs, clinicians should be aware of this side effect.

Urinary tract schistosomiasis: a case report

Ana Sofia Alves, Diana Vaz De Miranda, Carla Costa, Francisca Caetano, Cláudia Teixeira, Luísa Pinto
Unidade de Saúde Familiar S. Nicolau, Guimarães, Portugal

BACKGROUND: Urinary schistosomiasis caused by *Schistosoma haematobium* worms is endemic to tropical regions where it is the most common cause of hematuria. However, the intermediate snail hosts *Bulinus truncatus*, have been described in Portugal, Spain, Sardinia and Corsica. It can induce lesions in the urinary and genital tract epithelia, as eggs pass through or get trapped in the tissue. With this report the authors intend to describe a case of *S. haematobium* infection occurring in an otherwise asymptomatic woman.

METHODS: Data were gathered from clinical records using the electronic medical record system SAM®.

RESULTS: A 51-year-old woman with hypertension and dyslipidemia showed a *S. haematobium* infection in a routine urine sediment. Microscopic examination of the urine revealed the presence of red blood cells and showed live and dead ova of the parasite. She was afebrile and had no urinary symptoms. Complete blood count was normal without eosinophilia. She reported not having traveled outside Portugal. No *S. haematobium* eggs were found in the urine of the other family members. Because of the recognised risk of urogenital complications the patient was therefore referred to the Urology department for further investigation.

CONCLUSIONS: Urinary schistosomiasis is not endemic in Europe, although sporadic cases have been described. Most individuals with schistosomiasis infection are asymptomatic and have a low parasite burden, but severe damage of urinary tract organs can occur. Since the competent intermediate host is established in Portugal, this entity should be considered as differential diagnosis, especially in patients presenting with hematuria.

Key-words: *Schistosoma haematobium*, urinary tract, asymptomatic haematuria

Keywords: *Schistosoma haematobium*, urinary tract, asymptomatic haematuria

Rare complications of acute otitis media in an elderly woman: report of a case

Duygu Ayhan Başer¹, Serdar Başer², Elçin Katı³, Meltem Koç⁴, Hilal Aksoy⁵, Rabia Kahveci³, Adem Özkara³

¹department of family medicine, Kocaeli Derince Public Health Center, Kocaeli, Turkey

²department of ear nose throat diseases, Derince Training and Research Hospital, Kocaeli, Turkey

³department of family medicine, Ankara Numune Training and Research Hospital, Ankara, Turkey

⁴department of family medicine, Mamak Public Health Center, Ankara, Turkey

⁵department of family medicine, Etimesgut Cancer Early Diagnosis, Screening and Education Center, Ankara, Turkey

Introduction

Acute otitis media (AOM) is defined as an inflammatory process of the middle ear associated with an effusion. AOM is a frequent condition seen in primary care. It often appears with otalgia, fever and headache after an upper respiratory infection. Serious complications such as mastoiditis, meningitis are rare but can be life-threatening.

Case report

A 85 year-old woman with hypertension, type 2 diabetes mellitus, was admitted in family medicine clinic with complaints with left for 5 days. Physical examination led to a diagnosis of AOM, a treatment with amoxicillin 1000 mg/ clavulanate 125 mg every 8 hours was prescribed. 1 day later, the patient developed antibiotic intolerance, for this reason the antibiotic was changed to cephalosporin and oral corticosteroids were given. 2 days later due to deterioration, the patient was sent to the ear nose throat clinic. A cranial CT scan revealed a bilateral AOM, bilateral otomastoiditis and left maxillary sinusitis. She was admitted to the hospital and broad-spectrum intravenous antibiotics were given. After 3 weeks, she was discharged with wellness.

Conclusion

Elderly people especially diabetics are at a higher risk of developing complications of AOM. A comprehensive physical examination and follow up are very important in primary care to prevent or early detect the complications.

Case of Bonzai Intoks Tracking and Management in The Emergency Department

Nadiye Karabulut¹, Sündüs Görükmez¹, Seçil Günher Arıca¹, Selman Yeniocak²

¹Haseki Eğitim ve Araştırma Hastanesi, Aile Hekimliği Kliniği, İstanbul

²Haseki Eğitim ve Araştırma Hastanesi Acil Servis Kliniği, İstanbul

Background and AIM:

Synthetic kannabioids (SK) have psychoactive effects similar with cannabis. Overall abroad "Spice," "K2", while in Turkey "Bonzai" or "Jamaica" is released. In this study is aimed to determine common symptoms, clinical findings and lab results in cases of bonzai intox.

METHOD: Bonzai intoks 61 cases that brought to Haseki Training and Research Hospital Emergency service between the months of November to August of 2014 were analyzed retrospectively. The case of age ranging between 15 to 53, were found to be the most common range of 20-25 years old (70%). Arrival Glasgow coma scale (GCS): in 88.4% (n = 54) 8 points (E2, V2, M4), in 10% (n = 6) 9 points (E2, V2, M5), 1.6% (n = 1) in the 4 points (E1, V1, M2) were evaluated. The Pupil reflexes in 90% (n = 52) fixdilate, in 10% (n = 9) were normal. Venous blood glucose average of 120 ± 29 mg / dl and were hyperglycemic. The average blood gas pH was found to be 7.35 ± 0.07 . In all cases, EKG, Troponin-I coagulation, Kidney, liver function tests and blood electrolyte levels were normal. A case was intubated. All patients were followed closely for at least 24 hours and was given support treatment. After the treatment; GCS 15 points (E4, V5, M6) were evaluated in all cases.

Results and DISCUSSION:

SK type and quantity of the substances, frequency and use of personal susceptibility may cause to toxicity and can affect all systems of the body. All patients were followed closely for at least 24 hours, was given to the support treatment and was discharged uneventfully. Bonzai intoxication can lead to death. So should be kept in mind that the person who brought the change of consciousness especially young people may have used these substances.

ANCA MPO Vasculitis: a long diagnostic journey

Nuno Guerra, Joana Almeida

Health Unity Camélias, Health Center Porto VII

Background - Microscopic polyangiitis (MPA) is a small-vessel necrotizing vasculitis with involvement of the glomerular and pulmonary capillaries. It represents a diagnostic challenge due to its nonspecific symptomatology and insidious evolution.

Objective – Report of a case of ANCA MPO vasculitis, highlighting the role of the general practitioner (GP) in the diagnosis and management of these diseases.

Description – 67 years old man with a personal history of chronic gastritis. He presented to his GP in an urgency consultation with a one-month clinical picture of dyspnea to small efforts, dry cough, abdominal discomfort and anorexia. Laboratorial exams were carried out, displaying a mild anemia (11,8 g/L), and a spirometry was performed, with a result compatible with asthma. Inhaled corticosteroids were started. One month later he returned due to maintenance of abdominal discomfort, although exhibiting improvement of the respiratory symptoms. A colonoscopic examination was awaiting scheduling at this time. Two months later an episode of haemoptysis motivated a visit to a private pulmonologist, with the patient undergoing a lung CT scan, with no pathological findings. Ten days later he was admitted to the Emergency Department exhibiting rectal bleeding, with colonoscopy revealing signs compatible with acute vasculitis. Severe anemia and acute renal failure were detected, with requirement of hemodialysis. Laboratorial examination revealed ANCA MPO positivity, and the diagnosis of ANCA MPO vasculitis with rapidly progressive acute renal failure was assumed. He was initially treated with high dose corticosteroids and cyclophosphamide, with clinical improvement but without renal function recovery, and is currently under maintenance therapy with oral corticosteroids and azathioprine, with follow-up by his GP and nephrologist.

DISCUSSION: Small vessels vasculitis are multisystemic disorders with nonspecific symptoms as manifestations, leading to a delay in the diagnosis. This case emphasizes the importance of GP awareness to these early and undifferentiated presentations.

Keywords: ANCA MPO Vasculitis

sOap – Physical Examination: Abdominal pain with deep palpation of left hypochondrial and epigastric. No defense

soAp – Weakness/tiredness general, Abdominal pain

soaP – Colonoscopy still waiting scheduling

July

An episode of haemoptysis motivated a visit to a private pneumologist. The CT Scan didn't show any pathological findings.

Some days later the patient phoned his Family Physician because he was having rectal bleeding. He was then advised to go to the hospital urgency. He was admitted in the emergency room presenting with rectal bleeding, and the emergency colonoscopy revealed signs of vasculitis. He was hospitalised with a severe anemia (7 Hb/g) and in acute renal failure, so he started hemodialysis. During the investigation the exams revealed ANCA and MPO positive values, suggesting a small vessels vasculitis ANCA and MPO positive, with rapidly progressive acute renal failure.

At this moment he is still on hemodialysis.

Protocol of Clinical Action in Primary Attention Care of the Traumatism of the Elbow

Leticia Sierra Martinez¹, Iker Sierra Martinez², Rosario Martine Fuerte¹, Natalia Sanz Gonzalez³

¹Valladolid Este Primary Assistance Gerency, Castile and Leon Sacyl, Valladolid, Spain

²Traumatology Department, Hospital of Medina de Campo (Valladolid), Spain

³Parquesol Senior Center, JCYL Social Serices Gerency, Valladolid, Spain

Background

Centring the professionals of primary care on the managing of the Traumatism of the elbow

Methods: Develop a Protocol of Clinical Action in Primary Attention Care of the Traumatism of the elbow

RESULTS: So much the different accidents (of traffic, labor, fallen, etc.) as the sports practice they carry, in some occasions, injuries in the elbow Though many of them, specially the bony fractures or the affections you will articulate they need a hospitable treatment and a follow-up on the part of an orthopedic surgeon, it is necessary that the doctor of primary care knows the semiology of the most serious traumatic and frequent disease, as well as the different therapeutic options. In addition, often, the patient appeals his doctor of family in search of advice and information in reference to his recovery, sequels, etc., without forgetting the follow-up of the labor disability that often he accompanies on the injury. But, undoubtedly, it is in the injuries of soft parts where paper of the family doctor has a more important paper, not because it is traumatism in general serious, but because they are injuries that, if they are not solved adequately, can concern seriously the quality of life of the patient.

CONCLUSIONS: The authors propose this protocol with the intention of centring to the professionals of primary care on the managing of the traumatism of the elbow of major demand on the consultations, across "keys" or "keys" for his correct diagnostic suspicion, complementary necessary tests, signs of alarm of complications, initial attention, how and when to derive to the specialist, treatment of choice, time of immobilization and type of later rehabilitation, as well as the time foreseen of labor disability of his patients with traumatism in the anatomical area of the elbow

Keywords: Primary Attention Care; Traumatism of the elbow; Protocol of Clinical Action.

Case report: PULMONARY EMBOLISM

Rümeysa Macit¹, Gökçen Külahlı¹, Semih Başçı², Abdulkadir Koçanoğlu², Zuhal Aydan Sağlam¹, Banu Mesçi²

¹Department of Family Medicine, Istanbul Medeniyet University

²Department of Internal Medicine, Istanbul Medeniyet University

INTRODUCTION:

Pulmonary embolism is a common and potentially lethal disease. In spite of advanced diagnostic techniques, diagnosis is often delayed. This paper aims to remind of the possibility of pulmonary embolism which is facilitated by oral contraceptives and postoperative immobilization.

CASE:

A 32-year-old female patient presenting with stomach pain, epigastric burning and cough for five days was prescribed for gastroesophageal reflux but was readmitted to the emergency service with additional palpitation and dyspnea. In her physical examination, she was pale: her BP was 90/50 mmHg and pulse rate was 95/min. Her respiratory system examination revealed normal. No pathology was observed in PA chest radiography and electrocardiogram. The only pathologic value was Hb: 9.9 g/dL; the other biochemical values were normal. According to her medical history, she had been using OC for three months and had a cosmetic breast operation 20 days ago. Her detailed history revealed that OC was not discontinued before and after operation. This information led us to further analysis as serum D-dimer and fibrinogen levels for preliminary diagnosis of pulmonary embolism which were recorded as >20 ng/ml and 508 mg/dL respectively. Echocardiography and thoracic CT angiography were both consistent with pulmonary embolism due to the thrombus on bilateral main pulmonary artery. There was no pathologic source of emboli in bilateral lower extremity venous Doppler ultrasound examination. Drugs used by the patient were discontinued and warfarin sodium was initiated. At the 14th day of admission she was discharged from the hospital with chest disease monitoring.

DISCUSSION: OC use may cause oncological and cardiovascular risks by affecting directly to blood vessel wall and hemostatic system. Long term immobilization may also cause embolism due to deep vein thrombosis. Pulmonary embolism is difficult to diagnose if it is not kept in mind for differential diagnosis in patients at risk. This case emphasizes the importance of getting detailed medical history when having elective or urgent surgical decisions.

P-0327

D-Dimers, a strong negative predictive value and a strong positive treatment factor in acute situations with suspected pulmonary embolism?

Gerard Nguyen, Camille De Franceschi, Dominique Le Mout

Cabinet Marcel Monny Lobe, Soisy Sous Montmorency, France

Plasma D-Dimer measurement is commonly used as the first test in patients suspected of having acute pulmonary embolism (PE). Specificity is typically between 40% and 60%, leading to a high rate of false positive results.

Several factors are associated with positive D-Dimer results.

We reported 2 clinical cases as landmark and complex situations seen in primary care where D-Dimer measurements have been contributive for treatment decision in suspicion of PE.

Mrs J.P. 88 yo, having a pleural mesothelioma with chemotherapy abstention was treated by antibiotics for a common pulmonary bronchitis. One week after the recovery, she complained of a thoracic pain and a mild dyspnea without fever and an oxygen saturation of 92%. Blood analysis showed a normal white cells count, a CRP=118 mg/L and D-Dimers=3143 ng/mL. She refused to be hospitalised. Left pleural syndrome was persistent contra-indicating contributive thoracic imaging. Ambulatory treatment by subcutaneous Tinzaparin 10.000 UI daily for 1 month was undertaken. D-Dimers kinetic showed an important decrease during one month (2246 mg/mL at day 15 and 890 mg/mL at 1 month) and symptoms disappeared.

Mrs J.R. 87 yo had an isolated persistent nocturnal cough after 5 days of symptomatic treatment. She became dyspneic without fever and an oxygen saturation of 90%. Blood count was normal, CRP=1 mg/mL and D-

Dimers=3069 ng/mL. She refused to have thoracic imaging because she had to care her husband at home. She accepted to be treated at home with Tinzaparin 10.000 UI daily for one month. D-Dimers kinetic showed a significant decrease over one month D-Dimers=437 ng/mL at day 21 associated with clinical improvement. In conclusion, D-Dimers has a known strong negative predictive value, Increased values could be in some ambulatory situation of suspected PE and treatment decision marker and D- Dimers kinetic associated with clinical improvements could confirm afterwards the decision taken.

P-0328

Guillain Barre' Syndrome in a patient with hepatopathy

Silvia Sánchez Casco, Pedro Alejandro Gonzales Flores

Catalan Health Institute, Barcelona. Spain

INTRODUCTION

Guillain-Barré' Syndrome is an autoimmune disorder without a clear trigger that affects nerve endings causing demyelination. It often occurs after one minor infection. Symptoms can be very serious. Existing treatments do not cure but they improve symptomatology, treat complications and accelerate recovery.

DESCRIPTION OF THE CASE

46 year old patient with pathological history of moderate alcoholism and smoking, since a month ago launches a distal paresthesias in the 4 extremities with progressive hypoesthesia of proximal to distal home accompanied by alteration of the march. Physical exploration: distal dominance with areflexia tetraparesis. Vibrating and painful hypoesthesia of distal dominance in all four extremities. Three traverses hepatomegaly. Rest of exploration without alterations Complementary explorations: analytical hemoglobin 9.2. Hematocrit 26.8%. VCM 93. Platelets 133. 53% quick index (v.n: 70-130). 1.48 (0.85-1.15) prothrombin time GGT 21. GGT 159. Direct coombs test is positive. Iron 24 (vn 50-170). Ferritin 23(vn 10-120). Cerebrospinal fluid (CSF): total protein 47 (vn: 15-45). Microbiology and stain Gram negative (CSF). Electrocardiogram: sinus, 80x', no alterations in repolarization rate. Electromyogram: Discrete alteration in the form of overall increase of normal F-wave with a peripheral sensory study and motor latencies. Liver Ultrasound: chronic liver disease without occupying lesions of space or ascites. Fibrogastroscopy: erosive antritis and esophageal varicos veins grade II. The patient was diagnosed by progressive clinic, physical and neuropsychological examination and discret protetinas increase in CSF of Guillain Barre ', while compatible with chronic liver disease findings not previously studied in patient with chronic enolico habit were detected during her hospitalization.

ACTION

Started treatment with immunoglobulins 20 g for 5 days which was well tolerated and rehabilitation treatment with good response, obtaining an independent ambulation. In turn iron ev was administrated and then oral and a treatment with beta-blockers was begun recommending absolute abstention from alcohol

When prevention is not enough

Joana Relva, Rui Caramelo, Manuel Sousa
Canelas Family Health Unit, Canelas, Portugal

Context:

Pulmonary embolism is a blockage in the pulmonary arterial territory. In most cases, pulmonary embolism is caused by blood clots that travel to the lungs from the legs or, rarely, other parts of the body (deep vein thrombosis). Although anyone can develop deep vein thrombosis and pulmonary embolism, factors such as immobility, cancer and surgery increase the risk. Pulmonary embolism can be life threatening, but prompt treatment can greatly reduce the risk of death. Taking measures to prevent blood clots will help protect against pulmonary embolism.

Case description:

DFC, 56 years, male, without pathological relevant past medical history. In December 23th 2014 (Day 1), he fell and fractured his left leg and had to be immobilized with a splint. For prevention of thromboembolism, was medicated with Low-Molecular-Weight Heparin (LMWH). Later, in December 31st (Day 8), he complained of malaise with vomiting and sudoresis. On Day 13, he started having posterior right thoracic pain with anterior irradiation, which worsened with deep inspiration, associated with dyspnea. On Day 17, while waiting for an orthopedic consultation, he felt intense chest pain, dyspnea, diaphoresis and fainting. In the ER, he was diagnosed with acute massive pulmonary embolism.

DISCUSSION:

It is well known that immobilization leads to local venous stasis by accumulation of clotting factors and fibrin, resulting in thrombus formation. The risk of pulmonary embolism increases with prolonged bed rest or immobilization of a limb with a cast. The use of LMWH is one of the ways to prevent pulmonary embolism but, as shown before, may not be enough. The recognition of signs and symptoms of thromboembolism is important to a prompt identification and treatment, even if primary prevention had taken place.

Keywords: prevention; immobilization; pulmonary embolism;

Background & AIM: Community-acquired pneumonia (CAP) is a major cause of morbidity and mortality in adults even in developed countries. The annual incidence of CAP in adults in Europe is between 1.07 and 1.2 per 1,000 person/year. The aim of this study is to assess the incidence of CAP in primary care adults in Spain.

METHOD: Retrospective observational study in adults (>18 years-old) with CAP diagnosed and attended at primary care in Spain between 2009-2013, using the National Surveillance System of Primary Care Data (BiFAP).

RESULTS: 28.413 patient records were retrieved and analysed. Global incidence of CAP in adults was estimated at 4.63 per 1000 persons/year. CAP incidence increased progressively with age, ranging from a 1.98 at 18-20 years of age to 23.74 in patients above 90 years of age. According to gender, global CAP incidence was slightly higher in males (5.04) than females (4.26): CAP incidence from 18 to 65 years-old up was comparable between males (range: 2.18-5.75) and females (range: 1.47-5.21), whereas from 65 years of age, CAP incidence was noticeable higher in males (range: 7.06-36.93) than in females (range: 5.43-19.62).

CONCLUSIONS: Annual incidence of adult CAP in primary care in Spain is higher than that reported for Europe. CAP incidence is comparable between males and females up to 65 years of age, but clearly increases in males from that age.

P-0331

Acute abdominal pain: never say never!

Nelson Gentile, Camilla Bersani

Department of Primary Care, Bologna, Italy

BACKGROUND and AIM: Acute abdominal pain is a changeling complaint, frequently benign, but can herald serious acute pathologies (table1). Due to the difficulty to identify which patient could be safely treated symptomatically and which should require further investigation or specialist referral, the authors'd like to focus on accurate diagnostic and therapeutic pathway.

METHODS: E.L.Y., 26 years old, from Morocco, abdominal pain unlocated since the evening before after eating a pizza. He's living in Italy for almost two years and first time visiting his doctor. Past history, reported unlikely due to linguistic barrier, not significant for important previous pathologies or allergies. Physical examination: body temperature 35,8° C, mild sweating, blood pressure 110/70 mmHg, 74 beats/minute, pain score 4/10, soft defense reaction in epigastrium after deep palpation, abdominal bruits presents, vigorous muscles, SaO2 99%. The General Practitioner prescribes anti-acid agents, paracetamol and antiemetic drugs and fixes an appointment for next week. During the day the man stay worse, so decides to go to the hospital. In the emergency room the patient undergoes abdominal ultrasound which underlines abdominal effusion, immediately after tc highlights free air in peritoneum. Neutrophilic leukocytosis is detected. After a few hours the young male is operated for a perforated gastric ulcer.

DISCUSSION: When a patient refers abdominal pain first medical evaluation should include accurate history and targeted physical examination to decide how to act. When doctor is even minimally suspicious for "surgical abdomen" (both peritonitis and obstruction) laboratory measurements, radiography and ultrasound should be required. Furthermore the patient could undergo TC and laparoscopy (image1). This sequence gives the possibility for a reasonable choice on management.

CONCLUSION: Clinical acumen could be misleading in acute abdominal pain. Following carefully a logic and evidence-based diagnostic and therapeutic step-by-step lane is the way to positively impact short and long term patient prognosis.

Keywords: acute abdominal pain, accurate evaluation, "surgical abdomen", diagnostical and therapeutic pathway

Acute pulmonary edema display case

Tamara Draskovic¹, Xenia Pantic¹, Anelya Roshu²

¹medical centre zitishte, emergency unit

²medical centre zitishte, general practice

CAPTION:

Acute pulmonary edema is one of the most urgent conditions in medicine. The clinical picture is dominated by a sudden dyspnea caused severe degree, audibly gurgling in his chest, pallor, cold, sweaty skin, weakness, adynamia and foamy sputum, The auscultation can hear medium or large damp crackles diffuse the lungs.

PURPOSE:

Is to describe the diagnosis and adequate care for patients with acute pulmonary edema with respect good clinical practice in primary health care.

DESCRIPTION CASES:

A man, aged 74, was admitted to the clinic around midnight due to suffocation. Home difficulties before two o'clock in the form of chest pain and shoulders.

Status: conscious, oriented, communicative, pale, drenched, cold sweat, visible peripheral cyanosis of the lips and earlobes, without fever, dyspnoea, orthopnea, use auxiliary respiratory muscles with retraction above collarbone cavity.

Vital parameters: TA 240 /140 mmHg SpO₂ 81 %, fr: 105 / min. sug.: 14.2 mmol /l tt 36.7 °C No respiration: 25/min auscultatory FINDINGS: cardiac action rhythmic, quieter tones, damp diffuse crackles on both sides of the lung.

ECG: rhythm sin HR 105/min, the initial ST elevation in V1, V2, Q u d3, AVF, QS V2, V5 signs of LVH

Therapy: open two venous lines, we applied two amp. furosemide lvi one amp. nyrmin ^{**}(1&2 + 1&2) IV, O₂ administered through a mask 5 l, transportation time from the beginning of the review to the hospital 20 min.

CONCLUSION:

Adequate and timely therapy at primary health care level leads to good patient response, improving health and a shorter hospital stay.

KEY WORDS: acute pulmonary edema, adequate therapy, the primary health care level.

P-0333

Soft tissue metastases as first clinical manifestation – Case Report

Sara Raquel Magalhães, Érica Viana Rocha

USF Alphamouro, Sintra, Portugal

Background: Soft-tissues metastases are uncommon and rarely reported. This diagnosis should be suspected in the presence of a cutaneous lesion of difficult resolution. They are identified in 1.3-4% of lung cancer patients.

Following lung cancer, kidney and colon carcinoma are the most associated with these invasive disease manifestations. This case report illustrates how severe illness can present itself as an apparently benign lesion, reminding us of the relevance of patient follow-up.

Case Presentation: A 78 years old Caucasian overweight male, ex-smoker of 100 smoking pack-year, with a history of hypertension, dyslipidemia, COPD presents to his GP referring painless skin lesion with 15 days of evolution. Physical examination revealed a tender mass, with inflammatory signs suggesting an inflamed sebaceous cyst or lipoma, for which he was treated with antibiotic therapy. One week later the patient returned with the persistent lesion, which had become ulcerated, draining pus and exudate. Further investigation with ultrasonography revealed a lesion suggestive of metastatic dissemination. Blood work revealed iron-deficiency anemia and elevated inflammatory protein levels. The lung CT scan divulged a solitary nodule compatible with primary lung cancer. The patient was promptly sent to oncology for follow-up.

CONCLUSION: Soft tissues metastases, given their low incidence and nonspecific presentation can easily be misdiagnosed at first examination. This clinical case demonstrates the value of the available and accessible

continuous care provided by GPs. The close follow-up of patients' complains by an attending physician leads to a more timely and correct diagnose.

Disclosure: No conflict of interest declared

Síndrome de Miller-Fisher

Enrique Almenar Cubells, Edelmira Moreno Perez, Enriqueta Hernandez Hernandez, Alfredo Quiles Raga, Diana Diaz Gil, Perez Quintana Oscar
Centro de Salud de Benifaio, valencia, Spain

Introductory

The Miller-Fisher syndrome is an atypical variant of Guillem Barre syndrome.

The establishment of the table usually acute in hours or days It is characterized clinically by ataxia, areflexia and ophthalmoplegia. In 72% of cases there is a previous infectious respiratory and enteric second place expense.

CASE:

Patient begins with of congestion and sneezing accompanied by mild fever the next day, headache and cold sores so went to the family doctor that pattern paracetamol and ciprofloxacin after making these the next day

dysarthria ataxia, dysphagia double vision, numbness in hands and feet

Login with suspected Guillem Barre Syndrome

TAC within normal

EMG mildly affected the bilateral median nerve within the normal rest

Normal Evoked Potentials

MRI within normal limits but there are areas of white matter ischemia

Analytical dissociation CSF albumin-cytology and increased anti Ac GQ1b

Diagnosis of Miller-Fisher syndrome

Action Strategy:

The patient evolves favorably to treatment with immunoglobulin and with oropharyngeal and respiratory symptomatic improvement, stable ride and rehabilitation therapy and speech therapy

It must be taken into account from the Primary Care complications of viral and digestive processes which sometimes can give clinical complications

Keywords: Miller Fisher syndrome, Guillem Barre syndrome, ataxia, respiratory infection

A case of choleduocholithiasis and weight loss

Adela Ioana Uta¹, Claudia Elena Uta¹, Lia Anguelova Valentinova²

¹Aragon Service of Health, Sector II, Zaragoza, Spain

²National Institute of Endocrinology CI Parhon, Bucharest, Rumania

INTRODUCTION: Disturbances in lipid metabolism, which occur during weight loss lead to formation of gallstones. The aim of this work is to report the case of a woman with a 30 kg weight loss and acute cholecystitis.

Case presentation: A 26-years old female presented in the emergency department with right upper abdominal pain, accompanied by nausea and vomiting for 6 days. That same morning she presented jaundice and clay colored stools. She denied fever. No history of any illness or drug use. The only significant past history is of 30 kg weight loss in the last 12 month with a low-fat, low carb diet (1000Kcal per day mostly salads, fish and lean meat) and exercise.

Physical exam revealed a soft but tender upper abdomen. Full blood count with white cell was normal, inflammatory markers as well, but liver enzymes were mildly elevated.

The ultrasound showed gallbladder with multiple calculi and common duct dilatation (11 mm).

The abdominal CT scan, performed one week later, revealed signs of cholelithiasis, with no choledocholithiasis.

A magnetic resonance cholangiopancreatography was also performed and it confirmed the diagnosis of cholelithiasis.

The patient underwent surgery, with full recovery.

CONCLUSIONS:

Two most commonly suggested mechanisms for gallstone formation are supersaturation of bile with cholesterol, as a result of reduced biliary bile, salt secretion and enhanced mobilization of cholesterol and the insufficient gallbladder emptying due to impaired motility.

Common way of achieving insufficient gallbladder emptying is a low fat, low fibre diet without the preventive use of ursodeoxycholic acid.

It would be very sensible for the general practitioner to supervise the patients that are losing weight through regular blood checks and abdominal ultrasound as a reference before commencing a diet. And also it would be advisable to be done in joint team with an endocrinologist or a dietician.

P-0336

A Different Case of Fever - A Case Report of Chikungunya Fever

Céline Raposo Gama, Sara Margarida Cunha, Sophie Amandine Sousa
USF Oceanos, ULS Matosinhos, Porto, Portugal

BACKGROUND & AIM:

With the increasing popularity of international travel to exotic locations, family physicians are encountering more febrile patients who have recently returned from a tropical country. These patients' assessment is often impaired by the clinician's lack of familiarity with the infections that they may have contracted while travelling to these locations. The aim of this case report is to raise awareness for the importance of conducting a systematic approach in the evaluation of fever in the returned traveler.

METHODS: A case report based on patient's interviews and electronic clinical records. A research was conducted for clinical review.

RESULTS: Female patient, 31 years old, with a personal history of hypothyroidism and allergic rhinitis. She's been living in Angola for the past year, for work-related purposes. A few days after she returns to Portugal, she made an appointment with her family physician due to the onset of fever, poliarticular pain, generalized muscle pain and headache. The only finding on physical examination was the presence of submandibular lymphadenopathies, so she was treated with supportive care. After four days she returns to her family physician. She had no fever, but still complained with poliarticular pain, and had developed a generalized rash. The blood work showed leukocytosis, thrombocytosis and elevated C-reactive protein levels. The patient was then referred to Secondary Health Care, Chikungunya and Dengue's serologies were asked, and the diagnosis of Chikungunya Fever was confirmed.

CONCLUSION: Chikungunya is a virus endemic to West Africa that causes acute febrile poliarticular pain and arthritis. Although in most cases a fever is caused by a common infectious disease, like urinary or upper respiratory tract infections, fever in returned travelers should always raise the suspicion of a tropical infection. Family physicians play an important role in the preventive care that must be taken before travelling to exotic locations.

Keywords: Chikungunya fever, Travel, Arthralgia, Exanthema

Medical appointment

Date Local

21/04/14 Primary Health Care

Fever (39° C), polyarthralgia (wrists, knees and ankles), generalized myalgias and headache, since yesterday. Without any respiratory, urinary or gastrointestinal symptoms. She has returned from Angola 5 days ago.

Physical examination: painless submandibular lymphadenopathies; ears, oropharynx, heart and lungs auscultation: normal

Treatment: supportive care + ibuprofen 600 mg, acetaminophen 1000 mg

24/04/14 Primary Health Care

Generalized pruritic rash. The fever has passed, but she still complains with polyarthralgia.

Physical examination: maculopapular rash (trunk and extremities); heart and lungs auscultation: normal

Treatment: bilastine 20 mg

07/05/14 Primary Health Care

Polyarthralgia (knees and ankles)

Physical examination: pain with joint mobilization and minor edema

Complete blood count and C reactive protein levels à leukocytosis, thrombocytosis and elevated C reactive protein levels

Treatment: ibuprofen 600 mg. The patient was referred to Secondary Health Care

15/05/14 Secondary Health Care

Chikungunya and Dengue's serologies were asked, and the diagnosis of Chikungunya Fever was confirmed

Evaluation of unfocal fever in the returned traveler

How to evaluate unfocal fever in the returned traveler

♣ Medical history

♣ Pre-travel history (immunization, chemoprophylaxis)

♣ Travel history (travel itinerary, purpose of travel, description of the accommodations, sexual history, list of exposures and risks factors)

♣ Physical examination (vital signs, skin, heart and lungs, abdomen, lymph nodes and neurological system)

♣ Always consider common causes first (upper respiratory and urinary tract)

♣ Exclude non-travel causes (the fever may have nothing to do with the trip)

♣ Incubation period <21 days (malaria, typhoid fever, dengue fever or rickettsial diseases) vs >21 days (malaria, hepatitis A or tuberculosis)

♣ Consult with an infectious diseases specialist if the patient is particularly ill, with altered mental status, or when the diagnosis isn't clear

P-0337

Ecchymosis in Young Women: Gardner Diamond Syndrome

Fatma Selek Demirel¹, Ilkay Özer², Yasemin Alagöz¹, Fatma Gökşin Cihan³

¹Konya Training and Research Hospital FM Clinic

²Konya Training and Research Hospital Dermatology Clinic

³Necmettin Erbakan University Meram Medical Faculty FM Department

Background and AIM: Gardner Diamond Syndrome (GDS) is a rare disease distinguished with painful ecchymosis, skin and mucosal bleeding throughout different parts of the body. Skin lesions and bleeding appear in most cases following an emotional stress, are seldomly preceded by small traumas and can recur. Hemostatic tests are generally normal. It is mostly observed in irate young women. In most patients a correlation between tissue lesions and psychiatric problems was detected and it was suggested to name the syndrome as “psychogenic purpura”. Ecchymosis, generally appears as erythema, edema, fever and pain respectively. It is developed in 2-6 hours (maximum 24 hours) following tingling, burning and stinging. This period lasts about 24 hours and inflammation transforms to ecchymosis while the swelling shrinks.

CASE: 24 years old woman patient applied to the dermatology clinic due to bruises on her body. Her history indicated that she had upper respiratory tract infection 2 weeks ago and in the following week ecchymosis, reaching up to size of 3 cm, with irregular borders were developed. There was not any other concomitant pathology in physical examination except ecchymosis. She committed a suicide previously. She had been followed at psychiatry clinic for anxiety disorder. There was no medication history. In blood tests her Hb: 10,6gr/dl, PLT: 354000 K/uL, WBC: 8750 K/uL. Bleeding tests were in normal limits.

CONCLUSIONS: In this syndrome, bleedings in different regions such as nose, ear, eye, and digestive system can accompany tissue lesions. Intra-dermal tissue test can be diagnostic. Antihistaminic, antimalarial, immunosuppressive drugs, steroids, antibiotics, estrogens, and vitamin C were tried but the best treatment is the psychotherapy and psychotropic medication. The patients applying with recurring spontaneous and painful ecchymosis and with normal bleeding and coagulation test results, should be referred to psychiatrists.

Keywords: Gardner Diamond Syndrome, ecchymosis, women

Ecchymosis

P-0338**Vitamin B12 Deficiency in Primary Care: A Case Presented with Pancytopenia**

Yeliz Özendi, Çiğdem Apaydın Kaya, Sevim Aksoy Kartçı, Saliha Şahin, Kübranur Demir
Department of Family Medicine, Marmara University, Istanbul, Turkey

Background and AIM: Vitamin B12 deficiency which is seen commonly in Primary Care could be presented with hemotological and neurological symptoms. We would like to remind that B12 deficiency can be detected with pancytopenia in primary care.

CASE: A 64 year-old male consulted his Family Physician with diarrhea without blood or mucus. He has no disease and medication. At the doctor visit, he had malaise for 3 months with no weight-loss, fever or night-sweat. At laboratory workup hemoglobin was 5.4. Then, he was referred to an emergency care center. At the emergency room Hb:4.8, Htc:13.9, MCV:105, WBC:2800, Plt:62000. After taking blood specimen for blood smear, he was given 1U erythrocyte transfusion and referred to Hematology department. On his physical examination: patient was conscious, vital signs were stable, skin was pale no petechia or purpura, no active bleeding, no hepatosplenomegaly and other system examination was normal. On blood smear there's no blast, normochromic and macrocytic erythrocytes, rarely teardrop cells, PNLs with 5 lobes, 8-9 platelets in every area; LDH:6414, Vit B12:<50 pg/mL, Haptoglobin:<0.0583, reticulocyte:2.8. T.bil:1.61, D.bil:0.24, Fe:104, TFBC:306, Ferritin:384, Folic acide:6.46. Hepatitis serology and HIV antigen negative, Direct-Indirect Coombs negative. Patient was diagnosed as Vitamin B12 deficiency and given 1000 mcg/day cyanocobalamine IM. After 1 week later laboratory findings were Hb:6.9, MCV:102, WBC:3300, Plt:62000, LDH:2872. He benefited from vitamin B12 replacement. To find out the etiology, gastroscopy was performed and erosive antral gastritis was detected. At follow-up with parenteral vitamin B12 treatment, pancytopenia and his symptoms were regressed.

Conclusion and RESULT: Vitamin B12 deficiency could be detected and treated in Primary Care, but this patient had Hb value of 5.4 and pancytopenia that required to refer a tertiary care center for further investigation. Our case has the importance for showing Vitamin B12 deficiency firstly presented with pancytopenia rather than megaloblastic anemia.

Keywords: Vitamin B12 Deficiency, Pancytopenia, Primary Care

P-0339**Case Report: Using of Antibiotic is cause of false-negative rapid antigen test**

Funda Ekimci Deniz, Tuğba Beyazçiçek, Ayşe Semra Demir Akça, Nejat Demircan
Department of Family Medicine, Faculty of Medicine, Bulent Ecevit University, Zonguldak, Turkey

Acute tonsillopharyngitis is one of the most common disorders encountered by primary care physicians. Various classifications, clinical diagnostic procedures and laboratory tests are used in order to make the distinction between bacterial and viral. Rapid antigen tests are commonly used for this purpose. This case is presented for reminding that antibiotic use affects the results of rapid antigen testing and highlight the need to evaluate antibiotic use based on the situation. A week ago, because of high fever, acute tonsillopharyngitis is diagnosed in a seven-year-old male patient who was admitted with complaints of cervical lymphadenopathy on off-center and amoxicillin clavulanate treatment was started. On the third day of treatment, his fever reduced but swelling in the neck developed. Family again admitted to the same doctor and they were said it was due to acute tonsillopharyngitis lymphadenopathy and the patient, who was advised to continue antibiotic treatment, is referred when swelling in the neck didn't persist. Rapid antigen test of the throat swabs taken from patient was negative. Rapid antigen tests give us information in short time periods as 10 minutes in diagnosis of acute tonsillopharyngitis. Patient's history should be listened by considering frequent use of antibiotics without the supervision of physicians and it should be known that negative result doesn't provide us any idea in situation of antibiotics use in the last one week. In such cases where the test is negative we must not forget that we need to take advantage of other clinical scoring.

Sciatica or Pseudosciatica? A Case Report

Catarina Viegas Dias, Catarina Mariano Leal
USF Dafundo, ACES Lisboa Ocidental e Oeiras, Oeiras, Portugal

Background & Aim

Low-back pain (LBP) is one of the most frequent complaints in the Primary Care setting. Piriformis syndrome is an underdiagnosed cause of LBP, that can present with irradiating pain, mimicking radiculopathy. We present a case report that highlights the importance of early identification of symptoms and signs that are unique to piriformis syndrome, enabling appropriate treatment in a timely manner.

Case report

We report a case of a 47 year-old female, currently unemployed, part of a monoparental family. The patient presented as active health problems an ovarian cystadenoma and Hashimoto's thyroiditis. She attended to an urgent appointment complaining of right gluteal pain, irradiating to the hamstring, that worsened with prolonged sitting. Physical examination revealed right buttock tenderness, limited medial rotation of the ipsilateral lower extremity, positive piriformis sign and positive Lasègue sign. Piriformis Syndrome was considered the most probable diagnostic hypothesis, and analgesic therapy was prescribed. The patient returned to a routine appointment, 2 weeks later, still complaining of persistent gluteal pain, partially resistant to naproxen. The physician decided to optimize the treatment plan, combining analgesia with stretching exercises of the piriformis muscle, and referred the patient to a Physiotherapy clinic. After 15 sessions of Physiotherapy treatments the patient improved significantly and was able to resume physical activity.

Conclusions

Piriformis syndrome is a complex condition that should be considered in the differential diagnosis of subacute or chronic hip and low back pain. This patient presented with irradiating pain and revealed a positive Lasègue sign, which could mislead the clinician. However, a thorough and directed clinical examination, as well as a high clinical suspicion, led to the diagnosis of Piriformis Syndrome.

Background & AIM: Community-acquired pneumonia (CAP) is a major cause of morbidity and mortality in adults even in developed countries. The emergence of new pathogens and the variation of resistance over time require studies that reveal the actual antibiotic therapy approach in CAP. The aim of this study is to assess the antibiotic use in adults with CAP at primary care in Spain.

METHOD: Retrospective observational study in adults (>18 years-old) with CAP diagnosed and attended at primary care in Spain between 2009-2013, using the National Surveillance System of Primary Care Data (BiFAP).

RESULTS: 28.413 patient records were retrieved and analysed. The distribution of the main antibiotics used was: amoxicillin-clavulanate (36.0%), levofloxacin (28.5%), moxifloxacin (18.5%), azithromycin (15.0%) and amoxicillin (14.5%). Combined therapy was used in 37.3%, mainly with the association amoxicillin-clavulanate + levofloxacin (10.6%) and in 55-70 years age group (44,4%). Amoxicillin-clavulanate was the first choice of treatment independent of age or sex, followed by levofloxacin and moxifloxacin in patients 55 years old or over, while amoxicillin and levofloxacin was used in patients under 25 years. Distribution according to age and underlying disease: a) <65 year old without any chronic conditions: amoxicillin-clavulanate (37.2%), levofloxacin (25.2%); b) >65 years old or with the presence of chronic conditions: amoxicillin-clavulanate (32.1%), levofloxacin (30.2%).

CONCLUSIONS: The antibiotic election adequacy in primary care adults with CAP is low according to national and international guidelines. Amoxicillin-clavulanate is the main antibiotic prescribed. Second choice treatment options are quinolones in older patients and amoxicillin for the younger.

Orally or intramuscularly?

María Del Socorro Fernández Guillén¹, Carmen Celada Roldán², Alexandru Claudiu Coman³, Madalina Daniela Graure³, Esther Cañada Cámara⁴

¹Mar Menor health center, Cartagena, Spain

²Los Dolores health center, Cartagena, Spain

³Cartagena casco health center, Cartagena, Spain

⁴San Anton health center, Cartagena, Spain

• Background and aim: A 45 year-old woman is attended by her general practitioner for fever, polyarticular joint pain and malaise in the last week. She took Paracetamol and Anti-inflammatories without any improvement. No important medical history.

Clinical examination: Blood pressure: 90/50 mmHg, Fever (39.5°C), pale skin, malaise, joint pain with the passive and active mobilization.

She is remitted to the Emergency Room for investigation.

• Method: Blood analysis: Urea 116 mg/dl, Creatinine 2.36, Na 125 mmol/l, Ca 6.6 mg/dl, LDH 517 UI/l, CK245 UI/L, PCR 41 mg/dl, Hb 9.3 g/dl, Leucocytes 18.81 x10e9/L, Neutrophils 18.16 x10e9/L, Platelets 105 x10e9/L

Thorax X-Ray, Abdominal Echography: Normal

Blood and urine culture: Negative

Left gluteus echography: a 5x3cm abscess with echogenic content

Collection culture: S. Aureus

The patient is admitted in the Intensive care unit, where an antibiotic and supportive treatment is initiated, with the improvement of the patient's situation.

• Results: Diagnosis: Sepsis due to gluteal abscess, with acute renal failure

Differential diagnosis: Infections, any type of shock, acute suprarenal failure

• Conclusions: Sepsis is a systemic inflammatory response syndrome caused by an infection, which presents various symptoms. The treatment must be supportive, to prevent organ failure and to treat the primal infection. It has a very high mortality, a quarter of the patients with severe sepsis and half of the patients with septic shock pass away in the first 30 days. To ensure a quick diagnosis and treatment it is mandatory to do a good medical history and a thorough clinical examination.

Keywords: Sepsis, intramuscular injection, polyarthralgia

Gluteus echography

Collection with echogenic content. Measures 5x3 xm. The wall does not show doppler flow. These findings are compatible with abscess.

Antibiotic prescribing in primary care for upper respiratory tract infections

Attila Altiner¹, Martin Duerden², Roman Kozlov³, Ashok Mahashur⁴, Laura Noonan⁵, Aurelio Sessa⁶, Adrian Shephard⁷

¹Rostock University Medical Center, Rostock, Germany

²Bangor University, Bangor, UK

³Smolensk State Medical Academy, Russia

⁴University of Mumbai and Banaras Hindu University, Mumbai, India

⁵Respiratory Tract Treatment Forum, Ireland

⁶Società Italiana di Medicina Generale, Lombardy, Italy

⁷Reckitt Benckiser PLC, Slough, UK

BACKGROUND AND AIM:

Antimicrobial resistance (AMR), a WHO-recognized threat to global health, is perpetuated by non-rational antibiotic prescribing, particularly upper respiratory tract infections (URTIs). Most are self-limiting; for 60-90%, antibiotics provide neither resolution of the condition nor symptomatic relief. Greater emphasis on educational resources and non antibiotics symptomatic therapies is needed.

METHODS:

In 2014, Reckitt Benckiser conducted an online multinational consumer study (total 17,302 interviews ~530 per country, 33 countries) to investigate the patient pathway for minor ailments in the preceding 12 months. We report URTI results, including specifics for UK, Italy, India, Russia, Germany and Ireland..

RESULTS:

Overall, 65% of subjects (11,261) reported a URTI symptom in the previous 12 months (56% UK-71% India), multiple URTI symptoms were often reported. 35% (6135) contacted a healthcare professional (HCP) for URTI symptoms (16% UK-49% India) with physicians (31%; 5303) the preferred HCP for consultation (12% UK-45% India).

Of subjects contacting a physician for URTI, 59% (3140) were recommended a product (UK 44%-Italy 71%), of which 85% then obtained the recommended product. 49% (2612) were prescribed a product (Italy 33%-Russia 55%), with 81% then having the prescription dispensed.

20% (1047) of physician consultations resulted in antibiotic recommendation that was then obtained (9% UK-27% India); 18% (969) resulted in an antibiotic prescription that was then filled (6% Italy-29% Ireland).

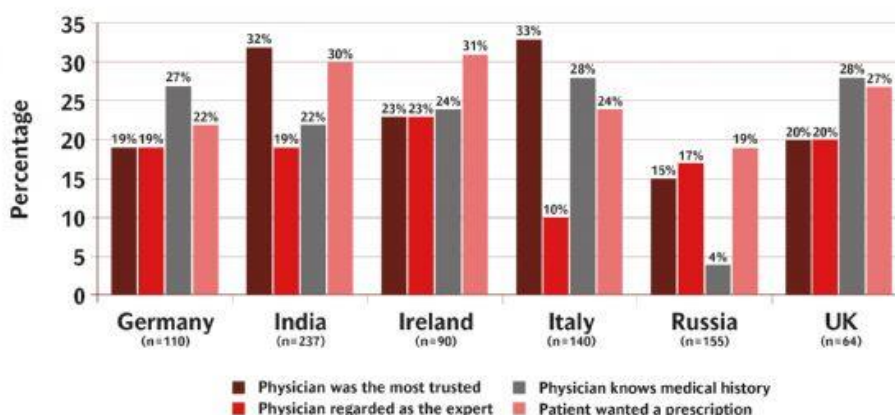

Primary reasons for HCP consultation were trust, familiarity and prescription need. Easy product access and lack of concern were the main reasons for no HCP contact.

CONCLUSIONS:

Results confirm physicians' pivotal role in providing advice and treatments to URTI patients because they are seen as experts. Antibiotics continue to be used for URTIs, mostly inappropriately. The Global Respiratory Infection Partnership (GRIP) has developed educational materials based on what we call a 1,2,3 approach to facilitate physician-patient discussion on URTI conditions, antibiotics and appropriate symptomatic self-management.

Keywords: Antibiotics, Respiratory tract infections, Primary healthcare

Figure 4: Global Respiratory Infection Partnership 5P Framework

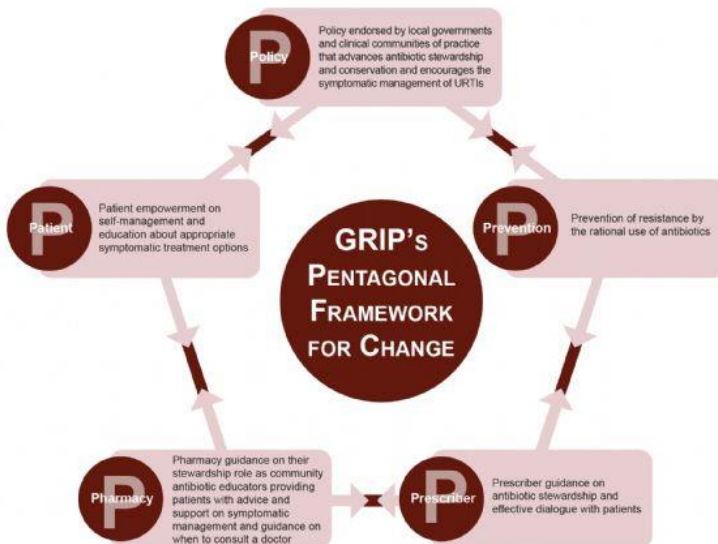

Figure 5: GRIP's 1,2,3 approach for HCPs

Box 1: Changing behaviour in practice - Ireland, Laura Noonan

- In Ireland the majority of antibiotics are prescribed in primary care. As shown in this new study, Ireland had the highest number of URTI patients reporting they had received and filled an antibiotic prescription (29%) of the six countries analysed. Yet, implementation of a patient-centred, enhanced consultation could reduce this figure.
- A previous patient-intervention study in a single clinical practice in Ireland assessed patient knowledge and attitudes towards antibiotic use for URTIs. Some 26.6% of patients reported feeling the doctor did not understand the severity of their symptoms when they did not receive an antibiotic prescription, with 30% consulted with the express purpose of obtaining a prescription for an antibiotic. The majority consulted for symptom relief (43.3%), with others seeking diagnostic clarification (13.3%) or to get certificate for absence from work (13.3%).
- A patient information sheet was used during consultations in the intervention group to provide them with knowledge on the appropriate use of antibiotics and the side effects and potential risks of antibiotics. The control group had a standard consultation.
- The intervention reduced immediate antibiotic prescribing from 47.5% to 13.3% and delayed prescription rates increased from 15% to 43.3%. Inappropriate prescribing was reduced from 10% to 3.7%.
- In addition, consultation time was reduced from 11 minutes to 10 minutes and fewer patients re-consulted.
- The study illustrates the benefit of having an enhanced dialogue with patients. Local, up-to-date evidence based guidelines should also be available for GPs to recognise the benefit within their community.

Box 2: Changing behaviour in practice - Italy, Aurelio Sessa

- As shown in this new study, Italy had the lowest number of GPs prescribing antibiotics for an URTI (6%) of the six countries analysed. It should be noted, however, that under-the-counter antibiotic sales occur in Italy, which may account for the low figure here, in addition to possible confusion in patient self-reporting in the study.
- A previous study considered the impact of the GRIP antibiotic prescribing toolkit on prescribing rates in clinical practice. This patient-intervention study assessed use of the toolkit among consecutive patients presenting with sore throat from September 2013-November 2013, inclusive.
- In total 165 adults were included, with an even gender split and median age of 39 years. On average, sufferers had 2.9 days with a sore throat prior to consultation, with median severity of 2.96 (maximum score = 5).
- Antibiotics were prescribed in 41.2% of cases, with a marked reduction in antibiotic prescribing where the GRIP toolkit materials were used in the patient consultation: 29% vs. 44%.

Box 3: Changing behaviour in practice - GRIP support

GRIP provides a range of support materials that can be downloaded from its website:
www.grip-initiative.org

P-0344

Glomus Tumor: an unusual cause of finger pain

Ana Raquel Cunha¹, Sandrina Costa¹, Daniela Pinto², Daniela Pedrosa³

¹USF Bracara Augusta, Braga, Portugal

²USF MaxiSaúde, Braga, Portugal

³USF Torrão, Lousada, Portugal

Background

Glomus tumor is a rare benign neoplasm, arising from the neuromyoarterial smooth muscle receptors that are sensitive to temperature and regulators of microvascular circulation. It is more common in young adults and in females, accounting for 1-5% of neoplasms of the soft tissues of the hand. Usually presents as a solitary lesion, subungueal or in the fingertips, but may be found in other locations. Diagnosis is clinical, presenting as an acute pain in the fingertip triggered by palpation and cold sensitivity. X-rays, ultrasound or MRI can help, but the definitive diagnose is determined by histopathology. Differential diagnosis includes melanoma, neuroma, angioma, melanocytic nevi and arteriovenous malformations. Surgical excision is the only known definitive treatment.

Case Report

REMD, male, 40 years old, clerk, with no relevant past medical history. He belongs to a nuclear family, with a moderate dysfunction of familial APGAR and within class VI of Duvall life cycle. He attended several times his health unit in December 2014 due to acute pain in the 4th fingertip of the left hand, triggered by touch and cold, complicating his job. On inspection he had a reddish area of 1 mm diameter on the ulnar side of the 4th finger. X-ray and ultrasound were normal. He was then referred to Dermatology consultation, and subsequently to Orthopaedic consultation. Due to high clinical suspicion, surgical excision was performed, whose histological exam revealed a Glomus tumor. Patient symptoms were completely reversed after surgery.

Discussion

Although Glomus tumor is a rare benign entity, it can be quite disturbing due to pain triggered by the slightest touch or hypersensitivity to cold, and therefore it can interfere with the patients daily life activities. Family physician should be aware of this condition, in order to provide optimization in diagnosis and early treatment, maintaining quality of patients health.

Keywords: glomus tumor, fingerpain, cold sensitivity

³Department of Hematology, Medical Faculty, Karabuk University, Karabuk, Turkey

⁴Department of Physical Examination and Rehabilitation, KBU Karabuk Education and Research Hospital, Karabuk, Turkey

⁵Department of Chest Disease, Medical Faculty, Karabuk University, Karabuk, Turkey

⁶Department of Cardiology, Medical Faculty, Karabuk University, Karabuk, Turkey

Today thromboembolism (TE) is one of the most important mortality and morbidity cause. For TE, in high risk conditions combined therapy (CT) is preferred considering that these drugs are not sufficiently protective solely. When CT is applied, increased bleeding as a side effect is observed. In this report, CT's side effects are discussed in the light of a case who applied to hospital with broad skin rash due to usage of clopidogrel and warfarin combination.

CASE: A male patient age of 65 is applied to clinic of family medicine with broad skin rash on proximal extremity areas. History of warfarin and clopidogrel was exist as anticoagulant medication therapy due to coronary by-pass surgery with aorta and mitral valve replacement ten years ago. Rash was observed on interior thigh areas by physical examination (Fig. 1). There wasn't a finding except skin lesions in general examination. Prothrombin time was 25 sec. INR was 2.09, thrombocyte count was 186,000 μ L and bleeding time was increased (>15 sec.). In peripheral blood smear thrombocyte morphology and count was normal but aggregation of thrombocytes couldn't observed. Clopidogrel medication was ended considering mucocutaneous bleeding related to it. On 10th day of follow-up fading and on 3rd week total vanishment of petechies was observed.

DISCUSSION: In case of usage of both antiaggregant and anticoagulant drugs they may potentialize each other's effect. As a consequence, there may occur bleeding in varying locations and ratings. It is important of which medication's side effect is it when a complication arises due to usage of KT. Diagnosis and medical intervention must be immediately made due to risk of morbidity and mortality. Thus, family medicine specialized physicians must know well the effects and side effects of drugs in primary care health service with patients who use combined drug medication.

Malaria again! Fourth Time In a Healthcare Provider, Despite Prophylaxis

Yusuf Üstü¹, Salih Molahaliloğlu², Zeliha Tufan Koçak³, Basri Furkan Dağcıoğlu¹, Dilek Öztaş², Mehmet Uğurlu¹

¹Yıldırım Beyazıt University, Faculty of Medicine, Department of Family Medicine

²Yıldırım Beyazıt University, Faculty of Medicine, Department of Public Health

³Yıldırım Beyazıt University, Faculty of Medicine, Department of Infectious Diseases and Clinical Microbiology

Introduction

Malaria is a parasitic infectious disease which is common in tropical and subtropical regions, caused by different obligate intracellular Plasmodium species (*P. Vivax*, *P. Falciparum*, *P. malariae*, *P. ovale* and *P. knowlesi*). Since 2010 no new local malaria case has been reported in Turkey except relapsed or foreign cases. An imported malaria case has been presented here.

Case

A 47 years old man admitted to our outpatient clinic with complaints of fatigue going on for 1 week, occasional fever, headache, cold sweats, diarrhea and loss of appetite, which were mimicking viral diseases. In physical examination, he seemed exhausted, overall situation was good, orientated and cooperating. BP:120/70 mmHg, pulse:94/min and rhythmic, axillary fever:38,2 0C with normal systemic examination. It is learned that he was diagnosed for malaria 3 times after international travels and treated for it. He told that he had gone to Gambia 20 days ago and stayed there for a week. He had been taking Malaron for prophylaxis so that fever was not prominent and the clinical course was suppressed. In laboratory tests; Hgb: 12.6 g/dl (13,5-18), MCV: 79,6 fL, MCH: 26,2 pg (27-33), WBC: 12,97 K/uL (4-11), Neu: 9,87 K/uL (1,8-7,7), PLT:314K/ul (150-450), AST: 25 U/L (0-40), ALT: 31 U/l (0-41), LDH: 262 U/L (135-225), T. Bilirubin: 0,69 mg/dl (1,4) D. Bilirubin: 0,22 mg/dl (0,3). Hepatitis markers were in normal range.

In peripheral blood thick drop smear during fever, *P. falciparum* ring form was detected. Follow-up protocol was initiated for the patient after starting Artemether tablets.

Result

It is important to inform people about malaria and prevention, especially those who travel internationally. In symptoms like fatigue after travel and diarrhea, malaria should always kept in mind, even in cases with history of 3 times diagnosis for malaria before or still taking prophylaxis for it.

Gynecomastia in a young male

Ángel Hurtado De Mendoza Medina¹, Carmen María Jiménez Herrera², Ruth Muñoz Maya³, Elvira García Martín⁴

¹CS Doña Mercedes, Dos Hermanas. AGS Sevilla-Sur. Andalussia, Spain.

²CS Nuestra Señora de la Oliva, Alcalá de Guadaíra. AGS Sevilla-Sur, Andalussia, Spain

³CS Don Paulino García Donas, Alcalá de Guadaíra. AGS Sevilla-Sur, Andalussia, Spain.

⁴CS Virgen de Consolación, UGC Utrera Sur, Utrera. AGS Sevilla-Sur, Andalussia, Spain

Case Description: Male aged 29 years old comesto our office with bilateral gynecomastia, greater in his left breast of 6-8 months of evolution.

No drug allergies, not other medical history, no home treatment, non smoker, non drinker.

The general physical examination was normal except for bilateral gynecomastia without secretion from the nipple. No axillary alterations.

Complementary Tests:

- Blood general test: normal. There weren't any alterations in renal or hepatic test.

- Breast ultrasound: fibro-glandular tissue without nodules or calcifications found to suggest malignancy.

- Blood hormones: T4, prolactin and estradiol normal. Free testosterone 65 (normal: 89-280 pg / ml), FSH 2 IU / L (normal 1-10 IU / l), LH 2 IU / l (normal range (1-9 IU / l) with hypogonadism.

In his next consultation, we re-asked the patient about drug use (opiates, marijuana...). Finally, he tells us that

he's been using natural protein supplements and intramuscular injections with nandrolone and estanozolol when he does workout at the gym.

Diagnosis: Anabolic gynecomastia.

Treatment: We recommended the patient ceasing anabolic treatment. In more advanced cases we can use oral tamoxifen (in our patient was finally not necessary) or even surgical treatment.

Discussion:

- 1) The main causes of gynecomastia are: tumor (testicle, adrenal...), familial gynecomastia, drugs...
- 2) There are studies that show increased use of anabolic in young people who exercise and athletes, around 9.1% of males and 2.1% for women.
- 3) It is essential to perform a good medical history to avoid costly and unnecessary studies. The profile of this condition are young patients with athletic physical form.

Clinical impact of rapid point-of-care tests for acute sore throat

Jukka Vakkila¹, Minna Mäki², Maija Riitta Lindberg², Tuula Siljander², Anne Marie Ackermann², Jaana Raussi², Kristina Hotakainen¹

¹Mehiläinen Oy, Pohjoinen Hesperiankatu 17 C, 00260 Helsinki, Finland

²Orion Diagnostica Oy, P.O. Box 83, 02101 Espoo, Finland

Background

We investigated (1) clinicians' and (2) patients' expectations on rapid point-of-care (POC) tests for *Streptococcus pyogenes* (Strep A); (3) frequency of ordering Strep A and other tests for patients with pharyngitis; and (4) the performance of QuikRead go Strep A (Orion Diagnostica) against culture at two sites of a private healthcare service provider in Finland.

Methods

Questionnaires were used for gathering information from general practitioners, paediatricians and patients. QuikRead go Strep A tests were performed according to manufacturer's instructions and culture on selective blood media using one day incubation at 37°C.

Results

Altogether 55 clinicians responded. Forty-seven clinicians (85%) requested also blood tests, C-reactive protein and blood count most frequently. Twenty clinicians (36%) always order a Strep A test for a patient with symptoms. Fifty-two clinicians (95%) reported the Strep A test result to guide their decision on antibiotic prescription. Altogether 114 patients responded. Based on replies, 87% clinicians had considered a Strep A test necessary before treatment. Eight patients requested a Strep A test themselves. Twenty-eight physicians (25%) had prescribed the antibiotics before the test result.

130 samples were tested using QuikRead go Strep A and culture showing an overall agreement of 87% between these methods.

Conclusions

Even though only one third of responding clinicians always order a Strep A test to a patient with pharyngitis, the patient replies demonstrated that nearly 90% of treatment decisions were supported by Strep A test. Thus, the use of Strep A POC testing is highly driven by the clinicians. Only 7 % of patients demanded the test by themselves. Not surprisingly, the reported most important features of POC Strep A tests were rapidity, reliability and specificity which were accomplished by QuikRead go Strep A.

²Primary Care Center "La Paz", Badajoz, Spain.

³University Hospital Complex, Badajoz, Spain.

One morning on June, came to our consulting room, María. She's 50 years old, and she hasn't got any medical history. Her father died due to an ischemic heart disease.

She was worried about a sudden chest pain radiated to her back, accompanied with palpitations, shortness of breath and nausea, lasting 3 hours. She had a similar episode 2 days ago, and in the last week, she has been having insomnia because of an important emotional stress.

In that moment, the physical examination revealed: blood pressure 90/50, heart rate 110, oxygen saturation 90%; crackles heard in lung bases, with no more signs. We performed an electrocardiogram that revealed an inverted T wave in I, aVL, II, III, aVF, V2-V6, QTc 492 ms.

After this results, we decided to derive her our Referral Hospital, with the suspicion of Acute Coronary Syndrome with left heart failure signs.

The laboratory results highlighted an elevated troponin and creatinine kinase-MB, and a normal chest x-ray. Then, the echocardiogram showed an akinesia of the apical and mid-ventricular segment while the basal segments were hypercontractile, with 35% ejection fraction. Coronariography was normal, and ventriculography showed an apical ballooning akinesia with basal hyperkinesis.

The diagnosis was Takotsubo cardiomyopathy (TC).

The treatment of TC is generally supportive (bradycardia and low blood pressure); she was discharged after 7 days with this treatment: a beta-blocker (2 times/day) and a de-aggregating agent (1 time/day).

TC is a transient cardiac syndrome that involves left ventricular apical akinesia and mimics acute coronary syndrome. It was first described in Japan by Sato. Patients often present with chest pain, have ST-segment elevation on electrocardiogram, and elevated troponin levels consistent with a myocardial infarction. However, when the patient undergoes cardiac angiography, left ventricular apical ballooning is present and there is no significant coronary artery stenosis.

Pulmonary Thromboembolism in Patient That Admitted With Atypical Clinic: A Case Report

Zeynep Sayın Dincer¹, Gökhan Dincer², Aybüke Demir Alsancak¹, Duygu Ayhan Başer¹, Hatice Küçükceran¹, Yakup Alsancak³, İrfan Şencan¹, İsmail Kasım¹, Rabia Kahveci¹, Adem Özkara⁴

³Ankara Atatürk Training and Research Hospital, Department of Cardiology

⁴Hitit University Faculty of Medicine, Department of Family

INTRODUCTION: Pulmonary thromboembolism (PTE) is a major clinical problem that has a high mortality and morbidity. For the diagnosis of PTE, firstly physicians should suspect the disease. PTE is a difficult disease to diagnose because of the illusive, nonspecific and varied symptoms upon presentation. The major challenge for primary care is the lack of equipment for definitive diagnosis of the condition and all patients suspected to have a PTE must be referred to a higher center. We aim to present an interesting case of PTE in this case report and would like to discuss management of the condition in primary care.

CASE: Seventy-two-year-old woman was admitted to our outpatient clinic of outpatientclinic of with cough that has started a week ago. She had effort dyspnea for 3 years but recently there has been no significant increase in dyspnea noticed. Also she had stabbing pain on left side of back. She has no chronic disease history other than

COPD. She had a blood pressure of 140/85, heart rate 82, respiratory rate 18, temperature 36.1 C. Her chest examination revealed rhonchi bilaterally, but was clear at percussion. No accessory muscle use was noticed and there was no sign of cyanosis. Rest of the physical exam did not reveal anything remarkable. Laboratory data revealed an elevated white blood cell, sedimentation rate and CRP. There was a clinical suspicion for PTE in the patient because she was obese and we measured D dimer and determined elevated. (352ng/ml) Diagnosis of PTE was confirmed by CT angiography.

CONCLUSIONS: PTE has a wide range of courses from asymptomatic to sudden death. Except patients have the highest degree of clinical suspicion, it is also possible to diagnose pulmonary embolism in patients with non-specific clinical findings. To identify these patients may prevent pulmonary embolism induced morbidity and mortality.

Single-Dose Intramuscular Methotrexate Treatment of Ectopic Pregnancy

Ahmet Ünal¹, Burcu Bıçakçı², Hamit Alper Tanrıverdi², Yetkin Şentosun¹

¹Department of Family Physician, Adnan Menderes University, Aydın, Turkey

²Department of Obstetrics and Gynecology, Adnan Menderes University, Aydın, Turkey

INTRODUCTION

Ectopic pregnancy is the most common life-threatening condition in early pregnancy. Implantation elsewhere is considered ectopic and comprises 1 to 2 percent of all first-trimester pregnancies in the United States. The ampulla is the most frequent site, followed by the isthmus. Ectopic pregnancy is the leading cause of first trimester pregnancy-related morbidity and mortality (38 deaths/100,000 events). It is a life-threatening pregnancy complication; so early diagnosis becomes very important in treatment. Diagnosis is based on a combination of ultrasonographic findings, consecutive levels of human chorionic gonadotrophin (hCG) and also clinical suspicion.

CASE REPORT

A 33-year-old woman presented with irregular and scanty bleeding with occasional abdominal pain for 3 days. There was 2 history of missed periods. She had a period of amenorrhea of 5 weeks and 3 days before which her menstrual cycle was regular with normal flow. She has had two full-term vaginal deliveries. There was no history suggestive of pelvic inflammatory disease, previous laparotomy or intake of fertility-enhancing drugs.

On examination, the patient was pale, although her vitals were stable. Her pulse rate was 78 beats/min, and blood pressure was 130/ 80 mm Hg. Her abdomen was soft; there was no tenderness or guarding. In pelvic examination there was no bleeding per vagina. Beta hCG was 657.71 mIU/mL.

Pelvic sonographic examination was done to localize this pregnancy, the uterine cavity was found empty and there was massive pelvic fluid collection. Beta hCG was 737.11 mIU/mL. The diagnosis of ectopic pregnancy was diagnosed.

Single-dose protocol of methotrexate (50 mg/m²) is administered intramuscular on day 1, and the hCG value is measured 647.86 mIU/mL and 354.25 mIU/mL respectively on days 4 and 7.

CONCLUSION

In primary care, Early diagnosis of ectopic pregnancy would be life-saving.

Listen to Young Hearts

Rana Gundogan, Kubra Uyar, Burcu Aslan, Nilgun Ozcakar
Department of Family Medicine, Dokuz Eylul University, Izmir, Turkey
Background&Aim

Palpitation is a disturbing feeling of heartbeats and hard work, sleep disorders, stress, alcohol&smoking and over-consumption of tea and coffee are common causes. Patients with palpitation for any reasons (cardiac, psychological, systemic such as hyperthyroidism, anemia..) should be evaluated by electrocardiogram(ECG) of first priority. Wolff-Parkinson-White(WPW) Syndrome is a birth defect causes tachycardia, evolved by an additional electrical path. Seen in society is 1/100000 and more on males, cause palpitations, dizziness, syncope, dyspnea, chest pain and rarely(less than %1) ventricular fibrillation and death. Our goal is to draw attention to evaluation of young patients with palpitations.

CASE: No known disease, 21-year-old female medical student was admitted to emergency complaining of palpitation. She felt palpitation 2 hours before at home and noted blood pressure:130/80mmHg, pulse rate:165/min. It's the first time that she had palpitations and stated that she had been exercising since 1 year, consumed more coffee recently and was under intense stress during her examination dates. At her application; blood pressure:125/80mmHg, heart rate:78/min and body temperature:36.6°C. Physical examinations found regular including cardiac examination.

ECG:Sinus rhythm, Heart rate:83/min, PR<0.12sec and delta wave at the beginning of QRS complex. Hb:13.2g/dL, WBC:8.0x10³/mm³, LFT, KFT, CRP, electrolytes and cardiac enzymes are normal and blood glucose was 64 mg/dl. After held 8 hours in cardiology consultation with diagnosis of WPW Syndrome, she was discharged by recommendation of 24-hour Holter ECG control and no medical treatments were recommended.

Discussion and CONCLUSION:

Some arrhythmias can be simple while cause of others is serious. ECG evaluation after physical examination and a careful cardiac examination has a great importance on young patients who come with palpitations without thinking it's caused by neither psychological complaints nor stress&caffeine.

Family physicians should be cautious on patients who have the symptoms of arrhythmia. These symptoms should be assessed in detail, regardless of any health-care condition.

Keywords: Palpitation, WPW Syndrome, arrhythmia

³University Hospital Complex, Badajoz, Spain.

⁴Primary Care Center "San Roque", Badajoz, Spain.

⁵Primary Care Center "Pueblonuevo del Guadiana", Badajoz, Spain.

José is a 50 years old man, with a history of hypertension and dyslipidemia, with no more previous illness. He came to our consulting room worried about an intense lower back pain, radiating to the lower limbs, because of an important effort performed 3 days ago. Besides, he's feeling numbness in both feet and pelvic girdle, intermittently, and difficulties to walk and at the beginning of urination.

The physical examination revealed: blood pressure 150/80, oxygen saturation 98%, heart rate 75, without fever. The neurological examination was abnormal: patellar hyperreflexia in both sides, with an absent achilles reflex;

left foot dorsal flexion 1/5 and right 0/5; left foot plantar flexion 1/5 and right 0/5; no loss of sensitivity in lower limbs; negative Lasegue; the rest of examination is within normal limits.

With the suspicion of some medullary disease, we decided to derive our patient to the Emergency Room to complete the study.

There, the tests results were normal, including an electrocardiogram and a chest and an abdominal x-ray. In spite of that, the decided to perform a magnetic resonance objetifying a lumbar disc herniation at the level of L4-L5.

The diagnosis was Cauda Equina Syndrome due to a lumbar disc herniation. When the diagnosis was clarify, an urgent surgery was indicated (partial laminectomy and resection of disc herniation), with significant functional recovery in the following days.

CES is a rare condition, with serious consequences if not treated promptly. It is most often caused by a large disc herniation in the lower back that compresses the nerve roots. Unlike most back problems that are longstanding or chronic, CES is an acute event which develops rapidly, within 6-10 hours. Classic symptoms of back pain, coupled with a sudden onset of numbness in the genital area and urinary retention. Relieving compression quickly is decisive.

Keywords: Low back pain; Cauda equina; Intervertebral Disc Displacement.

Ruptured Pacemaker Lead-Induced Repetitive Case Of Infective Endocarditis

Yaşar Koşar¹, Esengül Ünal¹, Ahmet Akçay², Mustafa Çelik¹, Mustafa Haki Sucaklı¹

¹Department of Family Medicine, Kahramanmaraş Sütçü İmam Universty, Kahramanmaraş, Türkiye

²Department of Cardiology, Kahramanmaraş Sütçü İmam Universty, Kahramanmaraş, Türkiye

INTRODUCTION: Pacemaker endocarditis is a life-threatening condition, early diagnosis and timing of treatment is important.

CASE: 37 year old male patient was admitted to our clinic with complaints of cold, rising fever with chills continued for a week. His past history, in 1998 he had been operated for ventricular septal defect and permanent pacemaker had been implanted. We learned that the rupture of the pacemaker lead was detected and a new pacemaker was re-implanted to him when he was presented to the hospital with complaining of palpitations and fatigue in 2003. Patient had been admitted to hospital again with complaints of fever, chills, cold and he had received medical treatment with the diagnosis of infective endocarditis in 2009.

During the last one week, patient had complaints of fever, chills, sweating and he was presented to emergency service. He hospitalized with the suspicion of infective endocarditis. His temperature was 38.2°C. Laboratory studies: white blood cell count 15900/mm³, erythrocyte sedimentation rate 40 mm/hour, C-reactive protein (CRP) 86 mg/dl.

Transthoracic Echocardiography: Around the pacemaker lead, there were mobile and immobile vegetations.

Blood cultures were taken 3 times in the first 24-hour period. 4*500 gr vancomycin, 2*160 mg gentamycin were started intravenously. On the second day, Staphylococcus hominis of coagulase negative staphylococci was

identified from blood cultures. After the medical treatment CRP and leukocytes decreased to normal levels. Patient was transferred to the heart and vascular surgery clinic for surgical removal of pacemaker leads and battery.

Discussion and CONCLUSION: In primary care, family medicine clinics are quickly and easily accessible units by individuals and have an important position in terms of early diagnosis of infective endocarditis, rapid organization of treatment, periodic evaluation of the patients in the risk groups and presentation of preventive health services.

¹⁰Marmara University Department of Family Medicine İstanbul

Since the end of 2010, transition in primary care has been completed and it's now assumed that every citizen has a "family doctor" in Turkey. There are 21,750 family doctors in Turkey. Only 1048 (4.9 %) of the family doctors have post graduate training, so called specialists in family medicine. It is mandatory by legislation to have a defibrillator in 6,756 family healthcare centers throughout the country. However, family doctors once general practitioners came from different facilities to work in primary care. Some had no experience in emergency medicine. We aimed to analyze the knowledge level of family doctors in cardiopulmonary resuscitation (CPR) and their attitude toward it in order to help health managers to better evaluate the necessity of a country-wide post-graduate education program on this matter.

These are preliminary RESULTS: We have interviewed face-to-face with 164 family doctors and 15 emergency medicine specialists so far with a questionnaire consisting of 15 multiple-choice questions prepared from latest CPR guideline by a selective group of academicians in emergency medicine seeking for information and 15 questions about their attitude towards CPR. Questions were targeted especially to the topics recently changed substantially in order to analyze how up-to-date the doctors were. The results of family doctors and emergency medicine specialists were compared. We found that the correct number of answers were $5,6 \pm 2,9$ (max:13 min:1) in family doctors group and $10,66 \pm 2,6$ in emergency medicine specialists group. The difference between the groups in terms of giving correct answers was significant. ($p < 0,0001$)

Our preliminary results clearly suggested that primary care doctors in Turkey are outdated in terms of CPR. A country-wide training seems to be necessary to correct this issue.

After Trauma: Acute Appendicitis or Not?

Özden GÖKDEMİR¹, Eren Güzeloğlu², Nilgün Özçakar¹

¹Dokuz Eylül University, Medical Faculty, Family Medicine Department, İzmir, Turkey

²Dokuz Eylül University, Medical Faculty, Pediatrics Department, İzmir, Turkey

Appendicitis is the most common condition in children requiring emergency abdominal surgery. A successful outcome would be early diagnosis followed by appendectomy before gangrene or perforation develops. Older children and adolescents develop appendicitis more often than younger children. Their clinical features are similar to those seen in adults. Laboratory testing and imaging studies, primarily ultrasound and computed tomography or magnetic resonance imaging, are helpful adjuncts in selected children undergoing evaluation for appendicitis. One of the differential diagnosis is cystic lesions of the liver. This represents a heterogeneous group of disorders. Most liver cysts are found incidentally on imaging studies and tend to have a benign course. Larger cysts are more likely to be symptomatic and cause complications. The rupture into the peritoneal cavity or bile duct, infection or compression of the biliary tree are some of them. However cystic lesions could be lung lesions, too.

CASE: 15 year-old Caucasian boy has attended to the pediatrics emergency service because of his stomach ache. In history of patient; he was assaulted by a school friend 5 days ago and he had vomiting, abdominal pain for 3 days. He was suspected as appendicitis at another health center. Due to the trauma history of the patient; contrast-enhanced CT examination of the thorax and abdomen has been made. The findings were considered as the rupture of cystic hydatid. He was diagnosed as rupture of a lung hydatid cyst. There's no finding of acute pancreatitis.

CONCLUSION: "Acute abdomen" is a common reason to attend at health centers. To manage this paradigm is not only the response of emergency service health workers but also the GPs/FMs. The objective is to describe a patient with hydatidosis, who seemed to be acute pancreatitis and with a trauma history is the best way to manage the case to take patient history and physical examination.

Keywords: cyst hydatid, traumatic rupture, lung hydatid, acute abdomen

Thorax CT

The sections were evaluated with pulmonary parenchymal window, the long axis of the left lung lower lobe (craniocaudal) cystic membrane detachment in the air and about 10 cm measured changes in the structure and showed atelectasia. There's pleural effusion on the left hemithorax, reaching up to 3 cm thick at the widest part and in the basal segments was observed thickening of the pleura. The findings were evaluated primarily as cystic hydatid rupture. Pancreas, spleen, liver, both kidneys placement in the section of the abdominal parenchymal density levels were normal.

P-0357**Efficiency of management of urinary tract infections at a university hospital family medicine outpatient clinic**

Zehra Dağlı, Duygu Ilke Yıldırım, Ayşe Selda Tekiner, Ayşe Gülsen Ceyhun Peker, Mehmet Urgan
Department of Family Medicine, School of Medicine, Ankara University, Ankara, Turkey

OBJECTIVE: Urinary tract infection (UTI) is one of the most common bacterial infections that can be managed at primary care setting. The study aimed to determine whether the patients with pre-diagnosis of UTI were investigated and treated adequately at a university hospital family medicine outpatient clinic.

METHODS: Retrospective, descriptive, cross-sectional study included the patients who applied to Ankara University İbni Sina Hospital Family Medicine outpatient clinic and were pre-diagnosed for UTI for the first time between January 2013 and December 2014. Descriptive statistics were given as mean±standard deviation and percentage. Chi-square test was used for differences between the groups. Any $p < 0.05$ was considered statistically significant.

RESULTS: Mean age of 177 patients (10.7% male, 89.3% female) was 36.80 ± 17.70 years. Only 83.6% had symptoms. While the most common symptoms were dysuria (58.7%), nausea (22%), and frequency (14.6%), 32.7% of the patients had two or more symptoms. Blood, urine, and imaging tests were performed in 94.4%. The most common tests utilized were urine analysis (dipstick and microscopy) (93.2%), complete blood count (CBC) (57.6%), and urine culture (53.7%), and majority of the patients (79.6%) were investigated with two or more tests. Only comparisons between treatment choice and presence of symptoms, urine analysis results, and urine culture results were statistically significant. Of the patients with symptoms, 55.4% were treated with antibiotics, but 30.4% received no treatment ($p = 0.004$). Antibiotics were choice of treatment in 65.8% of the patients with urine analysis results indicating UTI, whereas 23.7% of those remained untreated ($p = 0.018$). While 81.5% of the patients with growth in urine cultures were treated with antibiotics, no treatment was given to 14.8% ($p = 0.018$).
CONCLUSION: The results of the study suggested that UTIs were managed quite efficiently. Yet, guidelines for UTIs should be followed carefully to treat the patients properly and to prevent emergence of resistance to antibiotics.

Keywords: urinary tract infection, management, primary care

P-0358**Neurological Side Effects Caused by Lithium Toxicity: A Case Report**

Esra Ceylan¹, Pınar Şen Gökçeimam², Mehmet Fatih Akdoğan³, Gül Babacan Abanonu³

¹Department of Family Medicine, Beyhekim State Hospital, Konya, Turkey

²Department of Psychiatry, Erenköy Training and Research Hospital for Psychiatry, Istanbul, Turkey

³Department of Internal Medicine, Haydarpaşa Numune Training and Research Hospital, Istanbul, Turkey

AIM: Lithium has been commonly used for the treatment of several mood disorders particularly bipolar disorder over the last 60 years. Lithium has been shown to accumulate especially in nerve cells; it is known that side effects occur at normal serum lithium levels even at non-therapeutic levels in the central nervous system. The aim is to emphasize the importance of diagnosing of neurological side effects of lithium in a 55-year-old female patient with a history of schizoaffective disorder.

CASE: A 55-year-old woman with 15-year history of schizoaffective disorder was staying in the nursing home for 6 years. The patient presenting to Haydarpaşa Numune Training and Research Hospital was taking lithium 600 mg/day, olanzapine 10 mg/day, chlorpromazine 100 mg/day due to general poor health and lack of oral intake for the last three days. The patient's physical examination revealed that vital signs were normal, but she opened her eyes briefly while calling but not willing to cooperate, had dehydration, significant rigidity and gearwheel. The laboratory examinations were as follows: creatinine; 1.23 mg/dL, creatinine clearance; 63.56 ml/min, uric acid 1.6 mg/dL. Liver, thyroid function tests, complete blood count, serum electrolytes, glucose, blood gases, creatine kinase (CK), CK-MB values were within normal limits. The patient had no acute pathologic findings on non-contrast-enhanced cranial computed tomography. ECG showed sinus rhythm and was within normal limits. Serum

lithium level was 2.21 mmol/L(Normal:0,6-1.2 mmol/L).We learned that she was not taking the drugs regularly prior to admission to our hospital.No growth was observed in urine, CSF, blood cultures.Lithium level decreased 0.05 mmol /L following treatment with 0.9% NaCl infusion and forced diuresis (4000 cc of saline daily).At discharge creatinine 0.58 mg/dL, creatinine clearance;113 ml/min, she had orientation and cooperation, and with no rigidity, gearwheel findings.Specialists in psychiatry diseases prescribed the drugs.
RESULT: Considering the frequent use of lithium, its adverse effects on the nervous system should not be ignored.

Keywords: Lithium, neurological side effects, intoxication

P-0359

Clinical Case - Are corticosteroids recommended in acute urticaria?

Maria Teresa Pereira Rodrigues Gaudêncio Silva¹, João Pedro Tomaz²

¹Maria Teresa Silva

²João Tomaz

Context: Antihistamines and intravenous corticosteroids (CC) are commonly used for preventing emergent episodes of acute urticaria symptoms such as anaphylaxis and laryngitis angioedema.

CASE: 81 years old male, married, in a nuclear middleclass family household, with clinical history of hypertension, dyslipidaemia, allergic rhinitis and benign prostatic hyperplasia. Medicated with acetylsalicylic acid, enalapril, esomeprazole, simvastatin; no known allergies. Came to consultation by the Family Physician due to maculopapular pruriginous rash on the torso; diagnosed as urticaria and medicated with intramuscular 200mg hydrocortisone and clemastine. On outpatient service, was medicated with ebastine administered twice a day. Returns to consultation 3 days later due to dissemination of urticary-like plaques, new edema on both hands and periorbital area, being referenced to appointment by dermatology; further medicated with 20mg prednisolone for 5 days and 25mg hydroxyzine which kept for over 2 weeks following the disappearance of symptoms.

DISCUSSION: Despite urticary being a frequent form of anaphylaxis (80% to 90% displaying skin manifestation) such situation is emergent but also rare and expectably related to immediate contact with the allergen (maximum up to 2 hours), being treated with adrenaline. Angioedem, may or may not present itself alongside urticaria, larynx angioedema being the most frequent. Acute urticaria usually presents a benign evolution, symptoms being controlled within 24 to 72 hours. Second generation antihistamines are the first line of treatment and dosage may be increased by 4 times the usual amount. Single dosage use of corticosteroids is often associated with exacerbation of initial urticaria symptoms (rebound effect), wich may have been the case in the clinical situation presented above. Such treatment must be reserved to situations of exacerbation, non-responsiveness to antihistamines or urticaria associated with angioedema and should only be applied over a very short period (3 to 7 days). Keywords: acute urticaria; corticosteroids

Patient's urticary-like plaques on the torso.

Rare and interesting cause of acute coronary syndrome

Turyan Abdulhalikov¹, Hakan Akilli³, Ayşe Yilmazer², Tuncer Kılıç²

¹Department of Cardiology, Bilgi Tıp Merkezi, Ankara, Turkey

²Department of Family Medicine, Yıldırım Beyazıt Üniversitesi, Ankara, Turkey

³Department of Cardiology, Necmettin Erbakan Üniversitesi,

Acute coronary syndrome (ACS) is a life-threatening emergency. Kounis syndrome includes both severe allergic reactions and acute coronary syndrome.

A 48-year-old gentleman admitted to the emergency department (E.D) with sudden cardiac arrest after a bee sting. He did not have any history of previous cardiovascular disease, and other major risk factors. At the E.D patient was intubated and lost consciousness. His systolic blood pressure was 65 mmHg. Immediately inotropes and fluid replacement were administered. An electrocardiogram revealing ST elevation in inferior leads and reciprocal depression (fig-1). In coronary angiography normal coronary arteries were observed (fig-2,3,4). After coronary imaging another cause of sudden cardiac arrest (such as acute aortic dissection, acute pulmonary embolism and intracranial hemorrhage) were excluded. Several days later patient died due to lactic acidosis and multi-organ failure.

There are no uniform guidelines in this syndrome and all data were derived from case reports and personal experiences. Two types of Kounis syndrome are present. Kounis syndrome is a manifestation of endothelial dysfunction due to severe coronary vasospasm. Aspirin should be administered to all patients with ACS but unfortunately it may cause allergic reactions and induce anaphylaxis. Therefore the utility of aspirin in Kounis syndrome is uncertain. If it is not contraindicated an oral beta-blocker should be administered. Coronary spasm is very responsive to calcium channel blockers so in Kounis syndrome they may be first-line when an anti-ischemic drug is needed. In the absence of contraindications nitrates are recommended for persistent ischemia. In ACS heparins are indicated but both can cause allergic reactions. The management of anaphylaxis in ACS patients is another challenging problem. Fluid replacement is essential in the treatment of anaphylaxis. In ACS, severe left ventricular dysfunction may be possible so volume overload must be avoided.

Finally, more investigation is needed for the treatment of this situation.

MERS VIRUS and UMRAH VISIT

Kubra Uyar, Rana Gundogan, Nilgun Ozcakar
dokuz eylul university, department of family medicine

Introduction and OBJECTIVE: Corona virus family is major pathogens of human and animals. Mers virus, a member of this family is cause of 1/3 of community acquired upper respiratory diseases and possible causes of severe respiratory disease in both adult and children. Virus source is not exactly known but some assumptions about bat and camels. Diseases caused by virus have usually seen in Saudi Arabia, Qatar, Jordan and United Arab Emirates. Incubation period is 9-12 days and shows similar symptomatology with upper and lower respiratory tract infections: fever, cough, respiratory distress, sore throat.

Laboratory: pancytopenia, elevated ALT, AST, urea, creatinin and LDH levels. In almost all cases radiology is varying minimal lesions to large pathologies: increased bronchovascular image, opacities in the airways, reticulonodular shadows.

CASE: 23 year old female patient was admitted to emergency with cough, sweating, weakness, sore throat and respiratory distress. Patient's vital FINDINGS: Blood pressure: 130/85 mmHg, heart rate: 86/min, body temperature: 38°C, O₂ saturation: 96%. In detailed history learnt that she returned from a visit to Umrah 3 days ago. Complaints have started 4 days before and painkillers didn't make any decline in complaints.

Pharynx was hyperemic, tonsils were hypertrophic and there were bilateral crackles in both lower zones.

Hb: 13,7 g/dl WBC: 15x10³/mm³, Plt: 230x10³/mm³, CRP: 65. Liver enzymes, urea-creatinin and serum electrolyte levels were normal. In chest X-ray there were paracardiac infiltrations. Consulted by infectious disease department, pre-diagnose of Mers virus infection. Infectious disease department decided to take endotracheal aspirate, sputum samples and received disease pursuit.

Discussion and RESULTS: Upper and lower respiratory tract infections takes priority among the reasons to refer primary care physicians. Fever, cough, fatigue, sore throat symptoms are initial symptoms of respiratory infections but underlying disease can occur with similar symptoms. Family physicians should evaluate each patient taking their detailed history. Infectious diseases which have high mortality should firstly followed by family physicians before a specialist!

Anaphylaxis related to bee sitting

Ahmet Ünal¹, Ayşe Yenigün², Faruk Demir²

¹Department of Family Medicine, Adnan Menderes University, Aydın, Turkey

²Department of Pediatric Allergy and Immunology, Adnan Menderes University, Aydın, Turkey

INTRODUCTION

Anaphylaxis is a life threatening reaction that occurs in between 0.05 to 2% of the general population. It is estimated to cause death in 1 to 3 per million people. Pathophysiologically, it is mediated by substances released systemically during mast cell and basophil degranulation, which cause increased vascular permeability, tachycardia, bronchospasm, pruritus, rhinorrhea, vasodilation, hypotension, flushing and headache.

CASE REPORT

We report the case of a 8-year-old girl who developed anaphylaxis after bee sting. The patient has spring allergies, and no family history of allergic disease. She has under the eye edema at 30 minutes later bee sitting. In the other hospital, dexamethasone and pheniramine was injected to patient.

On examination, extremities were cool, and there was an urticarial rash involving the lower limbs. His heart rate was 108 bpm and regular, his blood pressure was 100/60 mm Hg and his respiratory rate was 28/min.

Auscultation reveals bilateral diminished sibilant rhonchi. Physical examination was otherwise unremarkable. Laboratory investigations revealed elevated erythrocyte sedimentation rate (ESR) (42 mm, normal range 0-20 mm) with normal full blood count and serum biochemistry. Chest x-ray and electrocardiogram (ECG) were

normal.

A diagnosis of anaphylaxis was then made. The patient was treated with IV fluid, steroids, antihistamines and IM epinephrine. The patient was discharged from the hospital 5 days after hospitalization.

CONCLUSION

Anaphylaxis can present with similar features to other life-threatening medical emergencies with the cardinal features of hemodynamic compromise, cardiac dysfunction and hypoxia, as well as abnormal investigation results. Careful clinical assessment is important so that appropriate treatment can be instituted promptly to avoid further morbidity and mortality. Epinephrine is the first and most important treatment for anaphylaxis; considering its relative safety, when in doubt, epinephrine should be administered.

Bullous Erythema Ab Igne: A case report

Ömer Göcen¹, İsa An², Hamza Aslanhan¹, Vasfiye Demir¹

¹Department of Family Medicine, Dicle University, Diyarbakır, Turkey

²Department of Dermatology and Venereal Diseases, Dicle University, Diyarbakır, Turkey

INTRODUCTION: Erythema Ab Igne (EAI) is a cutaneous, macular dermatosis caused by chronic and repeated exposure to heat which initially presents with erythema and telangiectasia and later develops a reticular pigmentation which is also precancerous. EAI is associated with chronic use of hearths, stoves, hot water bottles, electric blankets, and laptop computers. We present a case with bullous erythema ab igne caused by the use of electric heaters.

CASE: A 19-year-old man presented to the family physician with a brown discoloration skin with several bullae on the right leg existing for 15 days. The patient had no history of chronic disease and drug use. He had used an electric heater for heating his legs for over 1 hour each day over the last two months. The patient was consulted to Dermatology and the examination revealed multiple hyperpigmented brown regions with a reticular, livedoid appearance and bullous lesions on the anterior surface of the right leg (Figure 1). Laboratory examinations were normal. Punch biopsy was performed on the lesions. Mild atrophy in epidermis, vacuolar alteration at the basal layer, and mononuclear cell infiltration in the upper dermis and the patient was diagnosed as having bullous erythema ab igne. No treatment was performed and the patient was only followed up.

DISCUSSION: EAI is a dermatosis caused by long-term and chronic exposure to heat which can present as pigmented, reticular and also telangiectasic. EAI is more common in patients with hypothyroidism; however, the association of EAI with systemic diseases remains unknown. EAI is easily diagnosed due to its characteristic clinical manifestations. The lesions in EAI are often asymptomatic and rarely bullae occur on the lesions. The development of Merkel cellular carcinoma or squamous cell carcinoma is the most important complication. Common treatment includes hydroquinone, topical steroids, topical retinoids, and Nd:YAG laser.

Keywords: ab, erythema, igne

A Case: Paraquat (Pesticide) and Skin Involvement

Bahadır Yazıcıoğlu, Füsün Ayşin Artıran İğde

Department of Family Medicine, Faculty of Medicine, Ondokuz Mayıs University, Samsun, Turkey

Introduction

Pesticides are chemical materials used in order to destroy or decrease the harmful effects of creatures such as insects, weeds, fungi and rodents which survive in and around the human habitat and decrease the nutritional value of agricultural nutritional sources or harm them. Paraquat is a pesticide which was started to be used in agriculture and gardening around the world since the middle of 1960's and considered industrially safe. Paraquat taken in the body mostly orally and transdermal, inhalation and although rarely intravenous way is a dipyridinium compound which may cause poisoning. It causes erythema, swelling and ulceration on the skin.

Case

Erythema, itching, swelling and bullae with exudative discharge in almost all of the left foot and leg was observed in a 56 year old man for fifteen days. On the day his complaints started, he used agricultural pesticide while it was raining. The erythema in his left ankle started to spread upwards toward his knee in 2-3 days. His itching became very intensive.

The patient was in a good general condition. Significant amount of edema, hemorrhagic erythema and burst bullae were present under the left knee. The patient was put on bed rest. Left leg elevation and ice compress for 15 minutes at least two times a day was given in order to decrease edema. Consultation was made with dermatology department and steroid treatment was given in order to decrease inflammatory effect. Topical and systemic anti-biotherapy was started. Hemorrhagic lesions started to scab on the third days after resting and treatment were started. The cure was completed in two weeks.

Discussion

Paraquat taken in the body mostly orally and transdermal, inhalation and although rarely intravenous way. Especially learning the exposure way by anamnesis and providing an anti-inflammatory and symptom-based treatment would be appropriate for these patients.

Sudden cardiac arrest, Long QT syndrome, Arrhythmia

Ahmet Ünal¹, Semiha Terlemez², Ebru Ataş Aslan³, Deniz İncaman¹, Yasin Bulut³

¹Department of Family Medicine, Adnan Menderes University, Aydın, Turkey

²Department of Pediatric Cardiology, Adnan Menderes University, Aydın, Turkey

³Department of Pediatrics, Adnan Menderes University, Aydın, Turkey

INTRODUCTION

Sudden cardiac arrest, sudden finish or stoppage of the heart's pumping function. The most common cause of sudden cardiac arrest in children; acute myocarditis, cardiomyopathy, cyanotic and non-cyanotic congenital heart disease, valvular heart disease, congenital complete heart block, Wolf-Parkinson-White syndrome, long QT syndrome, Marfan syndrome, coronary artery disease. We present our experience applying returned with cardiopulmonary resuscitation (CPR) from a 12-year-old patient, who is here with no known health problems before.

CASE REPORT

When entered the room in the morning by the family of our patient, has been noticed that his breathing and 112 emergency medical services were sought. Patient is diagnosed as pulseless cardiac arrest and applied CPR. In our hospital, he turned sinus rhythm into 30-minute emergency resuscitation results. Glasgow Coma Scale score is 8, patients in neurological assessment; pupillary regular, bilateral and corneal light reflex. Unable to retrieve the patient's deep tendon reflexes, Babinski were negative on the and right positive on the left. Cranial magnetic resonance imaging (MRI) and diffusion MRI of the brain was normal. It is not a disease known prior to our patients, not drug use, had learned that exposure to pesticides. After cardiac arrest that may cause respiratory and neurological causes were excluded focused on cardiac causes. Echocardiography was normal. When questioned in terms of long QT syndrome, deafness and in patients with a history of syncope, there was no family history of sudden cardiac death. But it is in the patient's ECG electronically calculated QTc0,36 Bazzet state formula calculating the QTc intervals were calculated with 0,54. Other ECG findings, normal sinus rhythm, heart hızı 112/min, PR: 0,12 sec QRS was evaluated as 0,06 sec. Because patients with a history of drug use that could

cause QT interval length and head trauma, congenital long QT syndrome was not considered. The patient's laboratory values were normal value except (table-1). High-dose β -blocker therapy was started to patient. The patient was referred to another hospital and ICD fitted. The patient's mother in the long QT (QTc490ms) were, β -blocker therapy was started.

CONCLUSION

Should be seen firstly electrocardiogram of patients by us, that sudden presenting cardiac arrest and syncope, must be evaluated in terms of long QT syndrome. QTc should be calculated with Bazzet formula (QT/VR) for an accurate diagnosis.

³Samsun Maternity and Children's Hospital, Department of Pediatric Surgery, Samsun, TURKEY

⁴Atakum Community Health Center Samsun, Samsun, Turkey

Serious Hypoalbuminemia Detected in Two 8 and 9 year old Child Cases with different degrees of Parapneumonic Pleural Effusion were covered in this study. In the clinical complaints of the patients, a dramatic recovery was observed after albumin treatment.

Case 1

An eight year old male patient was taken to the hospital with breathing difficulty, fever and coughing complaints. There was a decrease in pulmonary auscultation. C-reactive protein (CRP) level was 38.2 mg/dl and erythrocyte sedimentation level was detected as (ESR) 40 mm/h. Oxygen, IV vancomycin and ceftriaxone were given to the patient. Parapneumonic consolidation and pleural effusion were detected in thoracic usg pulmonary CT and chest tube was located. The albumin level in the liquid taken was measured 2.2 g/dl and serum albumin level was measured 3.2 g/dl. On the eighth day, the albumin level decreased to 1.7 g/dl and on the tenth day, 1 g/kg IV albumin was replaced. The level increased to 2.6 g/dl and a dramatic decrease was observed in pleural collection in the follow-up and the patient whose complaints were over was discharged on the 15th day.

Case 2

A 9 year old male patient was presented with fever, cough, breathing difficulty and chest pain. Pulmonary auscultation had decreased. ESR 70 mm/h and CRP level was determined as 46.9 mg/dl. In thoracic usg, parapneumonic consolidation and pleural effusion were observed and thoracentesis was applied. IV vancomycin and ceftriaxone were started. Serum albumin levels were found 2.0 g/dl on second and third days. 1 g/kg IV albumin was replaced daily on the fourth day. The patient who had a dramatic recovery in clinical findings was discharged on the 14th day.

As albumin treatment effectivity was observed in this study, it was considered as a good parameter in the related disease follow-up.

Clinical Results and the Gait Parameters after Total Hip Arthroplasty Surgery

Ahmet Yıldırım¹, Selçuk Bölükbaşı¹, Erdiñç Esen¹, Ulunay Kanatlı¹, Duygu İlke Yıldırım²

¹Gazi University Medical School Orthopaedics and Traumatology Department

²Selçuk University Medical School Family Medicine Department

We were looking for the clinical results and the differences at the patients who had unilateral total hip arthroplasty surgery with two different lateral surgical approaches. We analyze three different parameters between the patients; first, the plantar pressures by the help of dynamic pedobarography, second Trendelenburg's sign and third cilnical results by Harris hip score.

We selected 28 patients who had been operated in our clinic; Gazi University Faculty of Medicine, Department of Orthopaedics

and Traumatology. Plantar pressures have maesured by EMED-SF pedobarography device; that seperates the foot to the four different parts which are called masks. Trendelenburg's sign has been estimated as grade 1 and grade 2 by the method which was described by Hardcastle and Nade. Clinical outcome was measured by comparing Harris Hip Scores pre-operatively and at last clinic visit. All the parameters were compared as preoperatively and postoperatively at the sixth month. SPSS 15.0 was used to analyze the results.

In both groups after the six months from the surgery; total contact time has increased at the operation side when the results were compared before the surgery at the same side and at the other side after the surgey. Also when we looked at the first and second masks which show the significant part of the stance phase; contact areas have

similarly increased and the changes at the peak pressures were similar as contact areas.

For whole the patients the average preoperative Harris hip score was 41,50 points. At the time of the last visit, the average Harris hip score was found as 86,68 points.

The functional and clinical early results are similar in both when superior gluteal nerve protection, conjoint tendon repair and postoperative rehabilitation have done well. Pedobarography is an effective, cheap and easy way to analyse the changes at the hip muscles.

Migraine and Puberty

Nevruz Yıldırım, Hakan Demirci, Beyza Demirbaş, Mehtap Gömleksiz

Department of Family Medicine, Sevket Yılmaz Training and Research Hospital, Bursa, Turkey

Background

Migraine is an important public health problem, especially for the young people. Its frequency is high and it causes disability and loss of performance. In this study, our aim was to examine relationship between migraine headaches and puberty among school age children in rural part of Bursa.

Methods

In this cross-sectional study, study population was composed of students attending primary school in rural part of Bursa. There were 544 students participated for the study, of these 270 students were female and 274 were male. Participants who had two or more headaches in the last 3 months formed the headache group. Afterwards, ID-Migraine™ test was asked to the students in the headache group. Presence of puberty was examined for all the children.

Results

The mean age of the participants were 9.57 ± 2.12 (6-14 years). There were 68 (12.27 %) students suffered from headache of any time in last three months. Migraine-type headache was detected in 12 subjects (2.2%) based on the ID-Migraine™ test. Of the migraine group, six were male (50%) and six were female (50%) as well. Puberty did not affect the frequency of migraine in the study group ($p=0.77$).

Conclusions

Migraine prevalence in the study group was 2.2%. This result is low compared to the previous studies in the literature. Migraine is not affected from puberty. Up to 82% of headaches in children is not migraine type and the etiologies of headaches in the non migraine group should be identified.

P-0369**Hypertension among primary school children at high altitude**

Ali Candar, Hakan Demirci, Yakup Akpınar, Fatih Çiftçi, Hayri Bozkurt

Department of family Medicine, Sevket Yilmaz Training and Research Hospital, Bursa, Turkey

AIM:

Hypertension is an independent risk factor for cardiovascular disease. It is known that essential hypertension begins at a very early age. Recently, there have been reports of an increase in childhood hypertension, which has been attributed to an increase in the prevalence of childhood obesity. It is also known that high altitude is related with high blood pressure. In this study, we aimed to investigate the frequency of asymptomatic hypertension among children living in Buyukorhan district located at 850 meters high.

METHODS:

Two hundred twenty eight children living in Buyukorhan district were enrolled in this study. Blood pressure measurements were performed in two separate visits and average results were calculated. The average blood pressure results were evaluated according to the fourth report criteria. Body mass index (BMI) was calculated as weight/height² (kg/m²). Neck circumference measurements were performed.

RESULTS:

Twenty five children (10.9%) out of 228 were determined to be hypertensive. Among them only four children were male (16%). Gender distribution showed a statistically significant difference ($p=0.004$). There were 10 children diagnosed as pre-hypertensive. BMI was statistically significantly higher ($p=0.007$) among hypertensive children (17.73 ± 3.3) compared to normal subjects (16.09 ± 2.12). The average neck circumference in hypertensive children was 27.4 ± 2.19 cm and it was 26.59 ± 1.73 cm in normal children ($p=0.016$).

CONCLUSIONS:

The frequency of hypertension is high among school-age children living in high altitude in Turkey. There is a female predominance in hypertension. Both BMI and neck circumference were higher in children with hypertension.

²Primary Health Center Centro. Santander. Spain

³Primary Health Gerencia

⁴Primary Health Center Alisal. Santander. Spain

⁵Primary Health Center Los Carmenes. Madrid. Spain

Background & AIM: To establish the profile of accidents among children in one region of Spain.

METHOD: Analysis of the diagnoses of all the emergency cases given by the pediatric emergency service at the most famous hospital in the Autonomous Community, over the period from November 2012 and April 2013. The diagnoses given by the emergency service of children between the ages of 0–15 were analysed.

RESULTS: 4801 accidents were attended to, 19.3% of the total number (24874 pediatric emergencies). If we classify the types of accident, 77.4% were traumas, 12.66% were injuries caused by sharp objects, 4.76% were the extraction of foreign objects, 1.53% were poisonings, 1.48% were injuries caused by domestic pets, 0.93% were burns, and 0.87% were traffic accident injuries. April (21.3%) and March (19.3%) were the months with the highest number of incidents, and Friday (14.9%), Monday (14.58%) and Tuesday (14.35%) were the days with the highest number of incidents, and there were no significant differences when analysing the month or the day when the accident took place. 43% of the accidents involved children under the age of 6. 2.51% of the accidents required hospital admission.

CONCLUSION: Accidents involving children comprise a high percentage of pediatric emergencies. Most cases are traumas. There is not a higher incidence at weekends. Few cases require hospital admission.

The Heterozygote Mutation of Glukose 6 Phospate Dehydrogenase İn The Three Case of Girls That Have Acute Hemolytic Crisis [G6pd Med;563c>T (P.Ser188phe)]

Ebru Yılmaz Keskin¹, Sema Çetin Ayhan², Celeste Bento³, Leticia Ribeiro³

¹Paediatric Haematology and Oncology, Samsun Training and Research Hospital, Samsun, Turkey

²Department of Family Medicine, 19 Mayıs University, Samsun, Turkey

³Haematologia, EPE, Centro Hospitalar de Coimbra, Coimbra, Portugal

INTRODUCTION: Glucose 6-phospate Dehydrogenase (G6PD) deficiency is one of the most frequent form of erythrocyte enzyme disorders. Clinic symptoms are ocured oxidative stress in erythrocyte. The most common symptom of G6PD deficiency is acute haemolytic anaemia. Clinical signs are seen in more hemizygous males because the encoding gene of G6PD is on the X chromosome. The clinical findings in homozygous girls is similar to hemizygotous males in areas of high prevalence. However, clinical signs may be seen in some heterozygous girls depending on the lack of cell population. (Lyon hypothesis)

CASE: Three daughters collected from two unrelated families (aged 2, 5 and 8) applied complaints with abdominal pain, nausea, vomiting, pallor, yellowing of the skin and removing cola-colored urine. Every three children had a history of eating beans two days before of the complaints. It was learnt that these complaints previously appeared two times in aged years of 5 and 8 siblings descended from Iraq. However, it was not though that the reason was the G6PD deficiency because the test of G6PD deficiency was resulted negatively. Normocytic anemia (haemoglobin 7.0, 6.9, 9.4 g/dl), unconjugated hyperbilirubinemia, haemoglobinuria were seen in the laboratory findings of patients who initiated treatment. Direct Coombs test was negative. One times erythrocyte suspension was given to only one patient. In the monitoring, symptoms were improved in all cases. The requested screening test for G6PD deficiency was also negative in the 2-year-old patient. However, the results of molecular analysis in three cases, G6PD Med; 563C>T(p.Ser188Phe) mutation was found to be heterozygous.

Result-DISCUSSION: G6PD deficiency is hereditary transmission based on X sothat the test of G6PD deficiency is usually found to be negative in heterozygoute girls. Quantitative determination of G6PD levels and / or the analysis of mutation may confirm the diagnosis in girls that have typical stories and clinical findings.

Keywords: G6PD deficiency, acute hemolysis

Tablo 1: The laboratory findings of G6PD screening and mutation analysis results for all three girls' cases

	Age (year)	Hb (g/dl)	MCV (fl)	Qualitative G6PD deficiency test	G6PD mutation analysis
Case 1	2	7,0	81,3	Deficiency is not seen.	Heterozygous G6PD Med; 563C>T (p.Ser188Phe)
Case 2	5	6,9*	92,0	Deficiency is not seen.	Heterozygous G6PD Med; 563C>T (p.Ser188Phe)
Case 3	8	9,4	89,3	Deficiency is not seen.	Heterozygous G6PD Med; 563C>T (p.Ser188Phe)

*Patients received transfusions of red blood cell concentrates.

Tablo 2: Intra-erythrocyte G6PD levels in various clinical situations

Clinical case	Sex	Results of screening test	G6PD level	Assessments
Normal	E or K	Normal	8,1	Normal
Normal	E	Abnormal	0,4	G6PD deficiency, stable state

Normal	K	Abnormal	2,1	Heterozygous G6PD deficiency
Normal	K	Normal	4,9	Heterozygous G6PD deficiency
Acute haemolysis	E	Abnormal	2,3	G6PD deficiency in male AHK
Acute haemolysis	K	Normal	7,2	G6PD deficiency in female AHK
Chronic haemolysis	E	Normal	15,5	Unrelated haemolysis with G6PD deficiency
Chronic haemolysis	E	Abnormal	1,4	KNSHA; possible reason is GPDP deficiency

AHK, acute haemolytic crisis; KNSHA, nonsferositik congenital haemolytic anemia

A case of Prepubertal Extragenital Lichen Sclerosus et Atrophicus

Adem Parlak¹, Nehir Parlak², Yusuf Emrah Eyi³, Salim Ozenc⁴

¹Department of Family Medicine, President Guard Regimen, Ankara, Turkey

²Department of Dermatology, Etimesgut Public Hospital, Ankara, Turkey

³Department of Emergency Medicine, President Guard Regimen, Ankara, Turkey

⁴Department of Family Medicine, Diyarbakır Military Hospital, Diyarbakır, Turkey

INTRODUCTION: Lichen sclerosus is a chronic inflammatory dermatosis that results in white plaques with epidermal atrophy and scarring. Lichen sclerosus has both genital and extragenital presentations and also goes by the names lichen sclerosus et atrophicus, balanitis xerotica obliterans and kraurosis vulvae. An increased risk of squamous cell carcinoma may exist in genital disease, but the precise increase in risk and what cofactors (human papillomavirus infection or prior radiotherapy) may be involved are not yet completely defined. Lichen sclerosus et Atrophicus usually affects the genital area of postmenopausal women between ages 40 and 60 years. There are extragenital forms of the disease with a prevalence of 15% to 20%. Such presentations are unusual in children (only 5%-9% of cases) and a challenge to treat. We report herein a 10 year old patient with Lichen Sclerosus et Atrophicus.

CASE: 10-year-old girl presented with a 2 -month history of a asymptomatic, whitish, crinkled, shiny and atrophic plaques surrounded by eritematous halo on her posterior neck, back, abdomen and malleol of left foot. A biopsy revealed lichen sclerosus

CONCLUSION: Inpatient care generally is not required unless for surgery for malignancy or to relieve urinary obstruction is planned. If potent topical steroids are to be used, regular follow-up is required to monitor for the occurrence of steroid atrophy. Monitor female lichen sclerosus patients for any sign of secondary or associated genital malignancy. Extragenital cases require no specific follow-up.

Infantile Acne: report of three cases

Adem Parlak¹, Nehir Parlak², Salim Özenç³, Yusuf Emrah Eyi⁴

¹Department of Family Medicine, President Guard Regiment, Ankara, Turkey

²Department of Dermatology, Etimesgut Public Hospital, Ankara, Turkey

³Department of Family Medicine, Diyarbakır Military Medicine, Diyarbakır, Turkey

⁴Department of Emergency Medicine, President Guard Regiment, Ankara, Turkey

INTRODUCTION: Infantile acne is a rare inflammatory dermatosis that usually starts at the age of 1 to 16 months and may lead to scarring. It persists throughout infancy and occurs mainly on the cheeks and sometimes the forehead and chin, and its morphology includes all typical elements of acne, including comedo, papules, pustules and even cysts. It is more common in boys and is usually mild to moderate in severity. In most children it settles down within a few months.

Case 1: 30-month-old presented to our department with a history of comedones, papules, and pustules on the cheeks since the age of 6 months.

Case 2: A healthy boy presented with an infantile acne with inflammatory nodules, and cysts, ice-pick scars on the cheeks.

Case 3: A 2-year-old boy presented with a 3-month history facial papules on the cheeks. None of the patients had other signs of androgenization or systemic disease. There was no clinical evidence of androgen excess and this was not further investigated.

CONCLUSION: The most common course of treatment for infantile acne is the "wait it out" approach. Since most cases of infantile acne clear up without treatment this is probably what your family physician will recommend, especially if acne is mild. If acne is more severe, or if it's leaving scars, your baby may be prescribed an acne treatment to help get it under control. Actual treatment usually consists of gently cleansing the skin and treating it with topical agents. Only rarely, in very severe cases, are antibiotics or isotretinoin prescribed. Therapy is required for as long as the acne persists. As in adolescent and adult acne, any underlying condition must also be treated.

Treatment differences among several family medical centers in Vilnius in children with acute tonsillitis

Indrė Baužienė¹, Veronika Sruogaitė¹, Kazys Simanauskas¹, Eglė Simanauskienė²

¹Faculty of Medicine, Vilnius University, Lithuania

²Children’s Hospital, Affiliate of Vilnius University Hospital Santariskiu Klinikos

Objective. Acute pharyngotonsillitis is one of the most common infections encountered by pediatricians and general practitioners. The aim of the research is to analyze differences of treatment in children with acute tonsillitis among several family medical centers in Vilnius.

Materials and methods. A retrospective study comprising 300 children in two Vilnius primary health care centers was undertaken to assess the treatment differences among centers. A statistical analysis was done and the significance assessed by a X-square test. The statistical difference was considered significant if the p value was below 0.05.

Results. Both family medical’s center’s doctors as a first-line treatment phenoxymethylpenicillin appointed only 17 (5.66%) and usually both centers selected amoxicillinum 131 (43.6%) and amoxicillinum et acidum clavulanicum 56 (18,66%). Reserve antibiotics atypical agents - as Clarithromycinum center of No. 1 was appointed to three (2%) children in the center of No. 2-18 (12%) of children in the center No.1 Azithromycinum 4 (2.66%), the center no. 2 -9 (6%).

Conclusions. According to our a study general practitioners prescribe antibiotics solely to the symptoms (high fever, increased strangles lymph nodes, sore throat, hyperaemic, hypertrophic tonsils), without making the Strep test or culture of the tonsils, or common blood test, in most cases.

Keywords: acute tonsillitis, treatment differences, general practitioners.

Graves' disease in pediatric age – a therapeutic challenge

Iva Lopes¹, Joana Leça²

¹UCSP de Macedo de Cavaleiros

²USF Terras do Ave

BACKGROUND: Graves' disease is responsible for over 90% of cases of hyperthyroidism in children. It is more common in women, has a peak between 11 and 15 years old and an incidence of 0.1-3 / 100.000 children. Hyperthyroidism is caused by antibodies directed against the TSH receptor, known as TRAb, which mimics the effects of TSH. Virtually 100% of patients present with diffuse goiter. Behavioral changes are more frequent in children than in adults and include irritability, nervousness and decreased performance at school. The diagnosis is based on clinical history and physical examination and it is confirmed through an analytical study. Treatment includes antithyroid drugs, radioactive iodine and / or thyroidectomy.

AIM: To describe a case of relapsing hyperthyroidism in pediatric age.

METHOD: Review of medical records.

Case description: Fourteen years old female, set in a nuclear family stage IV of Duvall, Graffar III. Diagnosed since she was 10 years old with autoimmune thyroiditis with hyperthyroidism. At the time, she presented an analytical study with elevated thyroid hormones, decreased TSH and positive anti-thyroid antibodies. Thyroid ultrasound showed increased thyroid size. Treatment was initiated with metibazol and over 2 years, she was clinically and biochemically euthyroid. The reduction of the drug dosage was progressively made, until discontinuation of therapy. Six months after discontinuation, in a follow-up visit, symptoms like weight loss, insomnia and easy irritability returned. Analytical control was performed, demonstrating the recurrence of hyperthyroidism.

CONCLUSION: Although less common than in adults, thyroid autoimmune diseases also exist in children. It is important that the family physician is properly informed about this condition in order to make an early diagnosis. From the three alternative treatments, none meets all the criteria of safety, effectiveness and establishment of a permanent euthyroidism, which makes this disease difficult to manage.

Keywords: Graves' disease, autoimmune thyroiditis, hyperthyroidism

Relationship of Musculoskeletal System Examination Results with Obesity in Children and Adolescents

Demet Merder Coşkun¹, Arzu Uzuner¹, Mehmet Akman¹, Alp Eren Çelenlioğlu², Özge Keniş Coşkun², Evrim Karadağ Saygı²

¹Marmara University Faculty of Medicine Department of Family Medicine

²Marmara University Faculty of Medicine Department of Physical Medicine and Rehabilitation

BACKGROUND: The relation between childhood obesity and musculoskeletal health problems is not yet fully demonstrated. The aim of this study was to demonstrate the relationship between obesity and musculoskeletal development and functionality on 5-16 years old school children by comparing musculoskeletal examination findings and functionality scores between overweight/obese children and their normal weight peers.

METHOD: This is a descriptive, cross-sectional study. Sample was selected from a previous study carried out between 2013-2014, in which prevalence of obesity among 6-15 years old school children in the province Istanbul Pendik district in Turkey investigated. Informed consents were sent to 3934 parents of children who were assessed as normal weight, overweight and obese in the previous study. They were invited to hospital for a detailed pediatric musculoskeletal examination including posture, gait, balance, muscle strength, range of motion assessment. Turkish version of Pediatric Outcomes Data Collection Instrument "Bedensel İşlevsellik Aracı (BİDA)" was used to assess musculoskeletal functionality. Participants were divided in two groups as overweight/obese and normal weight. Musculoskeletal examination findings and BIDA scores of two groups were compared.

RESULTS: Data of 318 participants was analyzed; 193 (60,7%) were overweight/obese and 125 (39,3%) were normal weight. There was no significant difference within age and gender distribution between two groups. Pes

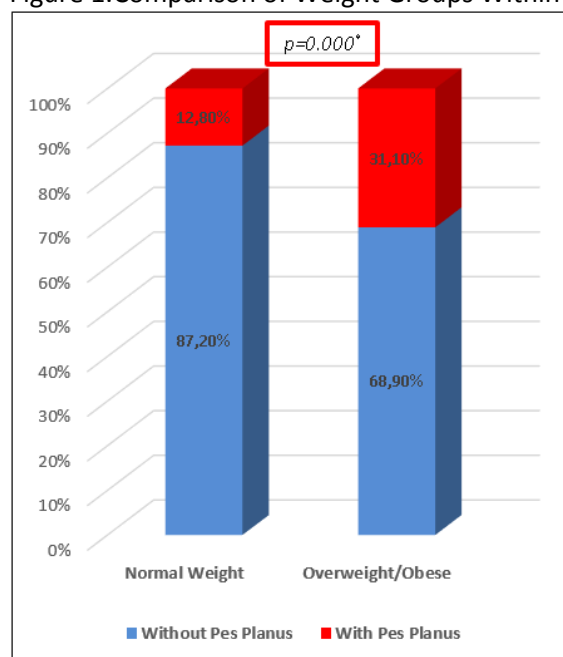

planus was more common, standing time on one leg was shorter, time to complete timed up and go test (TUG) was longer, scores of "happiness" subscale of BIDA was lower and Range of motion (ROM) was decreased in many joints especially on the lower extremity in overweight/obese children than normal weight peers ($p < 0,005$). Body Mass Index (BMI) values showed inverse correlation with both ROM and "happiness" subscale scores ($p < 0,005$). CONCLUSION: Musculoskeletal problems are more common in overweight/obese children than in normal weight children. Interventions to decrease BMI could protect overweight/obese children from severe musculoskeletal diseases.

{I'm fatty, can I use Orlistat?} - An evidence-based revision

Maria Miguel Sá¹, Carla Pina², Juliana Pais²

¹USF Famílias, ACeS Entre Douro e Vouga, Santa Maria da Feira, Portugal

²USF Cuidar, ACeS Entre Douro e Vouga, Santa Maria da Feira, Portugal

Background & Aim

Obesity is an epidemic disease and a public health issue. Child obesity is a rising concern in the medical society especially because of the impact this disease in the future.

The Portuguese government considers this disease to be of serious concern, so much that they have organized a especial task force whose main goal is to invest in the epidemiological investigation related to this issue.

The main treatment is based on the alteration of life style measures such as weight control and exercise programs adapted to children and family routines.

Pharmacological treatment is sometimes seen as the easiest solution and the growing number of drugs launched for weight control can give the illusion of a short term solution. In Europe only one drug is approved for adults, orlistat and there are no drugs approved for children. In the USA orlistat is also approved for children between 12 and 18 years of age.

The goal of this revision is to determine the evidence of efficacy of orlistat in obese teenagers.

Method

Article search during the month of February 2015 using several evidence-based medical databases, in a time period between January 2005 and February 2015, using MeSH terms. For the evidence classification, the OXFORD of Center for evidence-based medicine was used.

Results

In a total of 109 articles identified, 5 were selected, two of which are guidelines, one systematic review and two meta-analysis.

Conclusions

All studies reinforce that the use of pharmacological drugs for weight control in the paediatric population should be of a very exceptional character. The follow-up period of the studies are short which doesn't allow them to be a base for stable recommendations. The guidelines emphasize the specific characteristics that should be present in those individuals that could initiate this kind treatment.

Keywords: obesity, orlistat, adolescent

Systematic Reviews and Meta-Analysis

Reference	Type	Sample	Population	Intervention	Results
Whitlock et al	Systematic Review	7 RCT ↓ 2 about orlistat	Obese individuals between 12 and 18 years (N = 579)	Orlistat (120mg, 3 times a day) Follow-up between 6 and 12 months.	Concludes there is a significant decrease in BMI compared with the institution of behavioral measures. Level 2
Viner et al	Meta-analysis	6 RCT ↓ 2 about orlistat	Obese individuals between 12 and 18 years.	Orlistat (120mg, 3 times a day) Follow-up of 54 weeks .	BMI showed significant decrease compared to placebo. Level 1
Czernichow et al	Meta-analysis	8 RCT ↓ 5 about orlistat	Obese individuals between 10 and 18 years.	Orlistat (120mg, 3 times a day) Follow-up between 6 and 15 months. Drop out: 33, 8%.	This analysis showed no evidence of significant difference in the decrease in BMI, changes in lipid profile or tension profile. High heterogeneity, only one study was subject to MA. Level 2

P-0378**Decision of antibiotics cure in children diagnosed as acute tonsillopharyngitis**

Polat Nerkiz¹, Mehmet Saldır², Kadir Aracı¹

¹Department of family medicine, Gümüşsuyu Asker Hastanesi, İstanbul, Turkey

²Department of pediatrics, Gülhane Military Medical Faculty, Ankara, Turkey

Background&AIM: Antibiotics are used frequently for acute respiratory tract infections. We aimed to reveal the portion of group-A beta hemolytic streptococci (GABHS) causing tonsillopharyngitis upon throat culture applied on children complaining from high fever and sore throat and diagnosed clinically as acute tonsillopharyngitis in this study.

METHOD: Children applying with the complaint of high fever, sore throat and diagnosed as acute tonsillopharyngitis and obtained throat culture were examined. All of the patients were diagnosed as acute tonsillopharyngitis and antibiotic cure was initiated.

RESULTS: 56 children who applied to our medical center were taken to the study. They were between the ages 3-11 and the average age was 6,6. 30 of them were girls and 26 of them were boys. GABHS has been found to be reproduced in 12 (21%) of the patients who have been subjected to throat culture due to acute tonsillopharyngitis diagnosis, whereas normal throat flora was found in 44 (79%) of the patients. It was determined that 79% of the patients had been subjected to unnecessary antibiotic cure.

CONCLUSIONS: Rapid and accurate diagnosis of infectious diseases reduces unnecessary use of antimicrobial therapy. Rapid diagnostic tests suitable for the evaluation of patients in the office or clinics would be helpful for this unsuitable situation.

P-0379**The difficult differential diagnosis of psychogenic asthma in children**

Theodoros Vasilopoulos¹, Georgia Arseni², Dionysios Varthalis², Eirini Trachanatzis², Dimitrios Vasilakis², Nikolaos Kontarakis¹

¹Health center of Ag.Barbara, Herakleio, Crete, Greece

²Venizeleio Gen. Hospital, Herakleio, Crete, Greece

BACKGROUND-AIM: Bronchial asthma is a common disease state of childhood of varying etiology.

Psychopathological conditions may have a duration in time and trigger an asthmatic crisis of varying gravity each time.

The aim of the study was to show that psychogenic asthma exists as a clinical entity in everyday life, but rarely is recognized and treated in its proper dimension.

METHODS: We studied 11 children aged 7-12 years who presented at the medical center with at least four episodes of asthmatic crisis of 48 hours duration, the last two months, treated with one or more anti-asthmatic medications. All children had sudden onset of crises, severe clinical presentation and symptoms. Initially, the common treatment of asthma attack was applied. However, the repeatability of the crisis led to a more cautious history taking. In seven of the eleven children, psychogenic etiology of asthma was suspected. Analytically, two girls, of recently divorced parents, a boy with walking difficulties who suffered the laugh track behavior of peers, two children who repeatedly witnessed episodes of domestic violence, and two girls aged with difficulties in their daily lives due to recent unemployment of both parents. By suspicion of psychogenic etiology of the attacks, common asthma treatment was applied in the emergency department, while social support and psychological treatment was provided by family physician and social services for a period of 3 months.

RESULTS: Gradually, the frequency of asthma attacks in these children was reduced, although no changes in their antiasthmatic therapy was made.

CONCLUSIONS: Psychogenic asthma rarely is rightly approached, resulting in unsuccessful treatment and maintenance at its base. The need for mutual cooperation of the general physician and the family environment is underlined, and the contribution of other social actors as well.

Pediatric Emergency in Sport. A case report

Veronica Parent Mathias¹, Lorea De Unamuno Lumbreras², Irina Yezerska³, Juan Manuel García López¹, Raquel Gomez Bravo⁴

¹Emergency Department Regional Hospital, Málaga, Spain.

²Andalusian Health Public Service, Spain.

³Cantabria Public Health Service, Spain

⁴Semfyc, Spanish Family Medicine Society.

Background

12 years old patient arrive at our health center cause of syncope playing handball at 50m.

During the game he gets hit in the chest by the ball, after that he falls immediately unconscious. At his arrival cardiopulmonary arrest is diagnosed, and we start CPR, we send someone to search the Automated external defibrillator (AED). Resuscitation was initiated and the defibrillator provides 2 defibrillations. He was transferred to the hospital. The electrocardiogram on admission shows Ventricular Fibrillation so he gets the third defibrillation. It appears sinus rhythm. He gets hemodynamically stable without arrhythmias. Color echocardiogram shows no cardiac structural alterations and ECG-Holter 24 h was normal too.

Results: Sudden death due to cardiac shock is caused by a direct hit to the chest, in the absence of underlying cardiovascular disease, and it is an event known as commotio cordis, one of the most frequent causes of sudden death in young athletes. In USA most victims are men (95%) and ethnic "white" (78%). 50% of events take place in Sports in the high competition. It must be a hit in the chest by a blunt object, a ball or body contact with another player, directly on the heart, and it has to take place in the electrically vulnerable period of the cardiac cycle (rising part of the T wave, just before its peak).

The treatment is defibrillation. There is no evidence that survivors of commotio cordis event present new high risk of arrhythmic events and secondary prevention is not indicated.

CONCLUSIONS (and applicability for family medicine)

Family physicians work in health care centers and they can be near sports centres. They must have an AED. They can save lives like in our case.

When everything seemed to be ok... - A clinical case of adolescent idiopathic scoliosis

Vera Pires Da Silva, Ana Luísa Gomes

USF Ramada, Loures, Portugal

Background and AIM:

Pediatric scoliosis is a relatively uncommon condition, defined as a structural alteration of the spine with a lateral curvature greater than 10°. It includes a broad range of conditions with or without clear etiology. Adolescent idiopathic scoliosis (AIS) is the most common form (approximately 3%) but only 10% require treatment and it is uncommon to need more than intermittent clinical and radiographic observation. We present a case of AIS with an extremely sudden curvature progression causing a marked deformity and requiring surgical treatment.

METHOD:

Data was gathered during an office visit with the adolescent and her mother; analysis of patient's clinical records including medical history, physical examination, diagnostic procedures, treatment and evolution; and discussion of the case with the orthopedic surgeon. A literature review regarding AIS was also performed.

RESULTS:

Thirteen year old girl, normal birth and development history, Tanner Stage III, no menarche, no relevant family history. Scheduled by her Family Physician (FP) for routine evaluation considering that her last visit was over 2 years ago. Without any complaints. On physical examination marked asymmetry was detected of shoulder, scapula and posterior thoracic cage; Adams forward

bend test showed marked rib prominence; no leg length discrepancy. Spine X-ray revealed scoliosis with Cobb angle greater than 70°. Referred to Orthopedic Surgery where, due to severe curvature, was submitted to surgery with good outcome and evolution. Presently maintains regular FP follow-up.

CONCLUSION:

This case reinforces the importance of FP's evaluation on regular basis. Early spine deformity detection might allow a non-operative management of scoliosis. FP need to maintain high suspicion and provide continued monitoring, particularly during adolescence's growth spurts when scoliosis curves have the highest risk for progression.

Hypercholesterolemia and statins in children: what impact on LDL cholesterol?

Juliana Pais¹, Maria Miguel Sá², Carla Pina¹

¹USF Cuidar, ACeS Entre Douro e Vouga, Santa Maria da Feira, Portugal

²USF Famílias, ACeS Entre Douro e Vouga, Santa Maria da Feira, Portugal

Background & aim

Hypercholesterolemia is a common disease in adults and rising in children. These changes are usually associated with cardiovascular events.

Various studies show that complications are reduced if lifelong hypolipidemic measures are taken prematurely.

The aim of this revision is to determine the efficacy of statins on reduced LDL cholesterol in pediatric patients compared with placebo or other pharmacological therapies.

Method

Comprehensive searches had been conducted in March 2015 on several evidence-based medical databases, between January 2005 and February 2015, using MeSH Terms. For the evidence classification was used the OXFORD.

Results

Were identified 19 articles and selected 8. Those were three guidelines, three systematic reviews and two meta-analyses.

Conclusions

All the studies incorporated in the revision are consistent with the fact of statins be are well tolerated, safe and efficacious in short-term, although long-term safety remains unclear.

Primordial prevention, which includes counseling diet and lifestyle modifications (not smoking and regular physical activity) are the most important component of the treatment. However many studies support

pharmacologic treatment, for children (between ages of 8 and 10, depending on studies) at higher cardiovascular risk, with statins.

The most part of the studies only included children with familial hypercholesterolemia and so is difficult to extrapolate to another population. There is no evidence of efficacy on prevention of morbidity or mortality related to adult-onset cardiovascular disease.

Large long-term randomized controlled trials are needed to establish the long-term safety issues of statins in this population.

Keywords: Adolescent, child, preschool, dyslipidemia, Hydroxymethylglutaryl-CoA Reductase Inhibitors

Systematic review

Study	Type of Study	Sample	Population	Intervention	Results	Level Evidence
Y. Leberthal et al (2010) Archives of Disease in Childhood	RS	7 RCT n= 884	Family Hipercholesterolemia (FH) patients aged 8-18 years	- statins vs. placebo - 28 week intervention	Statins have impact on the reduction of total and LDL Cholesterol	1
A. Vuorio et al (2014) The Cochrane Collaboration	RS	8 RCT n= 1074	FH patients aged 8-18 years	- statins vs. placebo - Diet 6 week- 2 years intervention	- Statins reduce LDL concentrations averaging 23-40% - We need to long-term studies in this age group.	2

Meta-analysis

Pubertal development in adolescence - Comparative analysis of self-assessment and medical evaluation among adolescents at the University Hospital of Brasilia

Marilucia Rocha De Almeida PICANCO, Wander Alysson Santos De Carvalho, Tiago Artur Lyra Leite, Luciana Nakanishi
Universidade de Brasília - Brasil

Background and AIM: The study aimed to perform the analysis of the self-assessment of sexual maturation performed by adolescents in clinical consultation, comparing it to the objective medical evaluation. METHOD: This is a cross-sectional and double-blind study, carried with adolescents in the Health clinic of the University Hospital of Brasilia. RESULTS: It has been shown by the study that adolescents know little about their body and there is no global agreement between self-assessment and medical assessment of sexual maturation stages with percentage of 31.58%. It was found a frequent presence of pubic hair removal in adolescents of both sexes, considering of 21.05% in males and 78.95% in females. In the presence of trichotomy, there was an agreement of self-assessment and objective assessment regarding the pubic hair of 42.11%, and in the absence the agreement was of 57.89%. CONCLUSIONS: It is suggested that self-assessment of sexual maturation is unreliable and that teenagers do not know their body. Moreover, the high rate of pubic hair removal in adolescents can lead to a confusing factor when assessing the degree of sexual maturation considering the pubic hair factor.
Keywords: Adolescence, sexual maturation, self-assessment

Percentage of agreement in both sexes, taking into account the pubic hair in the presence and absence of trichotomy

Assessment of nutritional status in children and adolescents in Malvinas Argentinas District, Buenos Aires, Argentina

Juan Emilio Casabella¹, Favio Flores², Zara Paiva³

¹Municipio de Malvinas Argentinas, Buenos Aires

²Municipio de Malvinas Argentinas, Buenos Aires

³Municipio de Malvinas Argentinas, Buenos Aires

Introduction and aim.

Overweight is an increasingly condition in childrens and teenagers in primary care consultations, in Malvinas Argentinas District, however health teams based on experience from previous years prioritized the investigation of malnourished children. It is the aim of this study to describe the prevalence of both malnutrition and obesity in children of this county.

.Primary OBJECTIVE:

⊗ To assess the nutritional status of schoolchildren in differents primary care units of Malvinas Argentinas district.

To carry on medical interventions if necessary.

Secondary OBJECTIVES:

⊗ Assess fullfilment of immunization schedule and initiate recovery scheme vaccine if necessary.

⊗ Assess Visual Acuity.

⊗ Detect the presence of caries.

METHODS:

Observational, descriptive cross-sectional study conducted in 20 functional units of the Municipality of Malvinas Argentinas, during and March 2014 during February.

3002 children between 2 and 20 years were evaluated.

Data were obtained from HC made in Aptos Physical Operational School. The Anthropometric Tables Z-score WHO were used for age and sex, evaluating weight / age, height / age and body mass index (BMI).

RESULTS:

3002 patients were evaluated, of which 55% (n = 1651) had adequate weight, 36% (n = 1081) Overweight / Obesity and 9% (n = 271) were underweight / malnourished.

The highest percentage of malnutrition was in the age range of 2-5 years.

The highest percentage of overweight / obesity was detected in the age range of 6-11 years.

The percentage of children with caries was similar in the 3 groups, overweight and obesity: 59%, right Weight: 55%, Low weight, Malnutrition: 62%.

CONCLUSIONS:

Among the data evaluated in our town we observed higher prevalence of overweight / obesity in relation to underweight children.

Caries prevalence was similar in the three groups evaluated.

Almost all of the patients tested had full schedule of vaccines for age.

Keywords: obesity, malnutrition, overweight, vaccination, primary care intervention

DISTRIBUTION OF PATIENTS BY AGE AND GENDER

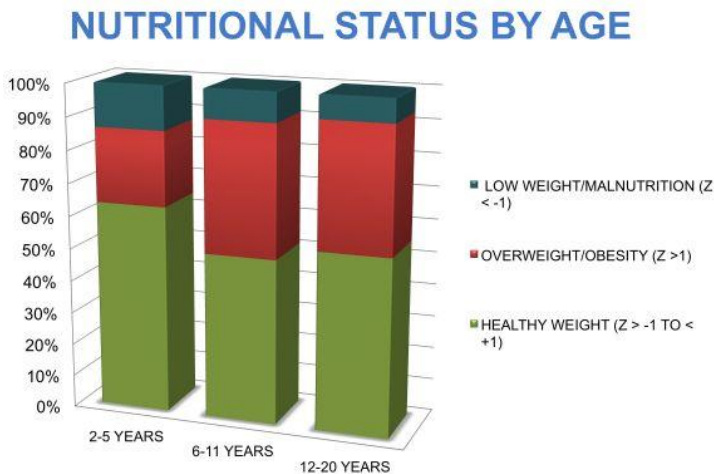

3002 patients were evaluated

OVERALL NUTRITIONAL STATUS

55% (n = 1651) had healthy weight, 36% (n = 1081) Overweight / Obesity and 9% (n = 270) were underweight / malnourished.

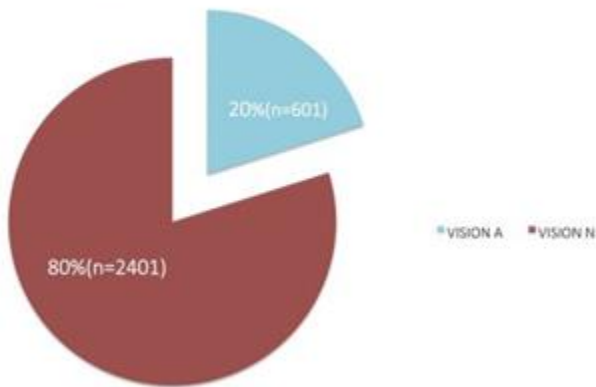

NUTRITIONAL STATUS BY AGE

The highest percentage of malnutrition was in the age range of 2-5 years. The highest percentage of overweight / obesity was detected in the age range of 6-11 years.

VISUAL ACUITY

VISUAL ACUITY EXAM

Regarding to visual acuity, 80%(n=2401) had normal visual acuity and 20% (n=601) had alteration in visual acuity.

DENTAL EXAM

In dental examination, 57% (n=1711) of children and adolescents had caries, while 43%(n=1291) did not.

VACCINATION

95%(n=2852) of children and adolescents had age appropriate vaccination/immunization schedule, 5%(n=150) of these did not.

Prevalence of Hypertension in Patients referred to the General Pediatric Outpatient Clinics in Ege University Faculty of Medicine Hospital

Havva Polatci¹, Guldane Koturoglu², Asli Aslan², Zafer Kurugol², Huseyin Can¹

¹Department of Family Medicine Clinic, Izmir Katip Celebi University Atatürk Training and Research Hospital, Izmir, Turkey

²Department of Child and Diseases Clinic, Ege University, Izmir, Turkey

AIM: This study was performed in order to investigate the prevalence of hypertension among children between 3-18 years of age referred to Ege University Faculty of Medicine Hospital Child Health and Diseases Outpatient Clinics for any reason.

MATERIAL- METHOD: 488 children between 3-18 years of age referred to General Pediatric Outpatient Clinics between May - July 2014 were included in this study. Data were achieved via questionnaires by face to face interview technique. In the questionnaires, the age and sex of the patients, their complaints, presence of any chronic disease, history of drug use, family history of hypertension were questioned. Patients' measures of weight, height, body mass indices and blood pressure were performed by a detailed physical examination. **RESULTS:** 258 of patients (52.9%) were male, 230 of them (47.1%) were female. Mean age was 9.44 ± 4.22 years. Normotension was determined in 83.4% of the patients, prehypertension was determined in 15%, stage 1 hypertension was determined in 1.2% and stage 2 hypertension was determined in 0.4% of the patients. In 47.5% of the patients diagnosed with prehypertension and hypertension, obesity was determined. In the evaluation of family history of hypertension; 34,3% of normotensive patients, 36,9% of prehypertensive patients, 100% of stage 1 hypertension patients and 50% of stage 2 hypertension patients had a positive family history. In 37,5% of patients diagnosed with hypertension had a history of drug use. The most commonly used drug was methylphenidate.

CONCLUSION: Hypertension is a frequent clinical situation that is detected during childhood and may lead to serious mortality and morbidity. Blood pressure measurements as a part of routine physical examination especially in children older than 3 years of age and identification and treatment of these patients are life saving.

P-0386

Assessment Of Depression And Social Phobia Of Obese And Overweight Adolescents

Sara Akıcı¹, Dilek Toprak Evcik¹, Ibrahim Hakkı Aktan²

¹Family Medicine Clinic, Şişli Hamidiye Etfal Training and Research Hospital, Istanbul, Turkey

²Pediatric Clinic, Şişli Hamidiye Etfal Training and Research Hospital, Istanbul, Turkey

AIM: In this research, we aimed to investigate the relationship between adolescents' BMI with depression and social phobia.

MATERIALS-METHOD: This study is a case-control study which was conducted among 10-17 age adolescents in Şişli Hamidiye Etfal Training and Research Hospital General Pediatric Polyclinic. The research conducted between April 2014-October 2014. After investigating for sociodemographic features, Child Depression Inventory (CDI) and Çapa Social Phobia Scale for Child and Adolescent (CSPSCA) were applied. Every adolescent's length-weight measurement performed and BMI was calculated. Obese- overweight adolescents were defined as "case group" and normal weighted adolescents were defined as "control group".

RESULTS: In this study, out of 183 cases, aged between 10-17, 91 were male, 92 were female; 90 were normal weighted, 93 were obese-overweighted. Both groups were similar in the male-female ratio. Obese-overweight group's school scores were higher, they were attending school activities less, having breakfast more regularly, was doing less physical activity, were usually only child in the family, their parents had more chronic diseases, they perceived their families' financial situation better than it is compared to normal weight group ($p < 0.05$). Obese-overweight adolescent's mothers and fathers were more obese ($p = 0,016$ and $p = 0,0001$ respectively). There was no significant difference between the groups about CDI-CSPSCA scores ($p = 0,665$; $p = 0,100$). In normal weighted group there was a positive linear and intermediate level correlation between CDI-CSPSCA scores, but in Obese-overweighted adolescent group there was no correlation like that. Obese-overweight girls had higher scores of CDI than normal weighted girls.

Obese-overweight adolescents who didn't do physical activity regularly; the CDI scores ($p = 0,070$) and the CSPSCA scores were found to be higher ($p = 0,067$). In both groups, there was a significant negative weak correlation between family economic status and CSPSCA scores ($p_{\text{case group}} = 0,009$, $p_{\text{control group}} = 0,013$).

CONCLUSION: This study showed that parents' obesity and childhood obesity highly correlated. Adolescents' obesity is associated with social phobia and depression severity. Necessary measures should be taken to prevent possible psychological problems of over-weighted adolescents.

First year of Growth and development of children of primiparous teenage mothers - comparative study with children of adult mothers

Marilucia Rocha De Almeida PICANCO, Barbara Trapp, Juliana Carolina Martins Vissoci, Luciana Rodrigues Costa, Juliane Marchese

Universidade de Brasília - Brasil

Background and AIM: This study aimed to analyze the growth of children of teenage mothers (<19 years) in their first pregnancy, accompanied in the Pediatrics service in the University Hospital of the University of Brasilia - Brazil, during their first year of life compared with data from children of adult mothers (20-34 years). **METHOD:** The data were obtained by a standard questionnaire applied and collected longitudinally during routine pediatric consultations. We used the SPSS software and the chi-square test for significance analysis. 89 adolescent mothers in their first pregnancy / babies were analyzed, and 92 dyads of non-teenager, from 20 to 34 years, mothers / babies. **RESULTS:** The results showed that the children of adolescent mothers showed no significant differences regarding birth weight and length to the pattern of the children of adult mothers during their first year.

CONCLUSIONS: Adolescents mothers weaned their babies earlier and their babies grew up with lower monthly weight gain, but without statistical significance. Regarding the neuro psychomotor development, infants showed delays in some important marks only reaching them after intervention. Considering the social adaptability, they

showed more sleep disorders and more difficulty to establish bonds, when compared with the children of primiparous adult mothers.

Metabolic syndrome among adolescents treated at the University Hospital – Brasilia/DF: A comparative study using two diagnostic criteria: IDF and NCEP-ATPIII

Marilucia Rocha De Almeida PICANCO, Wander Alysson Santos De Carvalho, Tiago Artur Lyra Leite, Luciana Nakanishi
Universidade de Brasília - Brasil

INTRODUCTION: The number of pregnant teenagers is increasing in the country and particularly in the Federal District. Teenage pregnancy is today, in Brazil, the eighth leading cause of death among adolescents aged 10-19 years old and childbirth is the leading cause of hospitalization in the lowest range of 15 years. The project consists of the monitoring of primiparous adolescent mothers and their babies during the first year of life of their children. Its main objectives are: to identify their social and demographic profile; to welcome mothers in the group work; to follow the growth and development of children during the first year of their life by promoting comprehensive care to the baby and teenage mothers, while also carrying out the objective to reduce the chance of a second pregnancy by conducting them to the Family Planning service. **METHOD:** The first contact with teenage mothers occurs in the maternity ward, where a standard questionnaire with questions about social and obstetrical aspects of these mothers and their children is applied, for the preparation of a database on the profile of this group. **RESULTS:** They are, then, forwarded to the pediatric service in the supervision of a Professor, on Wednesdays and Fridays in the morning, to carry out the medical appointments for their children. **CONCLUSIONS:** On the same day of the appointments an educational meeting is carried out in which there is discussion about contraception, STDs, general baby care, breastfeeding, strengthening the mother-infant bond, postpartum depression, and the prevention of a second pregnancy. These mothers are also forwarded to meetings in the area of Family Planning and other specialties according to their needs.

³USF Araceti

The family doctor's knowledge about the ideal age to refer children for Pediatric Surgery: a quality evaluation

Background

The referral of children to Pediatric Surgery, although infrequent, needs exceptional care by the family doctor. The referral in a timely manner increases the surgery's degree of success and decreases the potential complications for the affected child.

Aim

This work aims to evaluate and increase the knowledge of Family Doctors and interns of family medicine about children's ideal age of referral for Pediatric Surgery.

Method

The doctors in a Healthcare Unit filled an anonymous and voluntary survey, consisting of 12 questions, about the ideal age to refer children for Pediatric Surgery in December 2014. A brief clinical session was then performed explaining the authors choice of correct answer based on national guidelines and textbooks consulted. A second anonymous and voluntary survey was submitted to the same doctors in March 2015. The results were then analysed to evaluate if the clinical session increased the knowledge, measured by the percentage of correct answers to both surveys.

Results

The first survey was completed by a total of 26 doctors. There were a total of 12 questions made and the correct answers vary between 19% and 96%, with an average of 52% of correct answers. In the second survey answered 18 doctors and the correct answers vary between 23% and 100%, with an average of 58% correct answers.

Conclusions

When evaluating the results obtained we can conclude that the clinical session had a positive, although slight, impact on the knowledge of doctors about children's ideal age of referral for Pediatric Surgery. The results show an ample margin of improvement in the knowledge of family doctors about pediatric pathology.

Case report: Sometimes is more than lack of education

Erica Mendes

UCSP de Tarouca, ACES Douro Sul, Tarouca, Portugal

BACKGROUND & AIM: Autism spectrum disorder (ASD) is characterized by persistent deficits in social communication and interaction, and by present of repetitive and restricted behaviors, interests and activities. It includes a broad variety of symptoms, skills and levels of disability. Normally it is diagnosed in the two first years of life. It has a prevalence of approximately 1% of the children and is four times more prevalent in males than females.

METHOD: To make this report we used the clinical process complemented with a bibliographical research.

RESULTS: Male child, 9 years old. When he was 4 years and 9 months old, he began to show behavioral change that included: isolation, strange behaviors, excessive activity, attention disorder and aggressive behavior with pairs. After being presented to the family doctor and pediatrician was referenced to the child and adolescent psychiatry. He was diagnosed with attention deficit hyperactivity disorder and was medicated with methylphenidate at the age of 5. After a mild improvement, at the age of 7, he became more isolated and demonstrated the following: inability to relate to others and didn't make eye contact, inappropriate playing with toys, inappropriate laughing and strange attachment with objects. After reevaluation by the child psychiatry, was diagnosed with ASD (Asperger syndrome), the prescription was adjusted and started specialized therapies.

CONCLUSIONS: This case demonstrates that the differential diagnosis of ASD can be difficult. It is essential to make an early diagnosis, in order to provide the best treatment and support to these children and to improve their development and prognosis. The role of family practitioner is crucial to provide an early diagnosis and adequate follow-up. It is also presented the importance of the relations between the society, family, medical specialties and patient, where the family practitioner plays a central role.

Primary Health Care approach of iron deficiency anemia in pediatric age: performance protocol

Helena Ribeiro¹, Cláudia Neto², Fernando Carvalho¹

¹USF Novos Rumos, ACES Alto Ave, Vizela, Portugal

²Pediatric Department, Centro Hospitalar do Alto Ave, Guimarães, Portugal

BACKGROUND: Anemia is an important public health problem, particularly in more susceptible groups such as pregnant women and children. The primary cause of anemia is iron deficiency, that may arise in many situations such as dietary errors, iron requirement increase, bleeding and intestinal malabsorption. In pediatric age, iron deficiency anemia has been associated with delayed physical growth and psychomotor impairment.

AIM: To review the literature regarding the approach to iron deficiency anemia in pediatric age in Primary Health Care.

METHOD: Articles research in Medline/Pubmed, guidelines and specific books in Portuguese or English, using the Mesh terms: anemia, iron deficiency.

RESULTS: The presumed diagnosis of iron deficiency anemia can be made through clinical history, physical examination and complete blood count with red blood cell indices (RBC indices). In patients where there is doubt regarding anemia's etiology, is recommended evaluation of iron parameters such as iron levels, ferritin and transferrin saturation. After beginning iron supplementation, the patient should be reevaluated in one month to verify if values of hemoglobin rise at least 1mg/dL. If the response is positive, the treatment should be maintain in order to replenish iron stores.

CONCLUSION: The iron deficiency anemia is a common condition that can be treated and oriented in Primary Health Care. The General Practitioner (GP) should be able to detect warning signs or other possible anemia etiologies that should motivate referral of the patient to the hospital. Other major role of GP is the prevention of anemia through iron supplementation according to age, type of feeding and physiological needs.

Keywords: anemia, iron deficiency, pediatric age

Primary Health Care approach of iron deficiency anemia in pediatric age: diagnosis

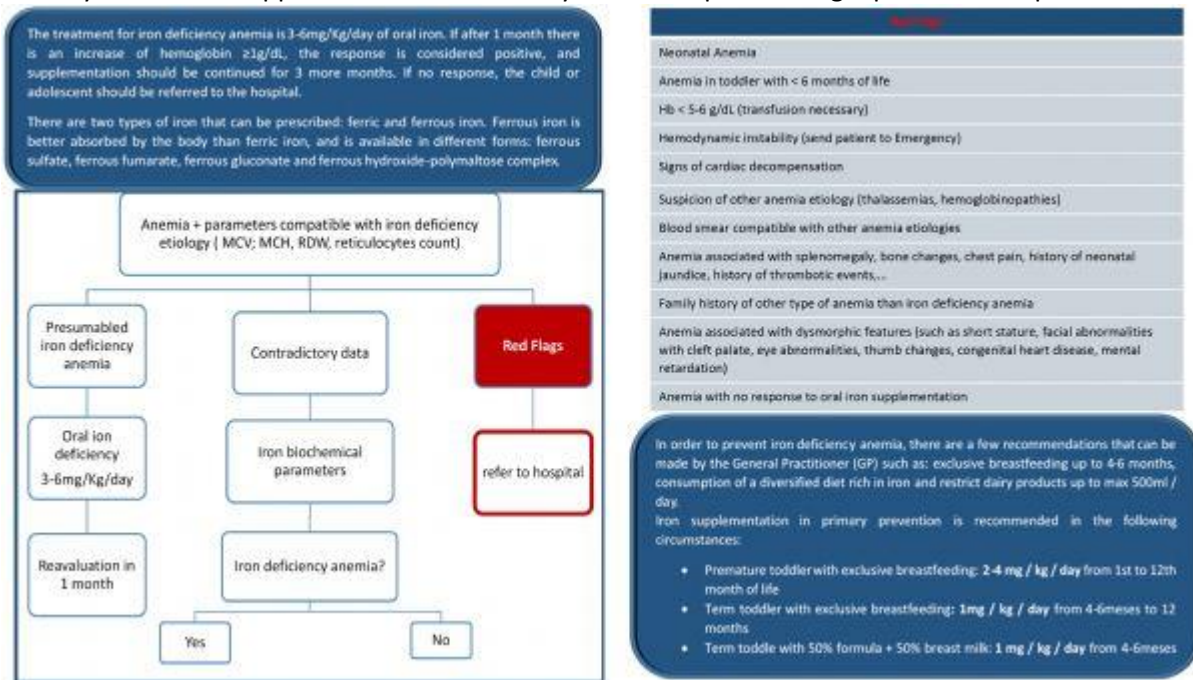

An adequate clinical history and physical examination are essential in the initial management of iron deficiency anemia.

Clinical history	<p>Personal Background Low birth weight; prematurity Breastfeeding after 4-6 months without iron supplementation Gynecological history Pathological history: inflammatory or infectious condition</p> <p>Toxic and Drugs History of exposure to lead; well water consumption (nitrates, parasites); drugs consumption.</p> <p>Family History Haematological disorders in the family Inflammatory bowel disease; polyps; cancer; jaundice; gallstones; splenomegaly.</p> <p>Diet Consumption of meat and vegetables; dairy products.</p> <p>Symptoms Frequently asymptomatic Muscle fatigue; apathy; irritability; lower exercise tolerance Suggestive of hemolysis: choluria, acholia, jaundice Blood loss</p>
Physical examination	Pale skin, Skin atrophy, koilonychia, angular stomatitis, glossitis, oesophageal and pharyngeal webs, Tachycardia and cardiac failure (in severe anaemia).

Although the history and physical examination can be helpful, the diagnosis of anemia and the type of anemia is achieved through laboratory parameters. In most cases for the diagnosis of iron anemia deficiency the parameters necessary are: hemoglobin concentration, mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH), red cell distribution width (RDW), reticulocytes count and reticulocyte hemoglobin concentration. When in doubt, other biochemical parameters may be evaluated such as serum iron (SI), total iron binding capacity (TIBC), transferrin saturation (TS), free erythrocyte protoporphyrin (Epp) and serum ferritin (SF). Through this evaluation it is possible to distinguish iron deficiency anemia from another type of anemia that may need immediate referral to hospital care.

Parameters	Iron Deficiency Anemia	β-Thalassemia	α-Thalassemia	Inflammatory Chronic Disease
Erythrocytes	↓	N/↑	N	N
MCV	↓	↓	↓	N/↓
RDW	↑	N	N	N
Reticulocyte	↓	↓	↓	↓
Mean Iron	>13	<13	N/A	N/A
Ferritin	↓	N	N	N/↑
Transferrin saturation	↓	N	N	↓
Hemoglobin electrophoresis	Normal	Increased (>3.5%)	HbA2 ↓ HbF ↑ Disease (H y chains)	HbE ↑ Normal
Blood smear	microcytotic	anisocytotic		
Response to iron treatment	Improvement	No improvement	No improvement	No improvement
Treatment	Iron supplementation	Parents evaluation, genetic counseling, periodic planning pregnancies	HbE ↑ Disease splenectomy	Blood

Vaccine against "Neisseria meningitidis" serogroup B: what is the evidence?

Helena Ribeiro¹, Nuno Namora², Teresa Martins¹, Maria João Abreu²

¹USF Novos Rumos, ACES Alto Ave, Vizela, Portugal

²USF DuoVida, ACES Alto Ave, Guimarães, Portugal

BACKGROUND: Currently, "Neisseria meningitidis" serogroup B is the main responsible for invasive meningococcal disease and a new vaccine was developed against this bacterium.

AIM: The aim of this study was to review the scientific evidence on the immunogenicity, safety and reactogenicity of the vaccine against serogroup B (4CMenB or Bexsero®) in children.

METHOD: Literature search in the National Guideline Clearinghouse, Guidelines Finder, The Cochrane Library and PubMed using the terms "meningococcal B vaccines" and "serogroup B". Levels of evidence and strength of recommendation were assigned according to the Strength of Recommendation Taxonomy scale (SORT) from the American Family Physician.

RESULTS: Two Randomized Controlled Trials (RCT) and one Systematic Review (SR) were included. The studies considered the vaccine 4CMenB safe but more reactogenic when co-administered with other vaccines. Four studies concluded that the vaccine was immunogenicity in infants with 2 months of age. It was also considered immunogenic in infants with 6 months (one RCT), children (one RCT) and adolescents (one RCT). In the two RCTs, there was a decreased immune response in infants with three years of age who were vaccinated in the 1st year of life.

Discussion and CONCLUSION: In the published studies, the vaccine was considered safe (SORT A), more reactogenic when co-administered with other vaccines (SORT A) without affecting the immunogenicity of these (SORT A). The vaccine was considered immunogenic in infants with 2 months of age (SORT A), infants with 6 months (SORT B), children (SORT B) and adolescents (SORT B). However further studies are needed to evaluate the effectiveness, duration of immunity, long-term safety and cost-effectiveness for the Portuguese reality.

"{" Evaluation of Adenovirus and Rotavirus Prevalence Among Inpatients at Child Infections Clinic Diagnosed as Gastroenteritis "}"

Cansu Öztürk, Aycan Topaloğlu, Dilek Toprak

Şişli Hamidiye Etfal Training and Research Hospital Family Medicine Clinics, Istanbul, Turkey

AIM: Acute gastroenteritis in children is the second important cause of infectious morbidity after the respiratory infections. Rotavirus and adenovirus are two of the most important infectious causes of childhood gastroenteritis. The purpose of this study is to determine the frequency of rotavirus and adenovirus of inpatient children who pre-diagnosed as acute gastroenteritis in child infectious diseases clinic.

METHOD: Rotavirus and adenovirus 40/41 antigens were investigated by immunochromatographic method in stool samples of 96 child inpatients admitted at our children infectious disease clinic in hospital with the diagnosis of acute gastroenteritis between June 2013-June 2014.

RESULTS: There are 96 patients of which %55,2 was male and %44,8 was female. Average age was 2.61 ± 2.90 (0-15). Rotavirus was positive in 33,3% (n=32) and adenovirus was positive in 4,2% (n=4) stool samples. 57% of patients having positive Rotavirus antigen were male, 75% of patients having positive adenovirus antigen were male. Patients of Rotavirus antigen positivity 57%, patients of adenovirus antigen positivity was 75% It has been observed that both rotavirus and adenovirus antigen at stool specimens are more common at boys. Meaningful relation is not observed between the genders having positive Adenovirus and Rotavirus $p=0,885$, $p=0,416$. It is observed that positive Rotavirus ratio is %38,5 and Positive Adenovirus ratio % 4,6 for the ages below 2 years old. There was no significant relationship between virus positivity and age.

CONCLUSIONS: Rotaviruses is the most common agent in childhood acute gastroenteritis. The detection of viral factors at acute gastroenteritis is important to prevent inappropriate antibacterial and antiparasitic drug usage. Detection of enteric viruses is important for patients since viral gastroenteritis may cause serious complications.

Tonsillectomy, Adenoidectomy and Adenotonsillectomy Rates in School-aged Children: Relative Contributions of Socio-demographic and Clinical Features

Yusuf Cetin Doganer¹, James Rohrer², Umit Aydogan³, Mckennan Thurston², Kenan Saglam⁴

¹Department of Family Medicine, Turkish Military Academy, Primary Care Examination Center, Ankara, Turkey

²Department of Family Medicine, Mayo Clinic, Rochester, Minnesota, USA

³Department of Family Medicine, Gulhane Military Medical Faculty, Ankara, Turkey

⁴Department of Internal Medicine, Gulhane Military Medical Faculty, Ankara, Turkey

Background & AIM: The present study sought to investigate the frequencies of tonsillectomy, adenoidectomy and both adenotonsillectomy (T&A) among 6-12 year old children. In addition, we tried to find out the predictors associated with these previous upper respiratory tract (URT) surgeries.

METHOD: This cross-sectional study consisted of 1900 children educated in 3 different elementary schools in Ankara, Turkey. Data about demographics and health conditions were obtained from survey questionnaires completed by parents.

RESULTS: Of the 1900 children, 15 children (0.8%) previously underwent tonsillectomy, 43 children (2.3%) had adenoidectomy and 80 children (4.2%) had T&A surgical histories. Multiple logistic regression analysis revealed that older students compared to younger ones [Odds Ratio (OR) = 1.15, $p=0.011$], and those who had parent-reported apnea compared to subjects without apnea were more likely to have URT surgery histories [OR=2.34, $p=0.001$]. Those children with surgery histories were more likely to have fathers with a higher educational level [medium level: OR=2.07, $p=0.012$; high level: OR=2.79, $p=0.001$ vs. low level] and the subjects had greater BMI percentiles [overweight: OR=1.71, $p=0.036$; obesity: OR=2.32, $p=0.003$ vs. healthy weight]. Children who had 1-2 URT infections per year [OR=0.47, $p=0.019$] had less probability of URT surgery histories, whereas those children

with AOM ≥ 3 times per year [OR=2.52, p=0.003] had more probability of URT surgery history.

CONCLUSIONS: We conclude that a reasonable explanation for higher rates of URT surgery among children with a high level of paternal education may originate from their awareness about URT associated diseases and possibly due to the ease of access to health care services.

Alternated or combined use of paracetamol and ibuprofen in the treatment of fever in children: There's evidence?

Simão Costa Martins¹, Joana Andrade Barros², Lisete Aires Silva², Sabrina Pedone², Sonia Marcelo²

¹USF Hygeia, Lixa, Portugal

²USF Terras de Souza, Paredes, Portugal

Background & AIM: Fever is a very common reason for consultation in children. In general, this entity does not last for long, is benign and should be understood as an adaptive body sign. Despite being effective, safe and cost-effective, there are few studies that clearly recommend alternate / combined use of the commonly used antipyretics. The aim of this study was to review the recommendations and gather existing evidence into practice/use of alternate and combined therapy of paracetamol and ibuprofen in the treatment of fever in children.

METHOD: There were researched clinical guideline standards (NOC), systematic reviews, meta-analyzes and randomized controlled trials (RCT), from Medline / Pubmed, Clinical Evidence, Evidence Based Medicine Online, National Guideline Clearinghouse, National Library of Guidelines, Canadian Medical Association Practice Guidelines, Cochrane Library, DARE, and Bandolier Index of Portuguese Medical Journals, from the last 10 years, in Portuguese and English, using the MeSH terms: "Acetaminophen / administration and dosage ", " Acetaminophen / therapeutic use ", " Ibuprofen / administration and dosage ", " Ibuprofen / therapeutic use ", " Fever ". To assess the level of evidence and strength of recommendation assignment, Strength of Recommendation Taxonomy of the American Academy of Family Physicians was used.

RESULTS: There were found 299 articles, which 18 selected articles: 5 systematic reviews, 10 randomized controlled trials and 3 guidelines.

The randomized controlled trials refers that it seems to exist an upper effect in fever reduction in children, with alternate or combined antipyretic therapy, however, the included systematic reviews and guidelines results, shows that this evidence is not strong enough to recommend this practice.

CONCLUSIONS: Combined and alternating therapy seems to reduce fever in children, more consistently, especially in the initial phase. However, more studies are needed to evaluate the safety / toxicity of these regimens in the pediatric population.

Keywords: Acetaminophen; Ibuprofen; Fever

Table 1

Authors	Year	Population	Conclusions	EL
Wong T, et al. ¹³	2013	Children with fever	There is some evidence alternated and combined antipyretic therapy is more effective than monotherapy in temperature reduction; There are still doubts as to the benefit from its use	1
Pereira GL, et al. ⁵	2012	Children ≤ 12 years	Downward trend in average temperatures; There is not enough evidence to say that this practice is more effective than monotherapy	1
Purssell E. ¹⁴	2011	Crianças com febre	Short evidence in the combined therapy; There is no increased toxicity despite this studies have small populations; This analysis suggests that the practice of combined treatment should not be encouraged	1
Nabais M. ¹⁵	2009	Children with fever	In most of the studies included the combined therapy was shown to be slightly superior than monotherapy; Important questions: small samples, lack of placebo control group, double-blinded population, use of incorrect doses of medication	1
Hay AD, et al. ⁷	2006	Children (6 months-6 years)	Limited evidence under the safety profile, efficacy and cost-effectiveness of combined therapy with acetaminophen and ibuprofen	1
Table 1: Systematic Reviews EL: Evidence Level				

Table 2

Entity	Authors	Year	Recommendations	EL	SR
Italian Pediatric Society Guidelines ¹⁰	Chiappini E, Venturini E, Principi N, et al.	2012	Acetaminophen and ibuprofen are the only antipyretics recommended in children; Combined or alternated use of acetaminophen is not recommended	3	B
American Family Physician ⁸	Hoover, L	2011	Further evidence is necessary to verify that the use of combined treatment can be used routinely in children's fever	3	B
NICE ¹⁷	Richardson M, et al	2007 (revised 2013)	Consider using acetaminophen or ibuprofen in children with fever and that appearing discomfort; Only consider using these alternated antipyretics if discomfort persists before the next dose	3	B

P-0396**Montelukast and allergic rhinitis in children: is there evidence?**C. Pina¹, J. Pais¹, M. Lopes²¹Cuidar Family Health Unit, Santa Maria da Feira, Portugal²Famílias Family Health Unit, Santa Maria da Feira, Portugal**Background & Aim**

Allergic rhinitis (AR) is one of the most common chronic diseases of childhood. In Portugal, montelukast is not yet approved in symptomatic treatment of AR.

The aim of this review is to assess the effect of montelukast on the reduction of AR symptoms.

Methods**Data Sources**

A search for meta-analyses, systematic reviews, clinical guidance and controlled and randomized clinical trials was conducted in Medicine Based on Evidence databases (National Guideline Clearinghouse, Guidelines Finder, Canadian Medical Association Practice Guidelines Infobase, The Cochrane Library, Clinical Evidence, DARE, Bandolier and Pubmed).

Review methods

Articles included were published between January 2006 and February 2015 in English, Portuguese and Spanish To assess the quality of the studies and establish the strength of recommendation the Strength of Recommendation Taxonomy (SORT) scale of the American Family Physician was used.

Results

29 articles were obtained from the research, of which five met the inclusion criteria: one controlled and randomized clinical trials and four standards of clinical guidance. Montelukast appears useful in the treatment of AR with different recommendations between seasonal and perennial AR.

Conclusions

The majority of standards of clinical guidance analyzed showed a decrease of allergic symptoms with montelukast in seasonal AR. However, in perennial AR more studies with higher quality are needed to clarify evidences and establish recommendations.

Child sleep disorders in family medicine practice.Clinical study 2003-2014

Valeria V Herdea¹, Laura T Comnea(herdea)², Lidia T Soldea(herdea)³, Alexandru T Herdea⁴, Teodor Gh Herdea⁵

¹Herdea Valeria private practice Bucharest, Romania

²Comnea Laura private practice Bucharest Romania

³Soldea Lidia Emergency Hospital Bucharest Romania

⁴Herdea Alexandru Medicine University Bucharest

⁵Herdea Teodor private practice Bucharest

Background: The high frequency of sleep disorders in children, the negative mark on somatic and neuropsychological development, challenges in finding optimized solutions for early detection and correct treatment, determined this study.

Aim: Presenting the impact of sleep disorders in pediatric pathology

Objectifs

1. Children sleep disorders issue in family medicine practice
- 2.Cause–effect relation study in sleep pathology.
- 3.Prevention, diagnosis, early treatment correlation with quo ad vitam prognosis in patients with sleep disorders.

Study design

This retrospective observational study covered a period between 2003-2014. In that period we have 129,732 consultations, from 0-95 years old, in two family medicine practices(Total=3800 patients).70.5% of requests for medical services are children 0-18 years, from wich, age 0-5 years, represent approx.48%. 50% of children under 5 years present respiratory diseases, of which 24% -severe forms, mostly in cold season(Romania-7 months/year).We observed: consultations/years, age, sex, respiratory diseases (respiratory disfunction, ear infections, hearing loss, need for prosthetic, neurological simptoms, acute and chronic sleep disorders) About 35% from patients accused sleep disorders. Analysis revealed multiple causes: 34.5%organic causes(35% epilepsy, 21%enrolled in functional brain syndrome disorders, 2%tumors, post-traumatic states 8%, 20% infectious pathology, 7%autoimmune, 7% other causes)and 65.5% are functional.

We present: patient approach, decision tree/algorithm, co-morbidities, treatments, interdisciplinary communication role

Conclusion

- 1.In the past 6 years, the addressability to the GP’s in the issue of sleep disorders has increased by over 15% comparing with the first 6 years of the study as result of educational activities: for HCP=patient centered care and oriented especially to patients.

2.The "sleep disorder"="tip of the iceberg" that announce a large number of chronical diseases and whoose care are extremly burdening for the GP's.

3.Presentation, active early detection, diagnosis, monitoring of sleep disorders are vital, because long-term implications are severe, impacting the entire existence of the patient and high cost for society.

Keywords: sleep disorders, interdisciplinary team, communication, education, patient centered care

P-0398

"Why is my penis different?" HYPOSPADIAS DIAGNOSED IN PRE-ADOLESCENCE: A case report

Ana Beatriz Figueiredo, Mariana Gayo, Maria Manuela Bernardo, Pedro Alves
USF das Conchas, Lisbon, Portugal

INTRODUCTION: Hypospadias is one of the most common congenital anomalies, with a worldwide incidence between 0.3 to 0.7% of male births. It results in an abnormal opening of the male urethra on the ventral side of the penis or scrotum causing large impact on the genitourinary function.

This idiopathic disease has multiple risk factors associated to its development, such as advanced maternal age, gestational diabetes, exposure to estrogenic compounds, family history of hypospadias and toxic exposure.

Hypospadias is usually detected in the newborn examination and surgical correction should be performed within the first 18 months of life.

CASE PRESENTATION: An 11 year old boy, belonging to a nuclear family, with 2 siblings, denies any personal history of previous diseases or hospital admissions. Both parents are smokers. At the age of 8, he experienced a urinary tract infection with dysuria and haematuria and he was medicated with antibiotics. The boy began to mention to this mother that he was unable to void without straining. Furthermore, his father often commented that this penis was "crooked and very unusual". At the age of 11, during routine physical examination, it was diagnosed paraphimosis and hypospadias. He was referred to pediatric surgery for surgical correction.

COMMENT: The general practitioner or family doctor plays an extremely important role in the identification of hypospadias in global health examination during the first year of life in order to perform surgical correction on time. Late diagnosis is uncommon. Patients with hypospadias often develop low urinary tract symptoms like urinary stream changes and recurrent urinary tract infections. This disorder may also have an impact in patients' self-perception, particularly in preteens when they are starting to unveil their own body.

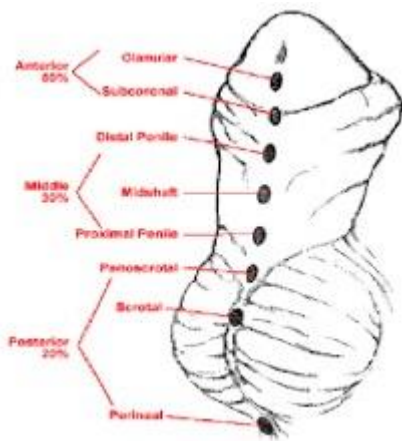

In case of late diagnosis and surgical correction, the risk of post-surgical complications increases significantly.

Keywords: Hypospadias, paraphimosis, preteen, late diagnosis, pediatric surgery

A Sudden Onset of Bladder Bowel Dysfunction in a Child: A Case Report

Inês Domingues Teixeira, Ana Menezes Sanches

Unidade de Saúde Familiar Ribeira Nova, Acs Lisboa Central, Lisboa, Portugal

BACKGROUND & AIM: Lower Urinary Tract Symptoms (LUTS) in children are one of the most common conditions in Primary Care. They may cause considerable physical and psychological distress to children and their families. In this case, the sudden onset of LUTS, perceived by a worried mother, opens a wide range of differential diagnostics.

METHOD: We report the case of a 4-year-old girl who is brought by her mother because of urgency and pollakiuria with 15 days of evolution. She voids 15-20 times per day and has no history of enuresis, incontinence or other symptoms. The condition has started a week after taking an antibiotic for an upper respiratory tract infection. Her physical examination was normal. All the exams requested (urine and blood analysis, ultrasound of the urinary tract) were normal. One-month after closely work with her mother, to understand and identify symptom patterns and behaviors, the major cause identified was a chronic constipation. A treatment plan, based on positive reinforcement, behavioral techniques and dietary adjustments was established and, gradually, a clinical improvement was noticed.

RESULTS: The initial approach aimed at excluding acute or severe causes of LUTS through complementary exams. After normal results and a comprehensive approach of medical and behavioral factors, bladder bowel dysfunction (BBD) became the most probable cause. Although BBD is a frequent condition, the sudden onset of the symptoms is an unusual presentation. The respiratory infection seems to be the triggering factor. Most of the patients with BBD respond to urotherapy and don't need medications or surgical procedures.

CONCLUSIONS: This case report represents an example of the role of Family Doctor in evaluating and treating LUTS. The sudden onset of the symptoms allowed us to describe all the steps required to do this approach. At the end, this case revealed a less typical presentation of BBD.

One door to open

Vítor Portela Cardoso¹, Paula Mendes², Cláudia Melo¹

¹USF Gualtar, ACES Cávado I, Braga, Portugal

²USF Maxisaúde, ACES Cávado I, Braga, Portugal

Background and AIM: Imperforate hymen (IH) is one of the most common congenital anomalies of the female genital tract (1/2000). A rare complication is the dilatation of the vagina (hematocolpos) secondary to retention of successive menstruation. The clinical presentation is highly variable: from an asymptomatic form until symptoms related to the obstruction and local compression. Timely treatment is important to prevent adverse consequences in the sexual and reproductive lives.

METHODS: Case report.

RESULTS: We report the clinical case of a 11 years-old teenager without a family doctor and a history of multiple episodes of use of health services in the last 4 months by pain in the lumbosacral region associated with pollakiuria and dysuria. On January 6, 2013, she came with his mother to an urgency medical consultation in primary health care with the same complaints. Faced to a female teenager on Tanner stage IV without menarche, the physical examination was performed, diagnosing an IH associated with hematocolpos. The teenager was quickly referred to the referral hospital, where it was conducted an himenotomia with a favorable outcome and resolution of complaints.

CONCLUSION: This case report shows on one hand the beneficial impact of the child and juvenile health programmes on the primary care settings by its periodic examinations. On the other hand, seeks to draw attention to inequalities in the primary care in Portugal.

Keywords: imperforate hymen, hematocolpos, primary care, adolescent health, child health

Faint: Syncope... Rhabdomyolysis

Ibrahim Güneş¹, Özden Gökdemir¹, Gizem Çiçek², Nilgün Özçakar¹

¹Dokuz Eylul University Medical Faculty Department Of Family Medicine

²Dokuz Eylul University Medical Faculty Department Of Pediatrics

Aim-BACKGROUND: Rhabdomyolysis occurs by release of creatine kinase in an injury to muscle tissue. Triads of symptoms are myalgia, weakness and dark urine. Common cause of rhabdomyolysis among children is viral infections. Others include trauma, connective tissue diseases, toxins and exercise.

CASE: The patient admitted to Emergency Service because of fainting in changing room before sports lesson. He didn't remember syncope moment.

Physical examination: Conscious, Glasgow Coma Rating:15, Reflexes:Active, Systemic examinations:Normal. During follow-up he vomited 3 times. Right after syncope declared TA:160/90mmHg. ControlTA:125/75mmHg CKMB:300U/L, BUN:24mg/dl, Creatinine:2.27mg/dL, Aspartate transaminase:1328U/L, Myoglobinuria in spot urine(1miyoglob>1100) and proteinuria(p/cre 3.6). Hydrated (3000cc/m2 5%saline) and fluid intake and urinary output were noted.

Urinalysis: pH:6.0 HC03:200mEq Uric acid:9.52. Allopurinol was started for urinary alkalinization. rr' pattern and right axis deviation was noted on Electrocardiography and monitored. GFR was 66, calculated with Schwartz formula. Urine output was 0.9 cc/kg/h, single dose mannitol of 0.5 g/kg administered.

Renal Doppler Ultrasonography:Bilateral increased parenchyma echogenicity. Abdominal CT:Ordinary Patient was admitted to Pediatric intensive Care Unit with acute renal failure. Patient was stable during follow up. MAP was >65, RR:18/min. EEG:Normal. Urinalysis: Hb:10mg/L, protein:0.5g/L, erythrocyte:38, WBC:7. Daily urinalysis was performed.

DISCUSSION: Viral myositis is self-limited in children, but causes muscle weakness and rhabdomyolysis in rare cases. Many virus leads myositis, influenza is the most common. It leads benign acute childhood myositis, progresses to rhabdomyolysis rarely. It's presented with failure to active or passive dorsiflexion or refuse to walk.

Severe rhabdomyolysis presents serious complications such as renal failure, fluid-electrolyte abnormalities, cardiac arrhythmia etc. Other complications are respiratory failure due to necrosis in respiratory muscles/muscle weakness, infection and pulmonary embolism. Patients cure completely with adequate treatment in many cases. As family physicians, we want to emphasize in this case consideration myoglobinuria in macroscopic hematuria and although rare is to attempt preventing complications,

Childhood Obesity – Management in Primary Care Setting

Pedro Cardoso Ferreira¹, Sara Cunha², Sophie Sousa²

¹Unidade de Saúde Familiar Dunas, Unidade Local de Saúde de Matosinhos

²Unidade de Saúde Familiar Oceanos, Unidade Local de Saúde de Matosinhos

Background & Aim

Childhood obesity is increasing at an alarming rate worldwide. According to the European Commission, Portugal is one of European countries with more overweight children, with one in three children being obese. The BMI percentile for age and gender in youths determines whether the child is overweight (BMI \geq 85th percentile and $<$ 95th percentile), or obese (\geq 95th percentile). Portuguese Association Against Childhood Obesity's 2013-2014 data shows that 33,3% of the children between 2 and 12 years old are overweight, and 16,8% of which are obese. It is imperative that health care providers identify overweight and obese children so that counseling and treatment can be provided.

The aim of this review is to propose an algorithm to help the management of overweight and obese children in the primary care setting.

Method

PubMed based review study was made. Review articles, guidelines and clinical orientation norms between 2010 and 2015 were included.

MeSH terms: children, overweight, obesity, pediatric obesity and primary care.

Results

If a child is overweight or obese, the evaluation should identify treatable causes and comorbidities, starting with a complete history and physical examination. The proposed algorithm enables these children's management, including eventual laboratory and radiological screening, therapeutic approaches and indications for referral.

Conclusions

Primary prevention is essential against overweight and obesity.

One of the six core competences of family physicians is primary care management, so it is important to master effective and appropriate health services utilization to reach efficiency.

Pediatric obesity is associated with long-term health consequences. The main focus of primary care physicians should be finding and changing behavioral and environmental factors, which can be modifiable during childhood. An early intervention is efficient and can delay or prevent a referral.

Keywords: MeSH terms: children, overweight, obesity, pediatric obesity and primary care.

Protocol of Orthopaedic Infantile follow-up of the Upper Member in Primary Attention Care

Rosario Martinez Fuerte¹, Iker Sierra Martinez², Leticia Sierra Martinez¹, Natalia Sanz González³

¹Valladolid Este Primary Assistance Gerency, Castile and Leon Sacyl, Valladolid, Spain

²Traumatology Department, Hospital of Medina de Campo (Valladolid), Spain

³Parquesol Senior Center, JCYL Social Serices Gerency, Valladolid, Spain

Background

Centring the professionals of primary care on the managing of the orthopaedic infantile pictures of the upper extremities of major demand on the consultations.

Methods

Develop a Protocol of Orthopaedic Infantile follow-up of the upper Member in Primary Attention Care.

RESULTS:

The child skeleton is a cartilaginous sketch that, as it grows, is capable of suffering physiological alterations or not, in his development and correct formation, due to multiple factors, for what him knowledge of the normal thing and the abnormal thing for every phase of the musculoskeletal development will do us to feel more comfortable as doctors responsible for the primary care before an orthopaedic infantile problem. A precise diagnosis will take us to an appropriate treatment, that is to say, necessarily, in that the benefits are major that the risks and the negative psicosocial effects. So much Pediatricians, Doctors of Primary Care like Infantile Orthopaedists we have attended children controlled unnecessarily, or that have suffered the use and abuse of treatments ortésicos unnecessary.

CONCLUSIONS:

The authors propose this protocol with the intention of centring the professionals of primary care on the managing of the orthopaedic infantile pictures of the upper extremities of major demand on the consultations, frequently phases and variations of the physiological development of the child, for his correct follow-up, diagnosis and / or derivation the specialist if this way it proceeds.

⁴Adana Numune Training and Research Hospital, Department of Otorhinolaryngology, Adana/Turkey

BACKGROUND: Hearing loss is the most common congenital defect worldwide and also the sensory loss affecting psychosocial and academic development of children most. We aimed to evaluate the risk factors in the babies undergoing hearing screening tests and to evaluate the adequacy of the services given to the mothers in primary care.

MATERIAL-METHOD: This cross-sectional study was conducted with 253 babies between 1 March 2014 and 30 April 2014. A structured questionnaire form was applied and the results of the Transient Evoked Otoacoustic Emissions (TEOAE) and the Auditory Brainstem Response (ABR) tests were recorded. Chi-square and Mann-Whitney U test were used for data analysis. Fisher's exact test was applied in 2x2 tables and Monte Carlo simulation was applied in r x c tables. A p level of <0.05 was accepted as statistically significant.

RESULTS: Mean age of the babies was 29.1±45.3 days. Ratio of failure increased as age increased (p=0.0001). The ratio of the mothers who experienced a systemic disease during pregnancy was higher among the babies who failed the test (p=0.031). Eighteen babies failed the tests and were referred to another institution for further evaluation. Consanguinity (25.7%), staying for longer than 5 days in newborn intensive care unit (23.7%) and the

mother's experiencing a systemic disease during pregnancy (10.7%) were the main risk factors. Of the mothers, 79.4% (n=201) stated that they were satisfied from the services given in primary care, 78.7% (n=199) stated that family physicians cared them much.

CONCLUSION: Hearing loss should be detected in the early period, because these children may achieve speech, cognitive, social and emotional development close to their peers through providing a proper hearing device and commencing regular hearing rehabilitation programs early.

Case Report: Postnatally acquired neonatal varicella despite maternal immunity

Grace Lum

Division of Family Medicine, Department of Medicine, National University Health System, Singapore

Background and aim: Neonatal varicella is usually transmitted in utero, and can be severe and fatal. Less commonly, it is acquired postnatally. It is widely understood that transplacental transfer of maternal immunoglobulins protects neonates from the varicella zoster virus (VZV), while their innate immunity is immature. We report a case of neonatal varicella occurring in a full-term infant, born to a mother who attained immunity to VZV in her childhood, and review existing literature of similar cases.

METHOD: Case Summary. A 20 day old neonate, born full term with good birth weight, developed a varicella rash, with no known history of exposure. Diagnosis was confirmed with detection of VZV DNA in infant serum. Antenatal and perinatal history was unremarkable, and household contacts were unaffected. His mother had varicella as a child, and immunity was confirmed through laboratory testing of antibody levels. The neonate was treated with intravenous acyclovir for 10 days, and recovered uneventfully.

Results: In healthy term infants, placentally transferred immunoglobulins equal or even surpass maternal levels. There are 4 previous case reports of neonates developing varicella following exposure to siblings with varicella, despite maternal immunity. Another 5 cases of infants 1-2 months old who acquired varicella during an outbreak were reported, who had pre-existing detected VZV antibodies but with low titres. In all cases, disease course was mild. Infection occurred likely in presence of low maternal titres. Varicella zoster immune globulin (VariZIG) can be considered following exposure in some cases. Acyclovir is used for severe varicella and is generally not required after 2 weeks of age.

Conclusion: Maternal varicella antibodies do not necessarily prevent infection in neonates, but reduce severity of illness. Despite known maternal immunity, physicians should remain open to diagnosis of neonatal varicella, and also educate parents on exposure prevention, such as isolating infected siblings.

Keywords: neonatal varicella, maternal antibodies, passive immunity

Image 1

Generalised vesicular varicella rash developed on this previously-well 20 day old neonate, though his mum was immune and would have presumably given him protective antibodies.

Henoch Schönlein Purpura Accompanied By Cerebral Involvement: A Case Report

Pınar Fakirullahoğlu, Özlem Özer, Halime Pınar Demiröz, Kenan Taştan
Atatürk University, Medical Faculty, the Department of Family Medicine and Research and Application Center for Methods of Acupuncture and Complementary Medicine, Erzurum

INTRODUCTION: Henoch Schönlein Purpura (HSP) is a small-vessel vasculitis most common during childhood. Its etiology is unknown. It is accompanied by arthralgia and purpura, and frequently has gastrointestinal and renal involvement, and 1 % cerebral involvement. It is usually self-limiting and benign. We are going to present the case of a 14 year-old boy complicated with convulsion as a result of cerebrovascular involvement.

The CASE: A 14 year-old male patient consulted upon having complaints of abdominal pain, vomiting and rash starting at the feet and spreading upwards that began two days ago. He was observed to have rashes starting at the medial malleolus of the two feet and spreading upwards, not fading when pressed, not itchy, macular vasculitis. The abdominal examination indicated common sensitivity and other systems were found to be normal. In the first examinations of the patient GGK (+), there was trace protein in urogram. The patient had numerous abdominal pain attacks and had sensitivity in abdominal examination; however the feature was not observed in the standing abdominal x-ray and abdominal USG. No findings were observed in favor of invagination, either. The biochemical parameters, taken when he was observed to have generalized tonic-clonic style convulsion lasting 3-4 minutes, were normal. The cranial CT and neurological examinations were normal, he was not observed to have meningeal irritation signs, and a treatment of 1 mg/kg/day dose prednol was started.

Results and DISCUSSION: HSP is a benign vasculitis causing serious musculoskeletal system, gastrointestinal system, kidney and, though rarely, central nervous system involvement. The cerebral involvement rarely seen in our patient showed itself with generalized tonic-clonic convulsion. In conclusion, as seen in our case, it should not be forgotten that patients followed with pre-diagnosis of HSP may have headaches, mental state changes or cerebral involvement coming with convulsion.

Keywords: purpura, cerebral, convulsion

What Mothers Think About Breast Milk Banks in Turkey?

Zeynep Sayın Dincer¹, Aybüke Demir Alsancak¹, Zeynep Keskin¹, Duygu Ayhan Başer¹, Gökhan Dincer², Yakup Alsancak³, Ufuk Beyazova⁴

¹Department of Family Medicine, Ankara Numune Training and Research Hospital, Ankara, Turkey

²Department of Family Medicine, Ankara Training and Research Hospital, Ankara, Turkey

³Department of Cardiology, Ankara Atatürk Training and Research Hospital, Ankara, Turkey

⁴Department of Social Pediatri, Gazi Üniversitesi, School of Medicine, Ankara, Turkey

Background and AIM: If new born baby's don't reach own mother's milk for any reason, human milk bank provide this baby's nutritional needs from donor mother. These institutions collect, screen, processes and dispepses milk and all these procedure are made according to international standardization methods. Breast milk banking studies in Turkey being continued but quite different opinions has been raised about issues medical and socio-cultural dimensions. The aim of the study was to determine knowledge and views of women living in Ankara towards breast milk banks.

METHOD: The descriptive research was conducted between August - July 2014. The study population comprised women who gave at least one birth and who presented to Gazi University Medical Faculty Hospital Social Pediatri polyclinic. The data were collected by a questionnaire form developed by researchers. The questionnaire form included open-ended and closed questions regarding the descriptive characteristics and about knowledge and views of mothers on milk banking. Data were analyzed with SPSS 16.

RESULTS: We interviewed 440 mothers but showing here the preliminary results from the first 100 participant. Of the women surveyed, 58% indicated they had not previously heard anything about breast milk banking. 65.0% said that they could donate their milk. 48,5% Of mothers who do not want to donate their milk stated that they

would not have enough milk and 40% of them said it constituted a problem from a religious aspect. 51% would not accept donated breast milk for their baby. There were three main reasons of not to accept bank's milk. Respectively: fear of transfer of diseases (41.1%), religious beliefs (39,2%), and grudge (9%).

CONCLUSIONS: Although a lot of discussion, poor knowledge on the matter was observed. As long as detailed records are kept and sufficient knowledge is given to the mothers, milk banking seems appropriate for women.

Prevalence of Bullying and victimization rate among School children at Riyadh City, KSA

Mohammed Abdullah Alrowaily, Mostafa Abolfotouh, Hind Alshatri, Abdulrahman Kariri, Omar Mudifer
King Saud bin Abduaziz University for Health Sciences

Aim. Bullying among school-aged adolescence has been recognized as problematic behavior among adolescents, affecting school achievement, pro-social skills, and psychological well-being for both victims and perpetrators. This study aims to determine the prevalence of Bullying and its types amongst school adolescents.

Methods. In a cross sectional study, 2588 school adolescents at governmental schools (n=2093) and Selective Private schools from Riyadh city(n=495), ages 12-15 years, were subjected to the Peer Relation Questionnaire (PRQ) for Bullying. This questionnaire contains 3 sub-scales (Bully scale, Victim scale, and Pro-social scale). Data on personal characteristics of the adolescent (age, sex, school grade, adolescence stage), family related data (marital status of parents, family coherence, consanguinity, number of children in the family, social class, education and occupation of both parents), history of chronic and or psychiatric diseases (conditions) in the family, were collected. Descriptive and analytic statistics were applied and significance was considered at $p \leq 0.05$.

Results. Significantly higher percentage mean scores of bullying on PRQ were shown in early adolescent ($f=11.03$, $p < 0.001$) female students ($t=7.13$, $p < 0.001$), in private schools ($t=5.24$, $p < 0.001$). Female students showed significantly higher score for bully scale (45.0% versus 36.8%, $t=16.08$, $p < 0.001$), pro-social scale (76.3% versus 71.7%, $t=7.19$, $p < 0.001$) and significantly lower score for victim scale (37.2% versus 42.0%, $t=8.70$, $p < 0.001$) than male students. After adjustment for potential confounders, female gender ($t=4.78$, $p < 0.001$), earlier adolescence stage ($t=3.35$, $p=0.001$) and private schooling ($t=5.24$, $p < 0.001$) were significant predictors of bullying among adolescents.

Conclusion. Bullying and victimization are common among Saudi early adolescents in private schools, with more bully among females and more victimization among males. Timely bullying prevention and interventions are necessary, with a special focus on students in private schools.

LACK Of Vitamin B12 LEVELS In CHILDHOOD ANEMIA OXIDATIVE STRESS DETERMINATIONTünay Kontaş Aşkar¹, Zeynep Hünkerler², Bilge Sönmez³¹Department of Biochemistry, Faculty of Science Çankırı Karatekin University, Çankırı, Turkey.²Government Hospital of Çankırı, Çankırı, Turkey.³Çerkeş State Hospital, Çankırı, Turkey

One of the most frequent nutritional deficiency in children is vitamin B12 deficiency which plays a crucial role in oxidative metabolism and cellular immune response. Megablastic anemia can develop in growing children due to the insufficient intake of animal protein resulting in vitamin B12 deficiency. The aim of this study was to determine malondialdehyde (MDA), nitric oxide (NO), miyeloperoxidase (MPO), paraoxonase (PON), glutathione (GSH), and vitamin E levels in childhood vitamin B12 deficiency anemia.

The study has performed on 18 children with vitamin B12 deficiency anemia and 18 healthy children between the ages 4-9 (6,1±1,4). Vitamin B12 deficiency in children has been determined with Hb level <11,5 gr/dL, and vitamin B12 levels of <200 pg / dL. The study has been performed with the permission of Bülent Ecevit University Ethical Commission.

In the study, MDA, MPO, and NO levels were significantly higher in the vitamin B12 deficiency group and PON, GSH and vitamin E were significantly lower when compared to the control group.

In this study, the fact that oxidative stress occurs in children with vitamin B12 deficiency anemia has been identified high MDA, NO, MPO and low GSH and vitamin E levels.

Keywords: Children, vitamin B12 deficiency anemia, oxidative stress

"{Vocal cord dysfunction: A case report}"

Vishal Mallusingsh Baghele¹, Dhiren Gupta²

¹Department of family medicine, Sir Ganga Ram Hospital, New Delhi

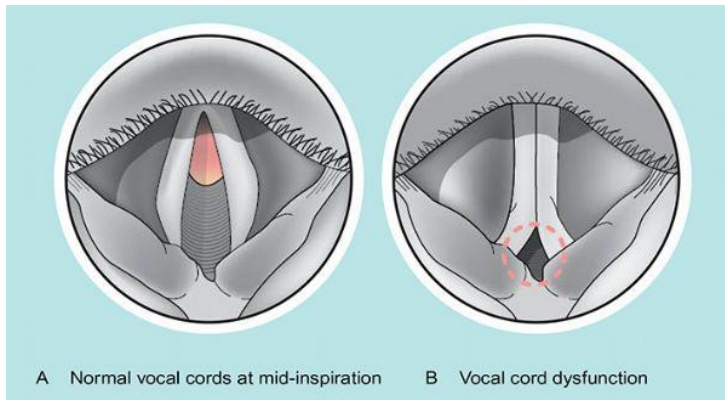

²Department of paediatrics, Sir Ganga Ram Hospital, New Delhi

Vocal cord dysfunction (VCD) is a condition characterized by paradoxical closure of vocal cord. This condition results in symptoms like wheezing, stridor, shortness of breath, anxiety, hyperventilation, suprasternal and neck muscle retraction. VCD is a condition that closely resembles asthma, making the two entities difficult to differentiate symptomatically. Family physician may misdiagnose vocal cord dysfunction as exercise induced asthma or asthma which is refractory to treatment. Misdiagnosis of this condition leads to inappropriate treatment and often patients have been treated unsuccessfully with high dose corticosteroids and bronchodilators that have led to iatrogenic side effects.

The present case report describes a 7-year-old male child presented to OPD with signs and symptoms resembling bronchial asthma since 8 months. Child was unresponsive to the treatment of bronchial asthma. This forced us to think about different diagnosis. With the help of paediatric pulmonologist, bronchoscopy was done which revealed abnormal adduction of vocal cord during respiration. This confirmed us to the diagnosis of VCD. We managed child with speech therapy, psychotherapy, panting exercise and ipratropium bromide inhaler. Child improved symptomatically on this line. Child is now asymptomatic on successive follow up in OPD. So this concludes that family physician should think in a different direction when bronchial asthma patient does not respond to the treatment.

Keywords: Vocal cord dysfunction, asthma, airflow limitation, family physician.

VOCAL CORD DYSFUNCTION

TREATMENT OPTIONS FOR VOCAL CORD DYSFUNCTION

Speech therapy

Psychotherapy

Panting Exercise

This maneuver causes the adducted vocal cords to relax, which increases the glottic aperture.

Anticholinergic agent inhalation

Topical lidocaine

Helium-oxygen therapy

TREATMENT FOR VCD IS VERY SIMPLE.

Factors Related To Prognosis in Children On Antiepileptics

Didem Kafadar

Bağcılar Training and Research Hospital, İstanbul, Turkey

AIM: Epilepsy is an important chronic disease in pediatric population. We aimed to assess the factors related to the prognosis of children diagnosed with epilepsy and receiving antiepileptic medication.

MATERIAL-METHOD: Records of patients referred to pediatric outpatient clinic diagnosed as epilepsy and followed for 6 to 24 months were analyzed. Sociodemographic factors, epilepsy history laboratory and radiologic data were evaluated. Patients who were regularly followed-up for 2 years were described as the coherent group. Descriptive statistics and Chi -Square, Kruskal Wallis and Mann Whitney-U tests were used.

RESULTS: There were 87 patients consisting of 36 girls(41.4%) and 51 boys(58.6%), mean age was 67.7±38.6 months. Distribution of epileptic syndromes was not different between sexes. 74 patients did not have a family history, EEG was pathologic in 68 patients. After 6 months regular follow-up, 44 patients had normal EEG. 59.7% had generalized seizures. First seizure was mostly between 0-2 years of age (44.7%). 43.8% of patients referred to the outpatients clinic in the first 24 hours after the first seizure. In the coherent group(n=45,52%), 38 patients did not have any seizures. The mean time patients were on medication was 19.8±8.0 months. There was a significant difference between the frequency of seizures in 24 months between coherent and noncoherent group. As the age of the occurrence of first seizure increased, period between seizure and admittance to outpatient clinic decreased.

CONCLUSION: Family history, type of both epileptic syndrome and antiepileptic did not affect the prognosis. Regular follow-up decreased relapses and increased remissions. Because of late referrals due to inadequate awareness of families, the patient cannot be evaluated when the seizures begin. Family medicine(FM) is very important in follow-up of chronic diseases. Routine pediatric follow-ups including laboratory assessments and asking about different symptoms are important in FM practice. Chronic conditions of pediatric patients should alert the FM doctors for regular referrals to secondary outpatient clinics for better prognoses.

Chickenpox in Small Infant

Ricardo Oliveira¹, Pedro Ribeiro Oliveira², Rita Almeida¹, Rute Carvalho³

¹USF Escariz, ACeS Feira/ Arouca, Escariz, Portugal

²USF Fiães, ACeS Feira/ARouca, Fiães, Portugal

³USF Ermesinde, ACeS Maia/Valongo, Ermesinde, Portugal

INTRODUCTION: Chickenpox is a common childhood rash disease. Although usually benign, when it occurs at 2 months old and due to immunological immaturity, may raise fears and doubts regarding the evolution and the approach.

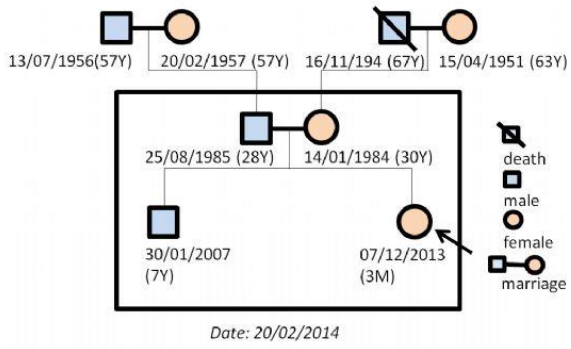

Case Description: We report the clinical case of a 2 months old small infant, without pathological antecedents appealing to primary care for discrete vesicular rash without systemic signs in the context of varicella occurred in her brother 2 weeks before. Sent to the Referral Hospital which confirmed diagnosis, having been admitted under intravenous acyclovir therapy, with favorable clinical outcome.

DISCUSSION: Chickenpox in young infants is infrequent at Primary Health Care. However, with a vesicular rash and no history of contact with an affected individual, doctors have to consider this diagnosis regardless age and presentation form. There's still some controversy in what concerns to treatment and conservative measures may be considered when at the presence of mild illness.

CASE REPORT: CRICOPHARYNGEAL BAR

Çiğdem Hardal, Zuhal Aydan Sağlam

Istanbul Medeniyet University, Department of Family Medicine, Istanbul

CASE: CRICOPHARYNGEAL BAR

7.5 month old baby boy was admitted to our clinic with nasal regurgitation of food, wheezing and failure to thrive. He was born 3410 gr (50th perc) with c-section at the 39th week of gestation. Due to transient tachypnea of the newborn, he was followed up for 3 days in neonatal intensive-care unit. At the first month visit, he was at 25th percentile of weight (3850g) so formula milk was added to breastfeeding. The baby had acute otitis media and pneumonia at 1.5 months of age. Nasal regurgitation accompanied to clinical findings of infection. Although the infection was treated, his complaints hadn't resolved. The complaints might have been due to gastro esophageal reflux, so anti-reflux treatment was started. Sweat test, allergy testing, immunological tests all gave negative results. Despite a slight recovery with anti-reflux therapy, weight gain problem continued. At the sixth month, weight percentile was below 1 percentile (5430grams), so nasogastric feeding was started. He gained weight in two weeks. But he was still 6000gr at 7.5 months when re-consulted to pediatrics department. The presence of nasal regurgitation and wheezing required further investigations so videoflouroscopic swallowing study was planned. This investigation revealed cricopharyngeal bar (picture). The patient was then referred to pediatric surgery. After endoscopic balloon dilatation wheezing and nasal regurgitation completely resolved. The patient gained weight with oral feeding and benefited from the treatment. At 10th month, the patient was 9050grams (25.p) and being monitored for weight gain.

DISCUSSION AND CONCLUSION

31 cases over 65 years old were reported in literature. As far as we are concerned, ours is the first case reported with cricopharyngeal bar at this age, so we find it important to be reported. Although it is very rare, it will be smart to keep cricopharyngeal bar in mind at children with nasal regurgitation, growth retardation and wheezing.

P-0414**systemic juvenil idiopathic arthritis as a cause of fever of unknown origin**

Çiğdem Hardal¹, Muferet Erguven², Zuhal Aydan Sağlam¹, Gizem Huyuk², Hasan Hüseyin Mutlu¹

¹family medicine

²pediatrics and child health

INTRODUCTION: Systemic Juvenile Idiopathic Arthritis (JIA) fever, is a rare inflammatory disease of an unknown origin which may have symptoms unrelated with joints. Diagnosis is made by eliminating infection, malignancy and rheumatological diseases. Here we present a case who had been admitted with eruption on body and on swollen, painful ankles and diagnosed as systemic JIA.

CASE PRESENTATION: Five years old female patient was admitted with rashes and itchiness on her body and additional swelling and pain at her ankles. Eruption and itching on her knees and elbows occurred three weeks prior to admission and she had been prescribed antiallergics before. During three weeks, she had fever on and off reaching to 40°C. She was hospitalized to investigate the etiology of fever of unknown origin (FUO). At admission; body temperature was 36.5°C, heart rate:80/min, respiratory rate:17/ min., BP:90/60mmHg. She had swelling in ankles, and maculopapular rashes all around body especially at extremities (Picture 1).

FUOs may be caused by infectious diseases, malignancies, collagen vascular diseases, or a variety of miscellaneous disorders. The diagnostic approach depends on a careful analysis of the history, physical findings, and laboratory tests and biochemical evaluation. Here, mycoplasma, chlamydia, toxoplasma, rubella serology and testing for anti dsDNA, ASMA, AMA, anti SSA, ANCA, anti SM, anti SSB were negative. Rheumatoid factor was 9.94 IU/ml (<19). Histopathology of bone marrow eliminated malignancy. The patient was diagnosed with systemic JIA based on anamnesis, physical examination and exclusion of infectious and neoplastic disorders by laboratory results. Pulse steroid therapy of 30mg/kg/day for three days and subsequently additional methotrexate therapy for 10mg/m²/wk along with 2mg/kg/day steroid was started. On the sixth day of therapy the symptoms were under control. She was discharged on the third week and is still on 8mg prednisolone and 10mg/m²/week methotrexate.

CONCLUSION: Systemic JIA has to be kept in mind especially in patients with multi system involvement.

Keywords: systemic JIA, fever of unknown origin (FUO)

When to use statins in adolescents

Mara Matos Dias

Unidade de Saúde Familiar de Fiães, ACES Feira - Arouca, Aveiro, Portugal

Background & AIM:

When cardiovascular (CV) risk factors are present from an early stage to adulthood, a risk of future cardiovascular disease is associated. Therefore, the identification of this population creates the opportunity to prevent the development of risk factors and CV events. In this sense, it's created the recommendation for screening, treatment and monitoring dyslipidemia in adolescence at risk for developing cardiovascular disease.

METHOD:

Literature search of systematic reviews and scientific articles from the Pubmed database, and Medline. Restricted to articles published between the period 2009 to 2015, in English.

Results

After the adolescent screening for cardiovascular risk factors and dyslipidemia, the orientation of the primary care physician develops towards taking preventive practice. Beginning with six months of healthy lifestyle measures which, if don't result in a lipid profile improvement, the statin should start to be use.

In general, statin therapy isn't recommended before the age of 10 years, unless there is a significant family history of CV conditions or premature events. Treatment should start with the lowest available dose. All statins, except pitavastatin, have been approved by Food and Drug Administration (FDA), for use in children.

The goal of treatment is to achieve low density lipoprotein - cholesterol (LDL-C) <130 mg / dL. If the desired value isn't reached, then, the dose of statin should be increased and liver function tests, such as aspartate aminotransferase and alanine aminotransferase, should be repeated in 4 weeks.

The safe use of statin at a long term in children is still controversial. However, a periodic follow-up liver enzymes and creatine kinase should be performed.

Conclusions

New recommendations should be created in order to support the safety profile of statins in adolescents. However, it's important to include the preferences of the adolescent and family in treatment decisions, encouraging to share questions and concerns.

Establishing The Knowledge, Attitudes And Behaviors Of High School Students Regarding Energy Drinks

Hamit Sırrı Keten¹, Oğuz Işık², Hakan Öney³, Fatış Yıldırım², Numan Güvenç², Özgür Ersoy⁴, Mustafa Çelik²

¹Department of Family Medicine, Kurtul Family Health Center, Kahramanmaraş, Turkey

²Department of Family Medicine, Medical Faculty, Kahramanmaraş Sutcu Imam University, Kahramanmaraş, Turkey

³Faculty of Arts and Humanities, Arts, Sciences & Technology University in Lebanon, Beirut, Lebanon

⁴Department of Public Health, Medical Faculty, Cukurova University, Adana, Turkey

BACKGROUND: The present study aims to determine the knowledge, attitudes and behaviors of high school students regarding energy drinks.

METHOD: The present study included students from eighteen high schools located in the city center of Kahramanmaraş in the Mediterranean Region of Turkey between 01.04.2015 and 30.04.2015. Students were informed prior to the study and 2168 students giving written consent were included in the study. The participants were administered a questionnaire that was prepared by the investigators.

RESULTS: 1,291 (62.0%) students were female, 877 (38.0%) students were male; and the mean age was 15.81 ± 1.01 (min=13, max=20) years. 1,072 (49.4%) students stated that they drank energy drink before and 1,096 (50.6%) students stated that they did not. 582 (66.4%) male students and 295 (38.0%) female students stated that they drank energy drink before. The energy drink experience was significantly higher in male students than female students (p=0000). 442 (20.4%) students stated that they used energy drink before doing exercise. 492 (22.7%) students stated that they had their first energy drink for trying purposes (curiosity). It was found that the students obtained information on energy drinks mostly from the reminders written on the energy drinks (n=425, 19.6%). 315 (14.5%) students stated that energy drinks increased mental performance and 974 (44.9%) students stated that energy drinks increased exercise performance. 937 (43.2%) students stated that energy drinks were harmful to human health.

CONCLUSION: The present study revealed serious mistakes in the knowledge, attitudes and behaviors of students regarding energy drinks. Almost half of the students were found to have an energy drink experience. Specifically, male students were found to consume more energy drinks compared to female students.

An Anomaly Encountered In The Follow Up The Healty Child: Preaxial Polydactyly

Aynur Yalçıntaş¹, Püren Cura Ecevit², Özlem Öztaş³, Burcu Kayhan Tetik⁴

¹Konya Karatay No:9 Family Health Center, Konya, Turkey

²Konya Meram No:25 Family Health Center, Konya, Turkey

³Ankara EÜAŞ Health Department, Ministry of Energy, Ankara, Turkey

⁴Inonu University Medical Faculty, Department of Family Medicine, Malatya, Turkey

INTRODUCTION:

Polydactyly is defined as having more than five fingers or toes, and is the most common congenital anomaly of the upper extremity after syndactyly. It can be seen either an isolated malformation or as a part of the syndrome. Divided into three groups as radial (preaxial), central, and ulnar (postaxial). Preaxial (radial) polydactyly is the most common subtype, it was reported to be seen in one in 3000 live births. Two surgical approaches have been accepted as basis for treatment of Radial polydactyly. The ideal time for surgery is between 6 months and 2 years old.

CASE:

In systemic examination of a six month old girl during routine follow up, a preaxial (radial) anomaly was detected in the right thumb. Other systemic examinations were normal. Detailed anamnesis revealed that the baby was born after in vitro fertilization (IVF) therapy. We learned that the mother didn't use any medication or exposed to radiation during pregnancy. The parents were informed that this may be a condition that can occur only in the

fingers or may be associated with other organ disorders, and can be resolved by surgical procedures. The baby was referred to the department of plastic surgery and reconstruction.

CONCLUSION:

The goal of surgery in congenital anomalies is to preserve and increase the hand functions or at least to provide an acceptable appearance of the extremities. The follow-up of infants and children on a regular basis in family medicine centers is crucial for the protection of children's health, and regarding their development. The purpose of the follow-up of healthy children is to prevent certain childhood diseases and injuries, reduce preventable deaths, promote development, and ensure them healthy lives as adults. We think the timely follow-up and paying attention to the quality will contribute to the development of children's health.

⁶First Paediatric Department, Medical School, Aristotle University, Thessaloniki, Greece

Childhood obesity, which in Greece holds one of the highest rates worldwide, is predictive for adult morbidity and mortality. The aim of this study was to investigate the strength of potential risk factors (demography, socioeconomic, and nutrition) for childhood overweight or obesity in a pediatric population from Kavala, Northern Greece.

335 children participated (181 boys and 154 girls), with a mean age of 11.02 ± 0.60 years. A structured questionnaire concerning the socioeconomic status of the family, anthropometric values and educational status of parents, diet history, dietary habits, the availability and dietary intake of various food products and beverages at home, physical activity, time sleeping, and time watching television was completed by one of the parents of each child at home.

The prevalence of overweight and obesity was 33.7% and 15.8%, respectively. The frequency of both fathers and mothers with obesity was higher among obese (13.5%) and overweight (6.3%) children compared with normal-weight children (2.4%). Obese children used to have 3 meals or fewer per day significantly more frequent (32.6%) compared to normal-weight (19.5%) or overweight children (23.9%), whereas their meal duration was significantly reduced compared with both normal and overweight children (16.63 minutes vs 20.08 minutes and 19.64 minutes, $P=0.007$ and $P=0.021$). Finally, 22.6% of obese children spent more than 3 hours per day in front of a screen compared with only 8.9% and 8.9% of normal-weight and overweight children.

Our study confirms the increased rates of overweight and obesity among Greek children and identifies paternal obesity, decreased number of meals per day and increased time in front of a screen as risk factors, whereas maternal tertiary education was found to be a protective factor. Preventive interventions should focus on these risk factors for childhood obesity and developing strategies to reduce them.

A Case Report: Sexual Abuse

Püren Cura Ecevit¹, Aynur Yalçıntaş², Burcu Kayhan Tetik³

¹Konya Meram No:25 Family Health Center, Konya, Turkey

²Konya Karatay No:9 Family Health Center, Konya, Turkey

³Inonu University Medical Faculty, Department of Family Medicine, Malatya, Turkey

BACKGROUND

Sexual abuse is using a child which has not completed his/her psycho-social development by an adult for his/her sexual satisfaction. Prevalence of sexual abuse is thought to be %5-8 for men and %12-17 for women. When children which were exposed to sexual abuse send back their homes. It was observed that %5-10 of them were killed and %35-50 of them were seriously damaged in the following process. Sleep disturbances, nightmares, phobias, physical complaints and anxiety disorders were seen in sexually abused children.

CASE

15-year-old girl was admitted to our clinic with sleep disturbances and self-harming behaviors. It was identified that she was raped by someone who she doesn't recognize from their village and in the following period she was taken to an emergency service because of nausea and it was understood that she was pregnant in the lights of several tests. Taking her to the children protection center and sending to an obstetric center for termination of pregnancy were decided by prosecution, then curettage was performed. In her physical examination findings were normal. In her psychological examination; avoiding from contact; self-harming and psychomotor agitation were observed. She was referred to adolescent psychiatry clinic. The girl was diagnosed with post-traumatic stress disorder and it was relieved 3 months after anti-depressant drug initiation. Decreased ongoing Depressive affect and avoidance behavior were completely passed after six months therapy.

CONCLUSION

Role of family physicians in abuse cases are defining the damage in children, keeping in touch with other specialist, managing the treatment and following-up patients in long-term. Story of child abuses in a family is usually in a relationship with abuse of mother that's why investigating the domestic violence is really important. To be careful and sensitive in this regard especially for family physicians will prevent possible abuse cases in the future.

case report: rickets

Ege Özince, Mehmet Ziya Gencer, Seçil Arıca

department of family medicine, okmeydanı eğitim ve araştırma hastanesi, istanbul, turkey

16 months old girl;

Patient was brought to family doctor with complaint of curvature development in the legs after start walking.

Patient's medical history:

During mother's pregnancy; there was no illness and drug using history.

Normal spontaneous vaginal delivery, from healthy mother, weigh 2900 g. in birth

Full-term birth, born smoothly, no difficult birth story.

The mother had come to doctor control during pregnancy

Patient received breast milk for the first 6 months.

After 6th month; breast milk has been completely cutten and food supplement has been started.

The vaccines are being made regularly since the birth.

The patient, who was holding her head 2 months old, sitting unsupported 8 months old, has started walking 1 year old.

Vitamin-D and iron prophylaxis haven't been begun to the patient.

Patient's family history:

No relationship between parents,

3rd child of family,
no illness in the family,
the patient's other siblings are right, healthy.

Physical examination:

Weight:8800 g (25.-50. pers) Height:74 cm (50. Pers)

Head circumference:45 cm (25.-50. pers)

The paleness, closed fontanelle, caput quadratum head deformity and rarity of hair were present.

There were no feature of the patient's cardiovascular and abdominal examinations.

Metaphyseal swelling in the patient's wrist and ankles and O-bien deformity in the patient's legs were detected.

In the chest examination; in deep inspiration, respiratory Harrison Groove was observed.

Breath sounds in both lungs by listening were natural and equal.

Imaging:

In the X-ray taken of the patient's lower extremities; metaphyseal significantly cupping up and irregularities and also in the bone widespread lack of osteoid matrix were detected.

Treatment:

After evaluating the patient history, physical examination and laboratory findings, the patient was diagnosed with "Nutritional Rickets" and 2000 U/day vitamin-D and 50 mg/kg/day Ca (p.o) have been begun to patient, also called to regular control.

An audit of the measurement of weight and height in children with asthma between the ages of 5-12 years in a rural practice

Deborah Ryan, Heather Mccullagh, Sheila Casey, John Macmahon
Kingscourt Surgery, Kingscourt, Co Cavan

Objective

1. To identify all children with active asthma within the practice to ensure they are correctly coded
2. To check if children with asthma have had their height and weight recorded in the last 12 months.

Methods

A search was performed using Socrates software to identify children between 5-12 years old coded with asthma diagnosis.

All files examined, to see if

1. these patients had active asthma
2. they had been reviewed in last 12 months
3. height and weight had been recorded.

Searched for all children in target age prescribed ICS (beclometasone and fluticasone) or montelukast in last 12 months to identify uncoded asthma cases.

Practice meeting held to discuss coding and plans made to measure weight and height of asthmatic children.

A review was conducted 4 months after the initial intervention.

Results

55 patients identified within the age range who were coded with a diagnosis of asthma. 5 were excluded from the analysis as they were not active patients in the practice.

Our post audit results showed a 350% increase in the number of children with height recorded and 260% increase in those with weight recorded. When we looked only at patients symptomatic in the last 12 months, 14 (58%) had height and weight recorded.

We identified 18 children using ICS or Montelukast who were not coded as asthmatic. Of these 18 patients, one(5.5%) child had height and weight recorded pre audit which increased to 8(44.4%) post intervention.

Following review of these 18 charts 14 children were coded as asthmatic.

Discussion

Using only a brief simple intervention we increased practice awareness of best practice in asthma management for children and clearly identified all asthmatic children within the practice.

Hypertension in a private school versus a state school

Mehtap Gömleksiz, Hakan Demirci, Hayri Bozkurt, Esra Beşir Mahsun

Department of Family Medicine, Sevket Yılmaz Training and Research Hospital, Bursa, Turkey

AIM:

Hypertension in children is more prevalent than it is in the past. There are so many articles related to high blood pressure seen in school age children. In the present study we aimed to compare hypertension frequency between a private school and a state school.

METHODS:

There were 466 students in the state school and 166 students in the private school we visited.

Blood pressure measurements were performed in two separate visits and average results were calculated. The average blood pressure results were evaluated according to the fourth report criteria.

RESULTS:

The mean age of children was 7.5 ± 1.2 in private school and 7.7 ± 1.2 in state school (range was 6-11 years). Ten children (6%) out of 166 were determined to be hypertensive in the private school whereas there were 35 children (7.5%) out of 466 were diagnosed as hypertensive in state school. There was no statistically significant difference between these two schools in terms of hypertension ($p=0.52$). Hypertension was more prevalent in boys compared to girls ($p=0.005$).

CONCLUSIONS:

The frequency of hypertension is similar between state schools and private schools. Boys have a greater risk of having hypertension. To prevent hypertension in public we should focus on children because they will carry all the risks to their future life.

P-0423**Retrospective Analysis of Childhood Poisoning in Ümraniye**Caner Araz¹, Tuğba Okur², Şirin Güven², Mustafa Özgür Toklucu²¹Clinic of Family Medicine, Ümraniye EAH, Istanbul, Turkey²Clinic of Pediatrics, Ümraniye EAH, Istanbul, Turkey**Background & AIM:**

Poisoning cases who had applied to Ümraniye Research and Training Hospital Pediatric Emergency Unit, below the age of 17, between January 2010- December 2012 were evaluated retrospectively.

METHOD: For statistical analysis; NCSS (Number Cruncher Statistical System) 2007&PASS (Power Analysis and Sample Size) 2008 Statistical Software (Utah, USA) is used. The results that $p < 0.05$, are considered remarkable.

RESULTS:

Poisonings accounted for 0,3% of total pediatric emergency visits. Patients (n: 1129) aged between 1 months-16 years ($5,37 \pm 5,02$ years); 590 were female whereas 539 were male (1,09/1). Poisonings were more frequent under 5 years; 13 months- 4 years group consisted 39,4% and 0-12 months 21,7% of all cases. Accidental poisonings (82,5%) were more frequent than suicides (17,5%).

Accidentals poisonings were common in boys under 5 years though suicidal poisonings were common in 12-16 year old girls. Evaluation of the poisoning agents according to the age groups; drug ingestion became the most common poisoning reason except for 8-11 years group CO/NFIA exposures were more common. Poisonings occurred more frequently in March and in spring. Drugs (%62) were the most common poisoning agents. Analgesics- antipyretic (21,17 %) and central nervous system medication (13,64%) poisonings were leading other drugs. CO/NFIA (16,8%) and caustic-corrosive substances (9,4%) were the most common non-pharmacological agents.

Nausea- vomiting and tachycardia were the most frequent symptoms-signs; although the majority were asymptomatic.

CONCLUSIONS:

Our study reflects the demographic properties of poisonings in our region and will contribute to undertake preventive measures for childhood poisoning in Turkey.

Evaluation of Home Care Services Provided for Children Patients

Dursun Çadircı¹, Enver Kepenek¹, Mehmet Örenler², Elif Burcu Yavuz¹, Ahmet Güzelçiçek²

¹University, Faculty of Medicine, Department of Family Medicine, Sanliurfa, Turkey

²Sanliurfa Children's Hospital Home Care Unit, Sanliurfa, Turkey

Background & AIM: Home care service refers to services of examination, workup, test, treatment, medical care, follow-up and rehabilitation including social and physiological services at home or in a family environment for individuals who need home care service delivery(1). Homecare services have gained importance in our country in recent years and this study attempts to evaluate children patients followed-up by home care unit and service provided.

METHOD: Sociodemographic characteristics and diseases of patients followed-up by HomeCareUnit at SanliurfaChildren'sHospital together with service they receive were evaluated retrospectively. Data was collected through records information of patients who got services between February-April,2015 at HomeCareUnit.

RESULTS: A total of 167 patients were registered at HomeCareUnit. Total of 152 patients whose data was obtained were included in study. 57% of the patients(n=87) were males and 42% of them(n=62) were females.

Mean age of the patients was 11±4.2. Disease distribution provided in Table1.

2% of patients(n=1.3) were feeding with percutaneous endoscopic gastrostomy, 3.9% of patients (n=6) were with NG, and 94.7%(n=144) were feeding orally.

32.2% of patients(n=49) were those who were given wheelchair, nebulizer, airbed, suction apparatus and ventilator by officials and aid organizations in accordance with their needs. Distribution of devices provided is available in Table2.

Most frequent complaint in doctor visits was coughing with percentage of 28.3(n=43). Second most frequent was fever with 17.8%, constipation was %10.5(n=16), vomiting %4.6(n=7), pressure sore %3.3(n=5). 50.7% of patients did not have any complaint during visits.

Primary care was given by mother in 92.8% of patients in our study. None of patients had a paid nurse.

CONCLUSIONS: Home Care Service is one of newly developing health services in our country and we are of the opinion that studies with wider scopes are needed.

Staphylococcal scalded disease

Tuğçe Refika Turan, Fisun Sözen, Ali Ümit Geçkil

Department of Family Medicine, Baskent University, Ankara, Turkey

INTRODUCTION: Staphylococcal scalded disease is an issue characterized with bulla and exfoliation caused by exfoliative toxin also called with epidermolytic toxin, epidermolysin, exfoliatine. It is mostly seen under 5 years old children especially in autumn and winter seasons. It usually starts after upper respiratory tract infection, otitis media, conjunctivitis caused by staphylococcus. It is characterized with fever, irritation, skin sensitivity, erythema. Lesions become widespread across the face, axilla, inguinal area respectively. Nicolsky sign is positive. There is no mucosal involvement. Typical 'scalded' skin symptoms reveal about 24-48 hours after disease starts.

CASE: 3 days before the admission to the pediatric emergency room she had nasal flow, weakness, fever. Second day there was rash surrounding her mouth and she became irritable. Fever was decreasingly continuously. At third day rash became widespread throughout her body, and then peeled. When she applied to emergency room there was bullous, locally degloved erythematous lesions on her mouth, neck and abdomen. Nicolsky sign was positive. Body temperature was 37 C. Her past medical and family history, laboratory tests were found to be normal. She received vancomycin, clindamycin antibiotherapy for 7 days. In the hospitalization period, culture tests were all negative. After dermatology consultation, hamamelis virginiana distillate and zinc oxide pomade were offered. The case was discharged with complete recovery after 7 days.

CONCLUSION:. Staphylococcal scalded skin syndrome generally diagnosed with its characteristic clinical symptoms and our case also diagnosed with the same group of clinical symptoms. Its therapy is always inpatient treatment with the use of parenteral antibiotics. Since antibody against staphylococcal toxin are immature and renal system can't excrete exfoliative toxin the incidence in children is higher. should take anamnesis and do physical examinations carefully to refer in order to make the patients treated appropriately.

Thyroglossal Ductus Cyst Presenting With A Neck Lump: A Case Report

Süheyla Atalay¹, Müferet Ergüven², Zuhale Aydan Sağlam¹

¹Department of Family Medicine, Istanbul Medeniyet University Goztepe Training and Research Hospital, Istanbul, Turkey

²Department of Pediatrics, Istanbul Medeniyet University Goztepe Training and Research Hospital, Istanbul, Turkey

INTRODUCTION: Thyroglossal cysts (TGCs) arising from a persistent epithelial tract, represent the most common congenital anomaly of the neck. Symptoms can arise from the swelling itself or from complications, the most significant of which is infection. The diagnosis can usually be made from the history and a careful servical and physical examination. **AIM:** To point out to the possibility of thyroglossal cyst which is one of the most common congenital anomalies of the neck among servical masses in children. **CASE:** An eight year old boy presented with a 2-3 cm hyperemic, mobile and tender lump on the location of hyoid bone for a week. His systemic physical examinations were normal. His laboratory results were as follows; haemoglobin:11,8 g/dL, Hct: %35, Plt: 444.000 mm³, WBC:15900 mm³, CRP:5,2 mg/dL, TSH 0.6437 uIU/mL, fT₃ 3.4 pg/mL, fT₄ 1.25 ng/dL. Ultrasonography imaging showed that the thyroid gland had normal size and ecogenity but there was a heterogen 17x24x10 mm sized solid lesion at the neighbourhood to the sternothyroid and sternohyoid muscles, located in the middle line of the neck, at the same location with the hiperemic lump, containing cystic material at the anterior part. Multiple ovoid lymph nodes were also observed in usg imaging at the superior posterior servical chain. The patient was diagnosed as infected thyroglossal ductus cyst and intravenous antibiotics were prescribed. At the fifth day of the treatment the palpable lump has shrunk and tenderness decreased. Blood test results returned to normal levels. The patient was consulted with the department of otorhinolaryngology and invited for regular appointments by that department. **RESULTS:** TGCs may be asymptomatic but malign degeneration can be observed at 1 % and infection may occur at 50% of cases. Possibility of this genetic abnormality should be in mind in cases presenting with tender and mobile lump in front of throat.

child development vocation high school students education levels and opinions about child negligence and abuse

Nagihan Yıldız Çeltek¹, Gülseren Oktay¹, Şükriye Sakar³, Ufuk Ünlü¹, Osman Demir²

¹Department of Family Medicine, Gaziosmanpaşa University Medical School, Tokat, Turkey

²Department of Biostatistics, Gaziosmanpaşa University Medical School, Tokat, Turkey

³Department of Child Care and Youth Services, Gaziosmanpaşa university social sciences vocational schools, Tokat, Turkey

AIM: In this study, to detect that education levels and opinions of child development vocation high school students who have significant role on 0-6 age group child care, and to raise awareness about this topic are aimed.

METHODS: For the sampling of the descriptive study, 197 students were chosen attending to Gazi Osman Paşa University Child Development Department. To obtain data, a questionnaire was administered to students. Chi-square test, standart deviation, average methods are used for analysing data.

FINDINGS: Regarding 190 chosen students, 188 were female, 2 were male, 18(9,5%) expressed that they had been subjected to violence, 26 that they had been exposed negligence. 20 student received official education about negligence and abuse. Regarding reason of abuse and negligence reporting obligation, 175 (93,1%) students think that they have to report because of laws, 164(88,6%) students think that they have to report because of National Education Ministry policy, 181(95,8%) students think that they have to report because of moral reasons. When they identified abuse and negligence, 88 (47,3%) students think to report to social services, 73(39,2%) students think to report to police department. The rate of student who think that able to identify physical abuse is 29,1%(55). 176 (94,1%) students express that they require more education about this topic.

RESULTS: In this study, we detected that child development vocation high school students have not enough education about child negligence and abuse. For to raise awareness and education level of child development staff, education program changes and to take more time for negligence and abuse topics in curriculum programs.

CHILD NEGLIGENCE AND ABUSE

P-0428**Is there a connection between obesity and hypertension**

Esra Baykan, Hakan Demirci, Beyza Demirbaş, Ali Candar, Esra Beşir Mahsun

Department of Family Medicine, Sevket Yilmaz Training and Research Hospital, Bursa, Turkey

AIM: Increase in childhood hypertension is tried to be explained with an increase in obesity prevalence. In this study we aimed to identify if there was a correlation between obesity and hypertension in children.

METHODS: There were 637 children aged 6-10 years. We measured heights and weights of the children. Blood pressure measurements were performed twice and their means were calculated. Evaluation of hypertension was performed as it was described in the fourth report.

RESULTS: There were 45 children with hypertension and 74 obese children. In addition to this there were 73 children diagnosed as overweight. Obesity and hypertension were combined in 23 cases. This relation was statistically significant ($p=0.000$).

CONCLUSION: Obesity and hypertension are tightly comorbid diseases in children. They have common risks and prevention from one of them would probably prevent occurrence of the other.

Keywords: obesity, hypertension, comorbidity, children

P-0429**Childhood hypertension changes by altitude and gender**

Hakan Demirci, Hayri Bozkurt, Ali Candar, Esra Baykam, Esra Beşir Mahsun, Erkut Afyoncu, Fatih Çiftçi, Beyza Demirbaş, Mehtap Gömleksiz, Nevruz Yıldırım, Yakup Akpınar

Department of Family Medicine, Sevket Yilmaz Training and Research Hospital, Bursa, Turkey

AIM: It is well known that high altitude negatively affects blood pressure in general. In the present study we aimed to compare blood pressures in children who live different altitudes.

METHODS: Six hundred and fifteen children living at sea level (group1) and 228 students living at high altitude (850 meters) (group2) were participated in the study. Their blood pressure measurements made. Evaluations of blood pressures were done according to the fourth report criteria.

RESULTS: There were 37 students with hypertension in group1 (6.2%) whereas there were 16 students with hypertension in group2 (7%). There was an interesting gender distribution of hypertension in these two different altitudes. In group1 there were 27 males and 12 females diagnosed as hypertensive whereas in group2 there were 13 female students and only three boys diagnosed as hypertensive. The mean age of group1 was 7.91 ± 1.27 and it was 7.77 ± 1.22 in group2.

CONCLUSIONS: The frequency of hypertension in children is similar at sea level and at a relatively high altitude. There is a paradox in gender distribution of hypertension by altitude changes. Differences in physical activity and diet should be studied in these two locations.

Keywords: blood pressure, hypertension, high altitude, school age children

Which one is more effective estrogen or testosterone on childhood hypertension?

Hakan Demirci, Yakup Akpınar, Ali Candar, Fatih Çiftçi, Yasin Güçlü, Salih Metin

Department of Family Medicine, Sevket Yılmaz Training and Research Hospital, Bursa, Turkey

AIM: Childhood hypertension is a new dilemma. Previous studies have shown that obesity and hypertension spreaded as an epidemic. They have a peak incidence at a time around puberty. In the present study we aimed to investigate relationship between high blood pressure and puberty.

METHOD: There were 343 students participated in the study. Their blood pressure measurements were performed by family medicine trainees. High blood pressure decision was made according to Fourth Report Criteria. Puberty decision was made as it was described in Tanner Staging.

RESULTS: Seventy two girls and 54 boys were diagnosed as in puberty. There were 37 students with hypertension. Hypertension in girls was not associated with puberty, while there was a statistically significant relationship between puberty and hypertension in boys ($p=0.01$).

DISCUSSION: Estrogen has been known to be protective against cardiovascular events. In the present study we have shown that puberty was not associated with hypertension in girls. However, we found that puberty affected blood pressure in boys. We ask 'Is it estrogen protection or testosterone that affects our life?'

Keywords: asymptomatic hypertension, puberty, female, male, children

Carriage of Group A Beta-Haemolytic Streptococci Among Preschool Children

Ayşen Bayram¹, Ayşe Nur Sarı¹, Ahmet Muhammed Harmankaya², Yüksel Furkan Kömürçüoğlu², Nil Çelikkalkan², Burak Özğan², Ramazan Sevim², Yusuf Ökkeş Bağrıyanık², Ece Mahsereci², Eyüb Dündar², Halil Baysöz², Çağlar Mehmet Başaran², Seval Kul³

¹Department of Medical Microbiology, School of Medicine, Sanko University, Gaziantep, Turkey

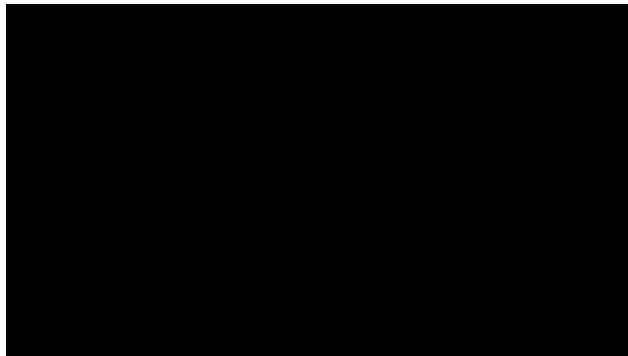

²School of Medicine, Sanko University, Gaziantep, Turkey

³Department of Biostatistics, School of Medicine, Gaziantep University, Gaziantep, Turkey

This study aims to investigate the rate of carriage and possible risk factors for Group A Beta-hemolytic streptococci (GABHS) in throats of preschool children. Children aged 0-6 years who admitted to three different Family Health Centers in the province of Gaziantep, Turkey were included in the study. Patient information sheet issued in order to compile demographic information and determine the risk factors for GABHS carriage were filled for all participants. The throat swab samples taken from volunteers were brought to the laboratory in transport media and were cultured on 5% sheep blood agar plates. Following an overnight incubation, advanced biochemical identification tests were performed to beta-hemolytic colonies on culture for the differential diagnosis of GABHS. The prevalence of GABHS carriage in the study and 95% confidence intervals were calculated using the rate for single-sample Z test. In our study, the prevalence of GABHS carriage in children aged between 0-6 years was identified as 5.8%. Growth of GABHS was observed in three out of 52 children from whom throat swabs were taken. Normal throat flora was detected in 49 (94.2%) volunteers participated in the study. In two of three patients with GABHS carriage, both mother's and father's educational level was primary education. Throat pain was present in two of these children in the last three months. Two GABHS carriers who suffered from bronchitis reported respiratory disease 1-4 times in a year. The rate of GABHS carriage we found in Gaziantep is not high according to results obtained from various studies conducted in our country, however GABHS carriage and infection in children should be monitored carefully because they cause significant morbidity among this age group.

Sociodemographic characteristics and risk factors of children 5-15 years of age with asthma

Nurgül Önder¹, Sami Hatipoğlu², Betül Battaloğlu Inanç³, Derya Sıkar⁴

¹Gaziosmanpaşa ASM, İstanbul.

²Dr. Sadi Konuk Training and Research Hospital, DDepartment of Pediatrics, İstanbul,

³Muğla Sıtkı Koçman University, Faculty of Medicine, Family Medicine Department

⁴6. Nolu ASM, Düzce.

OBJECTIVE: The aim of the study is to determine socio-demographic characteristics and risk factors of children admitted to an outpatient asthma clinic of a research and training hospital.

METHODS: In this descriptive study, records of 450 children 5-15 years of age with diagnosis of asthma admitted to Asthma and Allergy Outpatient Clinic of Bakırköy Dr. Sadi Konuk Research and Training Hospital between January and December 2005 were evaluated retrospectively. Data regarding socio-demographic characteristics, age at onset of the disease and risk factors were analyzed with Student's t test, Mann Whitney U test and chi-square test. The study was approved by the ethics committee (03.04.2007/57) of Bakırköy Dr. Sadi Konuk Training and Research Hospital.

RESULTS: Among the participants 60.9% were male, mean age was 8.4±2.7 and mean age at onset of the symptoms was 3.6±2.7. 95.6% of the participants were coming from low-income families. 46.4% were using coal stove for heating and 67.1% were living in a humid house. Among the children, 66.7% were admitted to an emergency clinic during last year and 10.9% were hospitalized.

CONCLUSION: Socio-demographic characteristics and risk factors of children evaluated in our study were consistent with the literature.

Keywords: Asthma, smoking, breast feeding.

Prevalence of iron, folic acid, vitamin b12 and vitamin d deficiency in patients with thalassemia

Vasfiye Güven¹, Mustafa Kürşat Şahin², Canan Albayrak³, Davut Albayrak³, Mustafa Fevzi Dikici¹

¹Department of Family Medicine, Medical Faculty, Ondokuz Mayıs University, Samsun, Turkey

²Canik Community Health Center, Samsun, Turkey

³Department Of Pediatric Hematology, Medical Faculty, Ondokuz Mayıs University, Samsun, Turkey

Background &AIM: Thalassemia related anemia is a common hematologic problem in Mediterranean region. This type of anemia may be frequently confused with iron deficiency anemia. Anemia becomes more severe in case of coexistence of both anemia types and literature knowledge is sparse on that issue. This study was carried out with the aim of investigation of iron, folic acid, vitamin B12, vitamin D levels in patients who were diagnosed with beta thalassemia.

METHOD: The study represents a retrospective, cross sectional, single-center cohort study. Data were collected from a previously authorized and validated Hospital Information Management System (NUCLEUS). Data were analyzed using SPSS 22.0 package program. In the analysis, frequency and percentage from descriptive criteria were used.

RESULTS: A total of 66 patients (36 male, 30 female) who were diagnosed with beta thalassemia were enrolled in the study. Iron deficiency was detected in 28 (42.4%) patients. Decreased vitamin D, vitamin B12 and folic acid values were detected as 18 (27.2%), 15 (22.7%) and 5 (7.5%) patients, respectively.

CONCLUSIONS: It was concluded that serum iron, folic acid, vitamin B12 and vitamin D levels should also be measured in assessment of beta thalassemia patients due to its high prevalence in study region.

Keywords: Beta thalassemia, iron deficiency anemia, vitamin B12, vitamin D, folic acid

A Case of Varicella Complicated With Preorbital Cellulites

Hatice Dülek¹, Şule Nurşah Ayata¹, Narin Akici², Çiğdem Sağ², Zehra Esra Önal², Çağatay Nuhoglu²

¹FAMILY MEDICINE DEPARTMENT OF HAYDARPAŞA NUMUNE TRAINING AND RESEARCH HOSPITAL, ISTANBUL

²PEDIATRICS CLINIC OF HAYDARPAŞA NUMUNE TRAINING AND RESEARCH HOSPITAL, ISTANBUL

INTRODUCTION: VARICELLA/CHICKEN POX IS A MILD AND CONTAGIOUS CHILDHOOD ILLNESS CAUSED BY THE VARICELLA ZOSTER VIRUS AND CHARACTERISED BY ITCY RASH. VARICELLA PROVIDES A BASIS FOR SECONDARY BACTERIAL INFECTIONS. IMPETIGO AND CELLULITIS ARE THE MOST COMMON SUPERFICIAL SKIN INFECTIONS. CASE: A 6 YEAR OLD MALE PATIENT WITH PAPULOVESICULAR RASH ON BODY AND SWELLING ON THE LEFT EYE 3 DAYS LATER AND ONSET OF PAIN PRESENTED TO OUR HOSPITAL. DURING THE EXAMINATION THE PATIENT WAS CONSCIOUS AND EXTENSIVE PREORBITAL CELLULITIS ON THE LEFT EYE AND VARICELLA RASH ON THE WHOLE BODY WAS PRESENT. THE PATIENT HAD NOT HAD CHICKENPOX VACCINE AND HAD NO IMMUNE SYSTEM DISEASE OR CHRONIC DISEASE HISTORY. DURING LABORATORY TESTS THE FOLLOWING RESULTS WERE FOUND: ANTIVIZVIGM+, CRP; 2.9MG/DL, WBC:16.9K/UL.BIOCHEMICAL TESTS WERE NORMAL. OPTIC DISC WAS FOUND TO BE NORMAL, EYE MOVEMENTS WERE UNRESTRICTED AND LIGHT REFLEX WAS FOUND TO BE NORMAL AT THE EYE EXAMINATION AND THE PATIENT WAS DIAGNOSED WITH ORBITAL CELLULITIS. SURFACE TISSUE USG WAS ORDERED FOR THE SWELLING ON THE CHEEK. THE RESULT INDICATED ABSCESS.

DISCUSSION: VARICELLA WHICH IS ONE OF THE MOST COMMON INFECTIONS OF CHILDHOOD HEALS ON ITS OWN WITHIN 7-10 DAYS. CELLULITIS AND IMPETIGO ARE THE MOST COMMON SUPERFICIAL TISSUE INFECTIONS. THESE INFECTIONS CAUSE SCARS DESPITE PROPER TREATMENT (1-3)SINCE IN SOME COUNTRIES SUCH AS OURS HYGIENE AND HAND WASHING IS NOT WIDELY PRACTICED, REDUCING THE FREQUENCY OF SKIN AND SOFT TISSUE SECONDARY BACTERIAL INFECTIONS ASSOCIATED WITH VARICELLA IS BELIEVED TO BE DIFFICULT. EXTENSIVE ORBITAL CELLULITIS SECONDARY TO VARICELLA IN OUR PATIENT WAS TREATED WITH AN INTENSIVE ANTIBIOTICS TREATMENT WITHOUT LEAVING ANY SCAR.SINGLE DOSE VARICELLA VACCINE WAS ADDED TO THE NATIONAL VACCINATION SCHEDULE IN OUR COUNTRY IN 2013. VARICELLA CAN CAUSE SERIOUS COMPLICATIONS AS SEEN IN OUR PATIENT WHO HAD NOT BEEN VACCINATED AND WE WANTED TO STRESS THE IMPORTANCE OF VARICELLA VACCINE.

Henoch-Schönlein Purpura with Scrotal Involvement

Ahmet Ünal¹, Dilek Yılmaz², Ferah Sönmez²

¹Department of Family Medicine, Adnan Menderes University, Aydın, Turkey

²Department of Pediatric Nephrology, Adnan Menderes University, Aydın, Turkey

INTRODUCTION

Henoch-Schönlein purpura (HSP) is the most common in childhood, the monitoring of IgA deposition in the vessel wall is a small vessel vasculitis that is at the forefront of skin lesions. The most common clinical presentation at HSP; non-thrombocytopenic purpura, abdominal pain, arthralgia or arthritis and renal involvement. Very different clinical manifestations can be traced to the vessels held by HSP. Acute appendicitis, intussusception, the superior mesenteric artery syndrome, acute pancreatitis, esophagitis, duodenitis, acute scrotum, hemorrhagic urethritis, urethral stenosis, muscle involvement are one of the rare clinical presentation. An annual incidence of 14-18/100000 was reported. Although the etiology is not clear, but infections, autoimmune mechanisms, drugs, vaccines, antigen-antibody complexes are accused.

CASE REPORT

Eight-year-old male patient is admitted to our hospital were followed by on the lack of HSP a rash of complaints typical rash in the gluteal and lower extremities. Feature was not in the patient's personal and family history. In physical examination of the lower limbs and gluteal rash typically palpable purpura was present. The patient's scrotum, scrotal edema and was red appearance inspection. Examination was unremarkable in other systems. The patient was hospitalized under observation in the pediatric nephrology service. Complete blood count, blood chemistry, coagulation parameters and urinalysis examinations were normal. Sedimentation 92 mm/hr respectively. Pathologic features not found in C3, C4, PT, PTT, IgA and viral hepatitis markers. Negative occult blood in the stool and abdominal ultrasonographic examination was normal. Scrotal ultrasonography was reported as the fluid accumulation, that done for scrotal edema. 24-hour urine protein levels were within normal limits. All purpuric and scrotal edema disappeared on 5 days of follow-up. He was released from the hospital and was decided to followed as outpatients.

CONCLUSION

HSP should be considered in the differential diagnosis of rash illness should be monitored closely for complications that may occur and system inquiries should be made in detail. We can prevent the morbidity and mortality of patients with complete physical examination. Patients should be referred to the appropriate center if necessary without delay.

4 months old patient with tuberculosis

Ezgi Kaçar, Reyhan Üstündağ, Mehmet Ziya Gencer, Seçil Arıcı
Istanbul Okmeydanı Training and Research HOSPITAL

INTRODUCTION: 4-months-old patient who was diagnosed tuberculosis after contact with tuberculosis patient. Complaints / story: Patient whose complaints began with fever 9 days before and antipyretic treatment, the antibiotics were given to considering upper respiratory tract infections, was consulted to the children emergency service. Patient who had a history of contact with tuberculosis patient was hospitalized in children's services with the preliminary diagnosis of tuberculosis upon non-decreased fever during observation.

Physical examination: Patient with no feature in his prenatal story, had 38 degree fever during consultation.

Breath sounds were bilateral, equal and natural. No feature was observed during all system examinations.

Clinical course: i.v. ceftriaxone was began to apply to the patient after hemoculture. Upon learning that patient had a contact with tuberculosis 2 months ago, patient were consulted with Pediatric Infection Diseases. Patient's 48th hour PPD value has been read 11mm, 72nd hour PPD value has been read 13 mm. On contrast-enhanced chest CT, density increases in mediastinum upper left perihilar area of approximately 17 * 13mm and in posterior mediastinum the largest of about 12 * 7mm size were assessed in favor of lymphadenopathy, density increase in

the anterior apex of the left lung at about 4 * 5 mm in size and density increases in both lung fields especially in the right upper lobe and the central part of right lung, were observed as assessed in favor of frosted glass appearance. Considering the patient's age, history, PPD value and CT, three anti-tuberculosis treatment was started (isoniazid 10 mg / kg / day single dose, rifampicin 15 mg / kg / day single dose, pyrazinamide 30 mg / kg / day single dose). During follow-up, the patient who had no additional complaints and no fever after 3rd day of admission, was transferred to the Infection Clinic.

"{" Level of Knowledge of Child Development Students on Children's Health "}"

Gülseren Oktay¹, Nagihan Yıldız Çeltek¹, Yunus Emre Kuyucu³, Canan Kuzdan², Ramazan Tetikçok¹

¹Department of Family Medicine, Gaziosmanpaşa University Faculty of Medicine, Tokat, Turkey

²Department of Pediatric Infectious Diseases, İstanbul Mehmet Akif Ersoy Thoracic and Cardiovascular Surgery Training and Research Hospital, İstanbul, Turkey

³Department of Biostatistics, Gaziosmanpaşa University Faculty of Medicine, Tokat, Turkey.

"" AIM: Preschool educators who interesting children in the jobs, have knowledge about health information is very important. Because of the requirements in the field of health, especially when it isn't possible to predict the urgent issues arise. The purpose of study was to determine the knowledge of child development students about children's health and emergency response requires

METHODS: the study carried out on the first and last students who in the Gaziosmanpaşa University Child Development Program that recorded demographic information, which previously received first aid training, any course that participate in health or education, whether having child and asked 20 questions about knowledge of child health

RESULTS: 33.7% of first, 51.6% of last class students find themselves enough about child health. The majority of students were found to give the correct answer subject to fire intervention methods, the risks of obesity, personal hygiene, head injury, foreign body lodged intervention. In addition, only half of the students; smudge with airway tuberculosis (1. class:42,1, % last class:50,5%) and " What should be done first loss as a result of the burns on the hot water? "The correct answer to the question which" must be kept for at least 5-10 minutes under flowing tap water " has been found (1.class:43,2%, last class:52,7%) to give correct answer

CONCLUSIONS: Although the average total score of last students (15.27 ± 2.30) is higher than the first students (13.00 ± 2.93) (p <0.001); haven't enough knowledge which is the seen often in the professional life examples, intervention of the patient who corrosive agent ingestion, post -burn and children with fracture risk. Level of knowledge is increasing if the content of the student's education curriculum created problems which is seen often in professional life. In addition, continuity of knowledge should be provided with in-service training after graduation"".

A Case With Spinal Muscular Atrophy Presenting With Reduced Neck Movements

Mehmet Altuğ¹, Melahat Akdeniz²

¹Beyşehir 3rd Görgün Yavuz Family Health Center, Konya

²Akdeniz University, Department of Family Medicine, Antalya

Introduction

Spinal muscular atrophy (SMA) is a neurological disease characterized with degeneration in spinal cord anterior horn cells. SMA type I (Werdnig Hoffman Syndrome) manifests itself during the first 6 week of life. It is the most severe type of the disease. Affected cases have hypotonia, they cannot hold their head or sit, and may lie "frog-legged". Due to the severe weakness of intercostal muscles, the abdomen is displaced upwards resulting in paradoxical breathing. Patients cannot sustain life because of the severe respiratory difficulty unless there is mechanical respiratory support.

THE CASE:

One month old male patient was brought to our family health center with complaints of reduced movements of his neck and high-pitched crying. His overall condition was good, there was fasciculation in his tongue. His deep tendon reflexes were hypoactive. Tonic neck reflex was absent. Muscle was normal, but he had reduced muscle strength. Extremities were hypotonic. He was born from the first pregnancy of his mother. The mother had been regularly checked by her physician with USG examinations during her pregnancy; no abnormality was detected. There was no consanguinity between the mother and the father.

The patient was consulted with pediatric neurology clinic, and he was diagnosed with SMA type I. There is currently no effective treatment of SMA. Symptoms are tried to be minimized with physical therapy, orthopedic interventions and respiratory support. The role of family physician in these kinds of disease with no effective treatment is to educate the family, to provide support for care and to aid in obtaining appropriate rehabilitation services.

CONCLUSION: As well as the commonly occurring diseases, rare diseases, also called the "zebra"-type diseases are also encountered in primary healthcare. Recognition and appropriate management of these rare diseases by family physicians can prevent the family from unnecessary diagnostic and treatment interventions.

Septic Arthritis An Important Causing in Pediatric Population: Brucellosis

Ahmet Ünal¹, Yasin Bulut²

¹Department of Family Medicine, Adnan Menderes University, Aydın, Turkey

²Department of Pediatrics, Adnan Menderes University, Aydın, Turkey

INTRODUCTION

Brucellosis is an multisystemic infectious disease that can be seen all over the world. They are easy to reproduce in wet and humid conditions, can survive so long raw milk and dairy products. Fever, loss of appetite, fatigue, muscle and the nonspecific symptoms such as joint pain, until the symptoms of the affected specific organ present with different ranging clinical manifestations. Brucella can affect many systems, especially musculoskeletal system, cardiovascular system and central nervous system, can cause serious complications. Bone-joint involvement is one of the common complications of brucellosis. Brucellosis is one of the major causes of septic arthritis. In this article, due to Brucella infection and was presented with a child developing knee arthritis in patients who have no symptoms of systemic infection outside the joint complaints.

CASE REPORT

17-year-old male patient was admitted to our clinic with weakness, pain in the left knee, swelling, redness and limitation of movement. On clinical examination; revealed left knee swelling, increased temperature, palpation tenderness and limitation of movement. Measured temperature of the patients was 37.4°C. Laboratory values examined, found that WBC:3980/mm³, hemoglobin 11.4 g/dL, Plt:169000/mm³, CRP:21 mg/dL, erythrocyte sedimentation rate 33mm/h, AST 32 U/L, ALT:30 U/L. Viral hepatitis markers were negative. Patient joint puncture was performed. Fluid was consistent with septic arthritis, was pus appearance. Empirical antibiotic therapy was initiated in patients diagnosed with septic arthritis. Rose Bengal slide agglutination test (+), antibody titers of 1/640 at Wright tube agglutination test (+) found. Patients were considered to be brucellosis septic arthritis. Treatment of patients with TMP/SMX+rifampicin has been changed and were given for six weeks. His complaints to be completely past, revealed that full range of motion on 6 weeks to next check.

CONCLUSION

The most common microorganisms in childhood septic arthritis is Staphylococcus aureus. Brucellosis is an important factor in septic arthritis in the endemic area. Brucellosis comes out with many different signs and symptoms. In particular, joint pain and/or swelling in joints should be considered in children with diagnosis and proper evaluation should be ordered.

Early maternal separation may induce smoking

Yusuf Karayürek, Hakan Demirci, Yakup Akpınar, Fatih Çiftçi, Ali Candar, Yasin Güçlü

Family Medicine, Sevket Yılmaz Training Hospital, Bursa, Turkey

AIM: There is a novel idea that breastfeeding duration of a person is associated with addiction such as smoking. And, it is also known that separation of a child from his/her parents' may result in unwanted psychological outcomes. In the present study we aimed to find out if there was a relation between maternal separation in childhood period and smoking.

METHODS: The study group was composed of all of the students (n=296) in the school. We asked who smokes in the study group to the class advisor teachers and then confirmed the results by the children. Separated children were determined by face to face interviews.

RESULTS: There were 43 high school students with parental separation. Eight of the students were separated from their mothers. Among them two mothers were dead and six were divorced. Sixty one children were smokers in the study group and twelve of them had parental separation and five of them have been separated from their mothers (p=0.12).

CONCLUSIONS: Smoking rate was quite high in a secondary school (20.7%). And, children separated from their mothers have a greater risk of become a smoker.

Keywords: smoking, children, maternal, separation

Infantile Hypertrophic Pyloric Stenosis Case Report

Reyhan Üstündağ, Mehmet Ziya Gencer, Ezgi Kacar, Kamil Demir, Gözde Nizamoglu, Seçil Arica
Department of family medicine, Okmeydanı Education and Researching Hospital, İstanbul, Turkey

INTRODUCTION:

Hypertrophic pyloric stenosis is one of the most common diseases that require emergency surgery in the neonatal period(1) While 2-4 weeks old, non-bilious vomiting is shown after nutrition in this disease and gradually increases; if it is not recognized on time it can cause serious problems. Palpation of hypertrophic pylorus during physical examination (olive sign) and seeing the pyloric muscle thickness 3-4mm, the length 14-16 mm in ultrasonography shows definite diagnosis(1-2). In this case an infantile hypertrophic pyloric stenosis patient was discussed.

Case presentation:

Two months old male patient; was admitted to the pediatric emergency with the complaints of non-bilious vomiting after every nutrition and weight loss. There was no property in the patient's prenatal history. He was 3500 gram of normal spontaneous birth. The patient had dryness of mucous membranes, highly decreased skin turgor. He was 4050 gr. In physical examination there was palpation of hypertrophic pylorus. In complete blood count wbc:18.62 103/UL, hgb:13.2 G/DL, plt:691 103/UL; in biochemistry glucose:74 mg/DL, urea: 24mg/DL, creatinine: 0.28 mg/DL, Na:136 mEq/L, potassium:3.96 mmol/L; in arterial blood gas ph:7.57, PCO2:31.2, BE:5.7 mmol/L, HCO3:27.8 mmol/L. In his abdominal ultrasound pyloric muscle thickness was 4 mm, length was 20 mm. We had diagnosed him as infantile hypertrophic pyloric stenosis. The patient's oral intake had been stopped and we started decompression with nasogastric catheter. We started fluid replacement to the patient according to the sodium-potassium deficit. The patient was transferred to the pediatric surgery department.

CONCLUSION:

Vomiting and weight loss are among the reasons that families resorting Ph.D. most especially in the neonatal period. We can distinguish this type of patients from gastroesophageal reflux, nutritional excess by anamnesis and examination of olive sign in primary health care and we must transfer them to a better equipped hospital urgently.

Peripartum cardiomyopathy can only be diagnosed by primary care physicians

Burkay Yakar¹, Yusuf Haydar Ertekin², Hülya Ertekin³, Aysegül Uludağ², Yasemin Korkut Türkmen⁴

¹Gulabibey Family Physician Center, Corum, Turkey

²Department of Family Medicine, Canakkale Onsekiz Mart University, Canakkale, Turkey

³Department of Psychiatry, Canakkale Onsekiz Mart University, Canakkale, Turkey

⁴Department of Family Medicine, Dumlupınar Üniversitesi, Kutahya, Turkey

Introduction

Peripartum cardiomyopathy (PKM) is a form of congestive heart failure that results from an enlarging of the heart and a weakening of the heart muscle in the last month of pregnancy and in the first five months of the postnatal period.^{1,2} Major risk factors include pregnancy at >30 years of age, multiparity, chronic hypertension and eclampsia.^{4,8} Patients suffering from PKM generally present with symptoms akin to heart failure, and the condition can be considered normal during the late period of pregnancy. A diagnosis of PKM can be made from anamnesis, a physical examination and echocardiography.

Case report

A 34-year old female patient, visiting the family medicine polyclinic for vaccinations of her 1-month-old infant, was noted to be suffering from shortness of breath, palpitations and coughing. There was no medical history of any disease or medication before or during the pregnancy. The patient's blood pressure was 120/70mmHg and her pulse was rhythmic at 122/min. There was no cardiac murmur, rales were present in both pulmonary bases and the results of an abdominal examination were normal. Pitting edemas were observed in both lower extremities, and a further anamnesis revealed that the patient's palpitations had begun two weeks prior to the

birth, and had increased in the first postpartum week. The patient was transferred to a cardiologist due to concerns of heart failure and a pulmonary embolism, and was then admitted to the intensive care unit for treatment with a diagnosis of acute decompensated heart failure.

Discussion

Given the higher incidence of disease in mothers >30 years, and the advanced average age of maternity in the present day, the odds of encountering PKM in the primary care is increasing. Family physicians can overcome this low-prevalence of the disease by investigating risk factors, following-up symptoms and consulting experts.

Knowledge And Attitude of Newly Delivered Mothers About Smoking During Pregnancy and Breastfeeding

Emel Lüleci¹, Neşe Keskin¹, Seyhan Hıdıroğlu¹, Tuba Ekinci², Seyhan Birinci², Esin Yüksek², Burak Tahmazoğlu², Mustafa Şahin²

¹Department of Public Health, Medical School of Marmara University, İstanbul, Türkiye

²Medical School of Marmara University, İstanbul, Türkiye

Background & Aim: WHO deems smoking as the most important modifiable risk factor for non-communicable diseases. Although the number of smokers in developed countries decreases, smoking in Turkey has gone up. The increasing number of women smokers creates risks not only for them, but also for pregnancy and fetus. This study aims to describe smoking behavior of women who have given birth in Marmara University Hospital and to measure their knowledge about effects of smoking during gestation and breastfeeding.

Method: Between 31st March and 13th April 2014, 204 women who have come into the obstetrics and gynecology ward or to the pediatrics clinic of Marmara University Hospital have been included in this descriptive study. After securing permissions from respective departments and consents of the participants, researchers administered a questionnaire by the method of face to face. The data were analyzed using chi-square test in SPSS 22.0.

Results: Mean age of the participants was 28 (SD: ±5.85). 24 (%11.8) participants had smoked at some point in their lives, while 12 (%5.9) of them continue to smoke. 7 (%29.2) women who ceased to smoke did so during their first pregnancy. 16 (%7.8) women stated they smoked during pregnancy, and 8 (%3.9) of them stated they smoked during breastfeeding. 33 (%26.6) of the participants with smokers in the household avoided second hand smoking, while the number of women without smokers in the household was 91 (%73.4) (p<0.05). 4 (%6.7) women with low education level and 20 (%62,5) women who had a higher level of education gave history of smoking (p<0.05).

Conclusions: Smoking women during pregnancy determined to have had inadequate help from health professionals to stop smoking and has a low smoking cessation rate. Primary health care services should actively take part in decreasing the number of smoking pregnant and breastfeeding women.

High parity as an independent risk factor for pregnancy anemia

Gintarė Smalinskaitė, Kazys Simanauskas

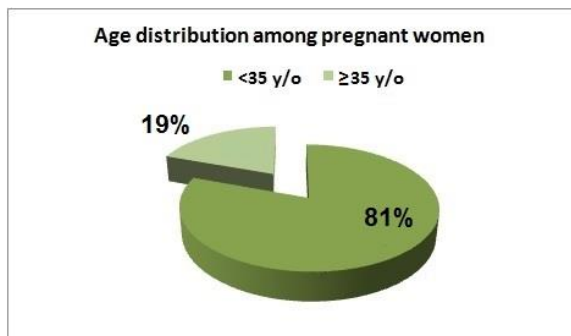

Faculty of Medicine: Clinic of Internal Diseases And Family Medicine, Vilnius University, Vilnius, Lithuania
 Background and AIM: Anemia is affecting 1.62 billion people globally. Anemia occurs at all stages of life but its risk is higher in state of pregnancy due to an increased iron requirement, physiological demand and loss of blood. The aim of the study was to assess high parity (≥5 pregnancies) as an independent risk factor to developing anemia during pregnancy in patients of Family medicine centre of Vilnius university Santariškių clinic, Vilnius, Lithuania.
 METHODS: A total of 360 medical records of pregnant women were included as a study subject from 2010 to 2014. The main hematological indicators (Hgb, Hct, MCV, MCH, MCHC), parity and prevalence of anemia during all trimesters were assessed. The data were processed and analyzed using Microsoft Excel for Windows 2007 and Statistical Package for Social Science (SPSS) version 17.0.

RESULTS: In our study, 2.2 per cent of pregnancies were characterised as high parity. Women with high parity pregnancy had significantly (p<0.05) lower Hgb and Hct levels in first trimester of pregnancy. There was no significant difference in other hematological indicators regarding parity status.

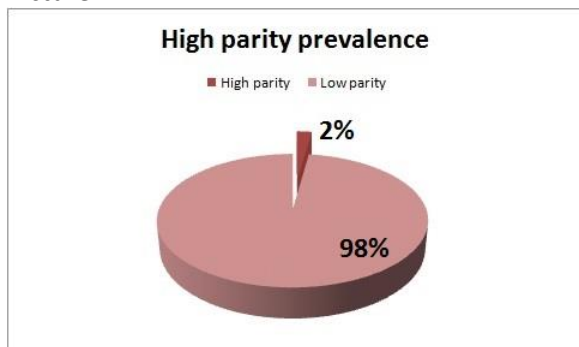

CONCLUSIONS: In this study lower Hgb and Hct levels in first trimester of pregnancy were more frequent in women with high parity suggesting that increasing parity appears to increase the risk of occurrence of pregnancy anemia.

Planned pregnancy rates and research status about pregnancy before planning

Ceyhun Yurtsever, Elif Altunbaş Ateş, Turan Set

Department of Family Medicine, Karadeniz Technical University, Trabzon, Turkey

Background & AIM: In this study, determination of the research before pregnancy and planned pregnancy rates and affecting factors are intended.

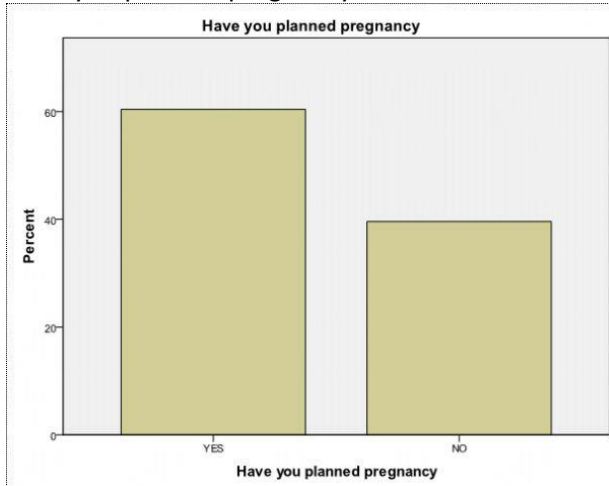

METHODS: This study was performed on the pregnancy clinic, Karadeniz Technical University, Faculty of Medicine in January 2015 as a cross-sectional study. A questionnaire asking patients' demographic characteristics, pregnancy is planned or not and research status about pregnancy before getting pregnant was developed by researchers. This survey was performed in 102 pregnant volunteers.

RESULTS: The mean age of participants was 30.6±6.1 years. Pregnants who had planned currently pregnancy rate was 60.4%. The percentage of those that are doing research for information and consultation before pregnancy was 24.5%. Information resources were family physicians (31.8%), obstetrician (31.8%) and other ways such as internet and books (34.4%). The higher education of the participants state was found to increase the rate of pregnancy is planned (p=0,032). Between participants who research before pregnancy, the answer to question of "to whom did you consult" was changed as "family physician" when the education level decreased (p=0,011).

CONCLUSION: In our study, knowledge about pregnancy planning and pre-pregnancy care has been shown to be minimal, especially for poor socioeconomic status and low educational level. Uncontrolled, successive births and abortions threaten the mother-child health. In our study, the rate of consulting to the family physician was found that increased when patient's education is decreased. This shows the effectiveness and accessibility of family medicine in low socio-economic level. In accordance with knowing that only a quarter of women do research before pregnancy, it suggests that our society is not sufficient consciousness. It must be given attention to family planning and pre-pregnancy counseling services that be given to all women of reproductive age. In this point, family physicians providing health care services to all segments of society have an important role.

Early pregnancy – a family tendency

Adriana Relvas, Maria Miguel Sá, Suzie S. Leandro

USF Famílias, ACeS Entre Douro e Vouga, Santa Maria da Feira, Portugal

Background & AIM: Through a proper family evaluation the family physician should be able to identify risk behaviours with a potential intergenerational pattern. Then, once identified, it is possible to act upon those risk factors.

METHOD: Interview/Family evaluation with patient

RESULTS: MLFS, 46 years old, female, married at 21years of age, pregnant three times, three daughters (first pregnancy wasn't planned and the patient was unemployed at the time). The patient is part of a nuclear family in stage IV of Duvall life cycle. Major consumer of medical appointments. Her first daughter is 25 years old, single and has 2 children (3 and 5 years old), the second oldest daughter is 19 years old and had her only child at 17 (at the time she also was unemployed and the pregnancy wasn't planned). The youngest daughter is 11 years old, hasn't started her sexual activity but in various medical appointments she has stated that her wish is to be a mother, just like her siblings.

When the family evaluation was performed, it was clear that there existed frequent conflicts between the couple and between mother and daughters.

CONCLUSION: Family evaluation instruments are an important tool in Family Medicine. Having in consideration the changes in the family dynamics or through the repetition of risk patterns, in this case a history of non-planned adolescent pregnancies, it is necessary that all the family members readjust their role in the family to support the new members. The youngest daughter should be a major focus point during the preparation of this family with the main objective of stopping this pattern.

Case Report: Approach To Hypothyroidism In Preconceptional Phase

Mehmet Ziya Gençer, Reyhan Üstündağ, Ezgi Kaçar, Gözde Nizamoğlu, Seçil Arica
Department of Family Medicine, Okmeydani Training And Research Hospital, Istanbul, Turkey

INTRODUCTION: Hypothyroidism is the disease which occurs due to the lack or insufficiency of the thyroid hormone at tissue level. While clinical hypothyroidism can be spotted by laboratory data of high TSH and low T4, in subclinical hypothyroidism ST4 levels can be within normal levels. Hypothyroidism is mostly observed at %1-2 during pregnancy and is one of the major reasons for infertility.

CASE: A 30 year old patient with gravide1, parity1, living-child1, planning for pregnancy applied to our family medicine clinic with the complaints of inability to lose weight, continued fatigue, drowsiness, listlessness, intolerance to cold and hair fall. Nothing unusual observed in the patient's physical examination. In laboratory experiments, TSH:11.8mIU/L, T4:0.630, Hb:10.1g/dL, vitamin B12:143.6 pg/mL, iron binding capacity:367.7 µg/dL, serum iron:18µg/dL ve serum ferritin:19.7ng/mL, vitamin B12:143.6 pg/mL was found out. Upon detecting hypothyroidism, the patient's thyroid autoantibodies were checked by her thyroid usg. While her anti-TPO ve anti-Tg levels were seen positive, results of usg was consistent with Hashimoto's disease. The patient was provided 1.6µg/kg of levothyroxin replacement treatment, iron, folic acid and B12. The patient was called for control after 4 weeks and Hb:11.7g/dL, TSH:7.1mIU/L, T4:0.855mIU/L vitamin B12:388.7pg/mL was observed. Levothyroxin treatment continued with an increased dose of 1.9 µg/kg. After 7 weeks, seeing that TSH:2.05mIU/L, T4:1.42 mIU/L, Hb:13.2 g/dL, Vitamin B12:473 pg/mL, the patient was told that she can plan pregnancy after the consultative service of 1 month prior to the pregnancy.

DISCUSSION and OUTCOME: The major reason for hypothyroidism during pregnancy is the lack of iodine. For pregnant women with the sufficient level of iodine intake, autoimmune thyroiditis arises as the most common reason for hypothyroidism. Therefore, family medicine experts should not skip the diagnosis of hypothyroidism prior to and during pregnancy, they rather should initiate the treatment needed and refer the more complex cases to an endocrinologist

Smoking and pregnancy: What to do? – An evidence-based revision

Helena Marques¹, Juliana Pais², Maria Miguel Sá³

¹USF S. Félix da Marinha, ACeS Espinho/Gaia, S. Félix da Marinha, Portugal

²USF Cuidar, ACeS Entre Douro e Vouga, Santa Maria da Feira, Portugal

³USF Famílias, ACeS Entre Douro e Vouga, Santa Maria da Feira, Portugal

Background & Aim

Smoking is the most important preventable cause of adverse outcomes in pregnancy. Helping pregnant women who smoke to quit, involves communicating in a sensitive, patient-centred manner. Cognitive behavioural therapy should be the first treatment option for smoking cessation during this period. The use of pharmacotherapy like Nicotine replacement therapy (NRT) can enhance quit rates in nonpregnant individuals and it is effective and safety.

To determine the efficacy of NRT to support smoking cessation in pregnancy compared with placebo

Method

Comprehensive searches had been conducted in February 2015 on several evidence-based medical database, between January 2005 and February 2015, using MeSH Terms. For the evidence classification was used the Strength of Recommendation Taxonomy (SORT) by American Family Physician

Results

Were identified 32 articles and selected 7. Four guidelines, one systematic review (SR) and two placebo randomized controlled trials (RCT). The main outcome was self-reported smoking cessation at delivery, validated when possible by biochemical measures.

Conclusions

There is currently insufficient evidence to determine whether or not NRT is effective when used in pregnancy for smoking cessation. In all almost studies was observed poor adherence and failure in the use of long courses of NRT. Despite a lack of conclusive evidence, such treatment is recommended by United Kingdom, Australian and Canadian health authorities but not by United States guidelines. Further research is required.

Atypical Preeclampsia

Ayşe Pervanlar¹, Saadet Berrin Yalcin¹, Necdet Suer², Zuhale Aydan Sağlam¹

¹Department of Family Medicine, Istanbul Medeniyet University Goztepe Training and Research Hospital, Istanbul, Turkey

²Department of Obstetrics and Gynaecology, Istanbul Medeniyet University Goztepe Training and Research Hospital, Istanbul, Turkey

AIM

Preeclampsia is a multisystemic illness which presents with hypertension, proteinuria, and edema some time after 20 weeks. Recent data suggest that in some women, preeclampsia and eclampsia may develop in the absence of hypertension or proteinuria. The purpose of this study is to increase the awareness of atypical preeclampsia (Table 1).

CASE REPORT

A 30 year old multipara was admitted to our clinic with regular contractions at 33 weeks' gestation. All her prenatal visits had been normal. Cervix was 2 cm dilated and 40% effaced. Physical examination revealed normal. Laboratory findings and blood pressure (BP) were also normal but she had a dipstick proteinuria of 3+. The intrapartum fetal heart rate recording revealed poor variability and late decelerations. An emergency Cesarean delivery was performed for fetal distress. A male baby weighing 1900 g was delivered with APGAR scores of 4 and 6 at 1 and 5 min. The baby was admitted to the intensive care unit for respiratory distress syndrome. 2 h postoperatively, the mother had a severe headache and visual blurring with a BP of 160/100 mm Hg. MgSO₄ infusion was started with a loading dose 4.5 g over 20 minutes, followed by a maintenance dose of 2g/h as an intravenous infusion for 24 h. Three days later, her complaints resolved and she became normotensive. She was discharged on the 4th postoperative day.

DISCUSSION

However its classic triad is known as hypertension, proteinuria, and edema, recent data suggest that, preeclampsia may develop in the absence of hypertension or proteinuria. In conclusion, the absence of hypertension or proteinuria should not preclude preeclampsia. Fetal distress may be the first presenting scenario in atypical cases. Women who have irregular antenatal visits are at risk for preeclampsia 7 times more when compared to the women who have regular visits. We can prevent bad scenarios by planning regular visits and keeping atypical preeclampsia in mind.

Context of postpartum care: a cross-sectional study

Binali Çatak¹, Can Öner², Sevinç Sütü³, Selçuk Kılıç³

¹Kafkas University School of Medicine

²Istanbul Bilim University School of Medicine

³Burdur Public Health Directorate

An adequate care to be carried out following the birth reduces infant and mother mortality. The main objective of this study is to evaluate the postnatal care services in terms of quantity and context.

The research population consists of 816 women who gave birth. The data collected by a form prepared by researchers basing on Postpartum Care-Management Guide (DSB-YR). Postpartum care was evaluated in terms of quantity, context as well as the factors affecting such context in the study. Data were analyzed with the SPSS 20.0 software package.

All of the women received postpartum care from family physicians and/or family health midwives within 45 days subsequent to being discharged from the hospital. 3.1% of women had one, 57,8% had twice and 39,1% of them had three or more postpartum care. The average number of postpartum care per woman is 2.5 (\pm 0.8). The parameter average per puerpera was 8.5 (\pm 4.1) while its median was 8 (0-16). In conclusion, all women within the study received at least one postpartum care.

Approximately six out of every ten women received care less than three times; and the context of postpartum care is inadequate in terms of the determined parameters.

Infant health and vaccination parameters in unplanned home birth delivery

Binali Çatak¹, Can Öner²

¹Kafkas University School of Medicine

²Istanbul Bilim University School of Medicine

It has been reported that infants delivered at home carry higher risks of morbidity and mortality. Not only that but also their use of health services are quite low. The aim of this study was to determine the vaccination parameters of home birth infants.

The data of this study was derived from part of prenatal and postpartum care of an other study namely "Unplanned home birth and affecting factors in Istanbul". This study was designed as case control study. The "case" group consisted of 168 women who had "unplanned home deliveries" and "control" group (n=367) of women giving birth in hospitals. The data of the study were collected by the researchers using the data collection form. Vaccination determined according to "vaccination schedule of ministry of health". Neonatal screening program attendance was evaluated. Data were analyzed by SPSS 20.0 package program.

9 (5,4%) babies in case group and 2 (0,5%) babies in control group was not vaccinated. Vaccine coverage rate was 94,6% in case group and 99,5% in control group (p=0,000). Male/Female ratio in unvaccinated babies was 4/5 in case and 1/1 in control. In case group only one baby's (0,8%) blood samples for neonatal screening (hypothyroidism, biotinidase deficiency and phenylketonuria) was not taken and this was 3 (0,6%) in control group. For hearing test 36,9% (n=62) of case group and 9,3% (n=34) of control group was not screen for hearing (p=0,001). Although there were a significant difference in coverage rate of vaccination, in both groups the rates were high. For screening only hearing test was significantly low in home birth group.

Vitamin D Levels in Pregnant Women and Umbilical Cord Blood, and Their Relation With Birth Measurements

Ayşe Özlem Kılıçaslan¹, Ruhusen Kutlu², Derya Işıklar Özberk²

¹Karatay Fetih Family Health Center, Konya, TURKEY

²Department of Family Physician, Meram Medical Faculty, Konya Necmettin Erbakan University, TURKEY

Background & AIM: Vitamin D deficiency may result in some significant health problems in pregnancy and fetus. We aimed to measure the levels of Vitamin 25(OH) D, in pregnant women and their neonates, and assess the relation between Vitamin D supplementation and the growth parameters at the neonates.

METHOD: This cross-sectional analytical study was performed with 100 pregnant women at term, and neonates. The blood samples were obtained from the mothers before labor and from the umbilical cord during the labor. The growth parameters of the neonates were measured.

RESULTS: The mean Vitamin D levels of the pregnant were 11.39 ± 6.24 ng/ml, and neonates were 8.00 ± 4.95 ng/ml. Fifty-three percent of the mothers had Vitamin D deficiency (<10 ng/ml) and 47% of them had Vitamin D insufficiency (10-30 ng/ml). Maternal Vitamin D deficiency was detected in 62.3% of the women who did not use a Vitamin D supplement, whereas this rate was 37.7% among the women who used a supplement ($p < 0.001$). The height ($p = 0.004$), head ($p = 0.003$) and chest ($p = 0.005$) circumference of the neonates of the mothers who received Vitamin D supplements were also significantly different. Birth height, head and chest circumference of the neonates of the pregnant women who had Vitamin D deficiency were significantly lower than the measurements taken from the neonates of the mothers with Vitamin D insufficiency ($p < 0.001$).

CONCLUSIONS: According to the results of the present study, the Vitamin D levels of the mothers and the levels measured at the umbilical cord blood were still very insufficient, despite the ongoing Vitamin D supplementation program set for the pregnant women in Turkey. The measures taken to prevent maternal Vitamin D deficiency should be intensified.

P-0453**Study Protocol: An Exploration of Health Professional Support for Breastfeeding- a primary care study**

Puteri Shanaz Jahn Kassim¹, Dayangku Hayaty Awg Dzulkarnain¹, Nurjasmine Aida Jamani², Aneesa Abdul Rashid¹, Nurainul Hana Shamsuddin¹, Maliza Mawardi¹

¹Department of Family Medicine, Faculty of Medicine and Health Sciences, Universiti Putra Malaysia

²Department of Family Medicine, Kulliyah of Medicine, International Islamic University of Malaysia

INTRODUCTION: Eventhough there has been substantial evidence on the benefits of breastfeeding, Malaysia has one of the lowest rates of breastfeeding in Asia. The Malaysia Third National and Health Morbidity Survey (NHMS III) 2006 showed that less than 15% of infants below six months were breastfed exclusively in 2006; and the prevalence of continued breastfeeding up to two years old in Malaysia was 37.4% which is among the lowest compared to the prevalence in other countries in South East Asia. The role of health professionals in promoting and supporting breastfeeding has been increasingly emphasized. However, data on health professionals' perspectives on breastfeeding in Malaysia has been lacking. The aim of this study is to understand health professionals' perspectives on breastfeeding, their knowledge and attitudes towards breastfeeding and their self-efficacy in dealing with breastfeeding issues, as well as perceived barriers to providing support and issues around breastfeeding education.

METHOD: This research is a quantitative cross-sectional survey which investigates different aspects of community health professionals' (n=459) knowledge and attitudes towards breastfeeding, their self efficacy in dealing with breastfeeding issues and issues around breastfeeding education. Data collection will be carried out using a self-administered questionnaire which will be distributed to family physicians, medical officers, practice and public health nurses in selected public and maternal and child health clinics in Selangor. Analysis will be conducted with SPSS 22.0.

As no studies have previously been done in Malaysia evaluating breastfeeding knowledge and attitudes among health professionals, the result of this study could be used to establish a baseline for use in future assessments and will help measure the effectiveness of the activities of health education. It is hoped that this study will provide a greater understanding of professional support for breastfeeding, as such information would help identify areas for improvement around professional support for breastfeeding.

P-0454**Delayed childbearing for students: a hidden issue, dilemma, or real emotional problem?**

Pascal Collard¹, Claudia M. Van Der Heijde², Peter Vonk³, Frans J. Meijman⁴

¹Policy Analysis and Entrepreneurship in the Health and Life Sciences, VU University, Amsterdam, The Netherlands

²Student Health Services, Department of Research, Development and Prevention, University of Amsterdam, Amsterdam, the Netherlands

³Huisartsen Oude Turfmarkt and Student Health Services, General Practice, University of Amsterdam, Amsterdam, the Netherlands

⁴Department of general practice & elderly care medicine, VUmc School of Medical Sciences, VU University, Amsterdam, the Netherlands

Background and aim

From a survey in 1983 it appeared that ambivalence towards having children can lead to uncertainty, confusion and emotional distress among female university students. The aim of this study in 2013 was to measure if this ambivalence towards having children is changed in the time of thirty years, to find possible time trends and to determine indicators for general practitioners to detect internal conflicts (dilemmas or real emotional problems) regarding the desire to have children among female university students in order to provide effective care.

Method

We used a mixed methods design. Interviews with seven general practitioners, a literature search and the questionnaire used in 1983 were used to develop a new questionnaire. The newly developed questionnaire was distributed amongst female students through the Internet and a students' health service during spring 2013 (n =

398). We performed descriptive analyses and a logistic regression.

Results

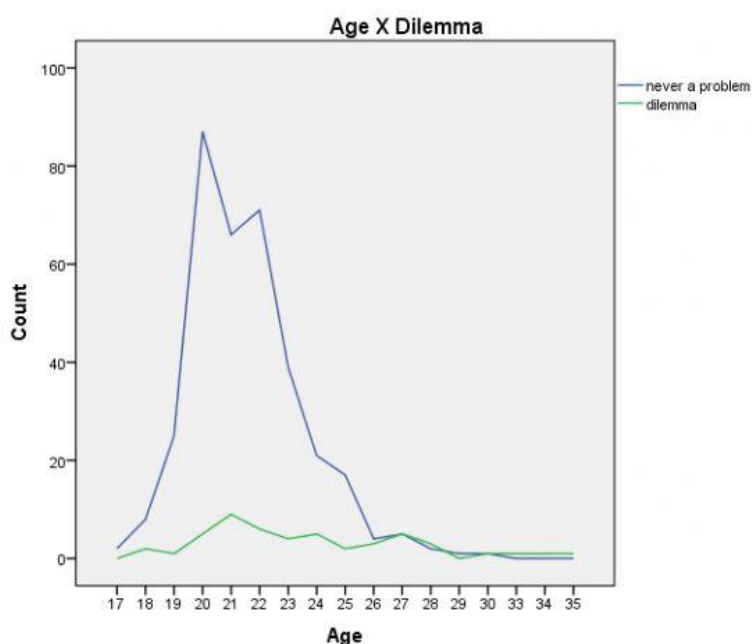

13% of the female students experienced being childless as problematic (2% often and 11% sometimes). From logistic regression analysis five factors showed significant associations with the internal conflicts concerning delayed childbearing: being older ($p=.057$), living together with a partner ($p=.080$), worrying (or worried) about fertility ($p=.003$), refusing abortion if pregnant ($p=.021$) and dissatisfaction with current contraceptive use ($p=.073$). GPs can use these factors as indicators in student patient consultations to detect dilemmas or real emotional problems.

Conclusions

Female students may experience being childless as a dilemma or even as a real problem in 2013. There was similarity in outcomes with the 1983 study. The factors correlating with the presence of a real problem or dilemma can be used by general practitioners as indicators that may prove useful to identify students with ambivalence towards delayed childbearing, in order to provide effective care.

Keywords: delayed childbearing, students, emotional well-being

Mothers knowledge and attitude towards routine childhood vaccination and additional vaccines

Nagehan Taştekin¹, Okcan Basat¹, Seda Geylani Güleç²

¹Department of Family Medicine, Gaziosmanpaşa Taksim Training and Research Hospital, Istanbul, Turkey

²Department of Pediatrics, Gaziosmanpaşa Taksim Training and Research Hospital, Istanbul, Turkey

Background and Aim

The aim of the study was to determine mothers' level of knowledge and attitude towards both groups of vaccines included in national immunization schedule and additional vaccines which are optional and are not a part of national schedule (Influenza, rotavirus and meningococcal vaccines).

Method

Our study was carried out between August-October 2014 on 181 mother who had 0-6 year old children admitted to Pediatric Outpatient Clinics of Taksim Gaziosmanpaşa Training and Research Hospital by interviewing with a questionnaire to evaluate their knowledge and behavior about childhood vaccination and their socio-demographic characteristics.

Results

71.8% of mothers were primary school graduate and above, 86.3% were low-middle income level. 96.7 percent of mothers considered that vaccination according to the ministry's national immunization schedule was necessary for their children.

80.7% of mothers were informed about vaccination by their family physician or nurse, other options were through media or a friend. 8.8% had not any information from any source. Scheduled timing of the first vaccination to newborn was answered correctly by 40.3% of mothers. When asked about side effects most of mothers mentioned about fever and local reaction at the injection area. 2.8% had no idea and 6% had fear about serious side effects such as anaphylaxis, neurologic impairment or death. 66.3 % had knowledge about additional vaccines. 28.7 percent of children received at least one additional vaccine. Rest of them had not received for these reasons: 14.4% financial problems, 28.7% lack of information, 28.7% believed that it was not necessary.

Conclusions

Even if many mothers were willing for vaccination they did not have adequate information about the vaccines not routinely administrated. Health care professionals have a very important role in education of mothers about immunization and disease prevention.

Birth outside the system: an exploratory study (study protocol)

Julia Suhaimi¹, Nur Amani Natasha Ahmad Tajuddin¹, Siti Nurkamilla Ramdzan¹, Ahmad Ihsan Abu Bakar¹, Khasnur Abdul Malek², Ilham Ameera Ismail², Punithavathy Shanmuganathan², Nurainulhana Shamsuddin³

¹Department of Primary Care Medicine, University of Malaya, Kuala Lumpur, Malaysia

²Discipline of Primary Care Medicine, Universiti Teknologi MARA (UiTM), Malaysia

³Department of Family Medicine, Universiti Putra Malaysia, Selangor, Malaysia

BACKGROUND:

Maternal mortality and morbidity is a critical and sensitive indicator for the state of any health system. The report on the confidential enquiries into maternal deaths in Malaysia in 2006-2008 has acknowledged that the need for the issue of home delivery being conducted by untrained / unqualified birth attendants to be seriously addressed. From 2006 – 2008 there were 23 maternal deaths associated with unassisted home deliveries. The recommendation in the reports includes the need to emphasis on proper risk assessment during the antenatal care and appropriate planning of high risk cases.

AIM:

This study is to explore the factors influencing mothers and their experience of 'birth outside the system', which is defined as giving birth outside the mainstream maternity care.

METHOD:

This is a qualitative study among pregnant women in Kuala Lumpur, Malaysia who are planning to give birth

outside the system and women who had experience giving birth outside the system. It will be done through in-depth interviews based on decision making framework developed by Murray-Davis (2012).

Expected RESULTS:

We expect to understand the ideas, concerns and expectations of women who chose to give birth outside the mainstream maternity care system. From the results of this study we hope to develop strategies to improve the healthcare delivery system and to reduce maternal and perinatal mortality caused by birth outside the system.

Family Physicians' Knowledge On Prenatal Care:Izmir/An Aspect From Turkey

Zeynep Ay¹, Huseyin Can¹, Melih Kaan Sozmen², Seckin Tosun Erdem³, Selami Dogan³, Handan Atsiz Sezik⁴

¹Family Medicine Clinic, Izmir Katip Celebi University Atatürk Training and Research Hospital, Izmir,Turkey

²Department of Public Health, Izmir Katip Celebi University, Izmir,Turkey

³Familiy Medicine Center, Izmir,Turkey

⁴Narlidere Public Health Center, Izmir,Turkey

Background and aim

About 800 women die from pregnancy or childbirth-related complications around the world every day. Almost all of these deaths could have been prevented by providing skilled care to pregnant women before, during and after childbirth. (1) In our study, we aimed to determine knowledge of family physicians (FP) on essentials of prenatal care.

Method

Our research included FPs who practice in İzmir between August-November 2104. Information obtained via questionnaire prepared by researchers based on current guidelines. Descriptive statistics are given as mean±standart deviation and percentage. Student t-tests, Mann Whitney-U tests and Chi-square tests were used to compare groups. P value <0.05 was taken as significant.

Results

Mean age of the respondents (n:225) ranged from 32-65 years old and mean age was 47.76±5.96. 34.2% (n:77) of FPs were women and 19.1% (n:43) were family medicine specialists. The mean duration of practice as a FP was 6.60±1.48 years and the average number of the pregnant women receiving prenatal care (PNC) was 21.18±11.03. All respondents stated that at least 4 PNC is necessary. Almost all FPs (97.8%) told that the first PNC visit should be before 14th gestational week. The majority of respondents knew main contents of physical examination (e.g. measuring weight and blood pressure, checking signs of anemia). Most FPs agreed to perform urine tests, haemoglobin, blood group typing and HbsAg. 92.9% of respondents knew when to start folate supplementation and 75.1% respondents knew when to start iron supplementation. Almost all respondents knew risk factors and danger sings.

Conclusions

All respondents know number and timing of PNC visits adequately. FPs have sufficient knowledge on examination and tests that can be done in primary care and danger signs. Continuing medical education and training programmes is essential to overcome lack of knowledge of FPs on tests unavailable in primary care.

OBJECTIVE: To determine the social trends in different age groups of adolescents between the ages of 11 to 20 by using "Fatih Social Trends Scale for 11-20 Age Version".

MATERIAL-METHODS: The "Fatih Social Trends Scale" questionnaire was applied to volunteer 585 adolescents. "Fatih Social Trends Scale" consists of 26 questions and 6 factors about social trends of adolescents. These participants average scores and general mean of total scores based on "Fatih Social Trends Scale" are calculated. Types of descriptive features such as the distribution of age groups in the study group analysis (number, percentage, mean and standard deviation) was revealed.

RESULTS: When the study group factor score averages were compared, it was seen that all factors are affected by "reading book regularly" like "social adaptation and status", "lack of drug abuse", "avoidance of violence", "school status", "family status", "targets and ideals". Also our findings indicate that "social adaptation and status" correlated to gender; "avoidance of violence" and "school status" correlated to age range and "family status" correlated with group of "exercising regularly".

CONCLUSION: "Fatih Social Trends Scale" scores of various factors shows that there are statistical differences between the "age groups". The findings by using previously developed psychosocial scale in this study can be used for developing beneficial applications for adolescents. Significant differences in the approaches puberty study results will be taken into account in this regard, which is thought to affect guidance services.

P-0459

Is folic acid 100% safe during pregnancy? New perspectives!

Susana Grilo Lourenço¹, David Rodrigues¹, Marta Lopes¹, Nídia Nunes¹, Teresa Pereira Leite²

¹USF Planície, ARS Alentejo, Évora, Portugal

²USF Alcoides, ARS Alentejo, Montemor-O-Novo, Portugal

Pregnancy is a period during which both baby's and mother's safety and well care are determinant. The pregnant woman's needs of energy and nutrients, such as: folic acid, iron, essential fatty acids and fiber, are higher than ever so it is recommended, apart from a rich diet, the intake of vitamin supplements. Folic acid reduces the risk of neural tube defects. The World Health Organization defends that a daily nutrition of 0,4 mg of folic acid during pregnancy should be initiated as early as possible.

Biographical research of clinical guidelines, systematic reviews and meta-analysis in English and Portuguese, published in the last 8 years, in Medline database employing the MeSH terms: "folic acid", "pregnancy" and "supplementation".

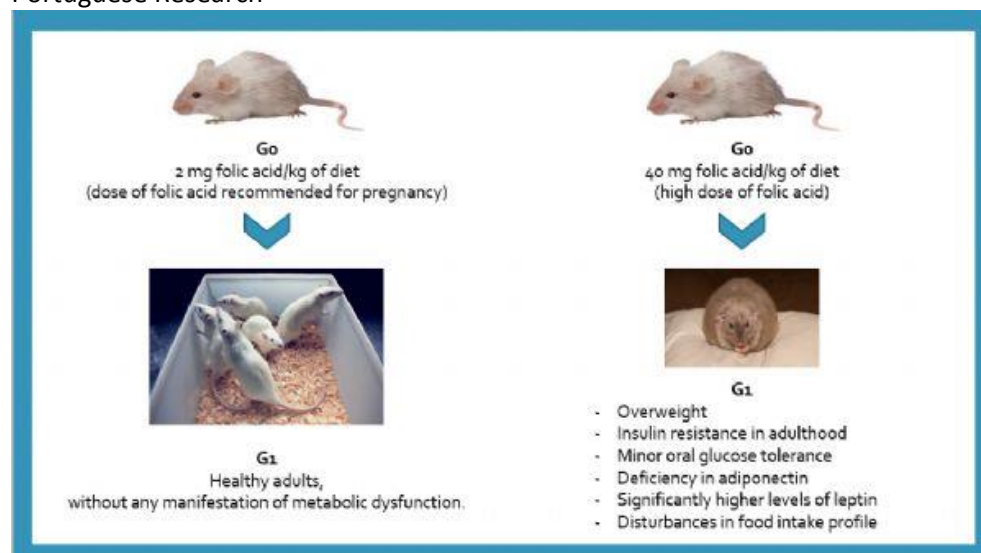

Few studies have looked at the safe upper limit of folic acid intake, even though pregnant women around the world are consuming increasingly high amounts of folic acid thanks to food fortification policies and widely available supplements and multivitamins. According to a portuguese research team from the Faculty of Medicine of the University of Oporto and the Catholic University of Portugal, the administration of 20 times of the recommended daily amount of folic acid in female rats throughout mating, the pregnancy period and lactation, results on baby rats who grew up to be overweight and insulin resistant in adulthood. The offspring also revealed to be deficient in adiponectin and they expressed food disorders. On the other hand, the female rats who's

consumed the recommended daily amount of folic acid had newborns who became healthy adults. In 2012 was published a revision in the British Journal of Nutrition "higher maternal folate status during pregnancy was associated positively with insulin resistance in 6 year old."

It is necessary to further investigate the mechanisms by which folic acid affects metabolism, finding the maximum recommended dose.

Carbonmonoxide exposure in pregnancy: a case report

Emel Kelestemur¹, Samet Uludag², Merve Canbaz², Irep Karatas Eray¹

¹Department of Family Medicine, Ataturk Training and Research Hospital, Bilkent, Ankara, Turkey

²Department of Family Medicine, Yildirim Beyazit University, Bilkent, Ankara, Turkey

Background and AIM: The most common Carbonmonoxide (CO) poisoning cases in developing countries are caused stove and water heater poisoning. The presence and detection of over 15% Carboxyhemoglobin (COHb) in the blood of pregnant woman results in feto-maternal morbidity and mortality. In our study, we discussed a case of CO poisoning in the week of 17 of the pregnancy and aim to emphasize the approach to CO poisoning in the pregnancy. **CASE:** A 21-year-old female (primigravid) at 17 weeks of gestation, applied our emergency service with complain of CO exposure from the water heater. When she arrived our emergency service, she did not lose consciousness and her vital signs were stable. In the obstetric ultrasound, a fetus is observed to have positive fetal heart rate, which is well matched with 17 weeks fetus. Maternal COHb was measured at 14.2% and oxygen therapy with a flow rate of 10lt/min was applied. Although hospitalization was suggested for the following up the complications, the patient left the hospital. **DISCUSSION:** CO gas causes toxicity with two-basic mechanisms. First, the competition between CO and oxygen for hemoglobin results in tissue-hypoxia. Second mechanism is the direct damage given by CO gas. The common clinical findings are headache, nausea, vomiting, blurred-eyesight, tachycardia, tachypnea, coma and death depending on the level of CO exposure. While maternal blood COHb level is lower than the toxicity levels, fetus can be damaged. Reference ranges for COHb should be lower than 5% for pregnant. For the COHb levels in the range of 5-15%, 100% oxygen therapy should be applied. For the COHb levels of 15% and above, hyperbaric oxygen therapy should be applied. **CONCLUSION:** In the case of CO poisoning suspect in pregnant, early diagnosis and appropriate treatment prevent the formation of maternal and fetal risks that can result in death.

P-0461**Knowledge, Attitudes and Practices of Mothers about Home Accidents**

Gizem Erdem¹, Emre Kocazeybek¹, Fatma Zehra Avşar¹, İsmail Dikmen¹, Oğuz Kaan Şimşek¹, Yasemin Çomak¹, Hayriye Kulbay Yüksel², Nurdan Yiğit¹, Tevfik Bayram¹, Dilsad Save¹

¹Marmara University, School of Medicine, Department of Public Health

²Turkish Ministry of Health, Family Health Center

Background&AIM:

The accident is defined suddenly and unplanned event which causes physical and psychological damage by World Health Organization. Particular group of children from 0-5 years of age constitute the most important group interms of home accidents. The aim of the study was to evaluate knowledge, attitude and practice of mothers who had 0-5 age years old children.

METHOD:

This survey as a descriptive study and carried out in Kartal Pendik Kaynarca Family Health Center Zümrütevler Family Health Center. The study population was consisted of the mothers who admitted to these centers. The sample of the study were randomly selected (n=122). Questionnaires were administered by face to face interviews. The results were obtained by applying the chi-square test with the mean percentage values. $p < 0.05$ was considered significant.

RESULTS:

Type of home accidents were identified as fall, shock, burns, drowning, poisoning. The most common type of accidents was falling by 68.9%. Mothers usually found not to take enough precautions against home accidents.

CONCLUSION:

Awareness of home accidents and knowledge about the preventive measures needs to be improved in the community.

Keywords: home accidents, knowledge attitude and practice, fall, health education, preventive medicine

P-0462**The knowledge and awareness of family physicians about the red reflex test during neonatal period**

Seda Coşkun, Selda Tekiner, Filiz Ak, Gülsen Ceyhun Peker

Department of Family Medicine, Ankara University School of Medicine, Ankara, Turkey

AIM: Eye problems during childhood can lead to irreversible vision issues when the diagnosis and treatment delays. During the neonatal period of well-child visit, the red reflex test is one of the priorities which should be included in family medicine training. The aim of this study is to determine the knowledge and the awareness of the family physicians about the red reflex test within the period of newborn in well-child follow up and the affecting factors.

METHOD: Between 1st February and 13th March 2015, a questionnaire consisting of 31 items was applied to the family medicine residents and specialists who were working both in training and research hospitals and university hospitals in Ankara. One hundred and fifty four family physicians participated in the study. The analysis was performed using SPSS version 11.5 and the data were evaluated by descriptive, univariate statistical analysis.

RESULTS: Mean age of the respondents was 30 years, 61% were female, 92.2% were residents, 7.8% were specialists. Of the family physicians 77.9% were working in training and research hospitals, 22.1% were in university hospitals. While 54 family physicians (35.1%) declared that they do routine eye screening examination during the neonatal period, 71% declared they don't. Of the doctors 26% told that they don't have any knowledge about eye screening examination, 19% told that she/he doesn't have an ophthalmoscope. Of the family physicians 85.7% had never heard the red reflex test. The family physicians who know the right timing of the first routine eye screening was 74%. Among the family physicians doing routine eye screening during newborn period, only 14.9% stated that they examined the red reflex test.

CONCLUSION: The knowledge and the awareness of red reflex test among family physicians is low. This issue must be given weight during residency and post graduate trainings.

An Appropriate Scale for Primary Health Care: Reliability and Validity of the Turkish Version of the Iowa Infant Feeding Attitude Scale

Nazmiye Kaçmaz Ersü¹, Abdurrahman Ersü¹, Pınar Köksal¹, Berna Erdoğan Mergen², Haluk Mergen¹, Kurtuluş Öngel³

¹Department of Family Medicine, İzmir Tepecik Training and Research Hospital, İzmir, Turkey

²İzmir Karabağlar Community Health Center, İzmir, Turkey

³Faculty of Medicine Head Department of Family Medicine, İzmir Katip Çelebi University, İzmir, Turkey

" AIM: The aim of this study is to describe reliability and validity of the Turkish version of the Iowa Infant Feeding Attitude Scale which was developed by De La Mora and colleagues.

MATERIAL-METHODS: This study was conducted with 209 mothers who have child under five years and who applied to İzmir Tepecik Education and Research Hospital. The translated IIFAS was administered to participants. Correlation analysis of total items have been done. Reliability of the scale is evaluated with Cronbach alpha coefficient. Statistical analysis is conducted using SPSS 16 and AMOS20.

RESULTS: Mean age of mothers was 30.2±5.48. 42.1% (n= 88) of mothers of children who were applied to outpatient clinics of pediatrics had primary school graduation, 24.9% (n=52) secondary school graduation and 8.6% (n=18) university or high school degree. 85.2% (n=178) of mothers didn't have any jobs.

Varimax rotation method was used for examination of factor structure of IIFAS. Result of Kaiser- Meyer- Olkin Measure of Sampling Adequacy test was found as 0.646. Result of Bartlett's Test of Sphericity was statistically significant (511, $p < 0.001$). Item-total correlation coefficient (rit) was 0.251.

Cronbach alpha coefficient calculated to detect internal reliability of the scale. Cronbach alpha internal reliability coefficient value was ($\alpha = 0.506$) before exclusion of items 8th and 17th. After exclude these items Cronbach alpha coefficient value was ($\alpha = 0.61$). χ^2/df value was 2.1 (< 5). This value was adequate for validity criterion.

CONCLUSION: Different scores of Cronbach alpha for IIFAS range with 0.46 and 0.86 for different countries. This result suggest that IIFAS gives different results for different cultures. Turkish version of IIFAS had intermediate reliability and accepted validity. Mothers attitudes for infant feeding is very important for primary health care. IIFAS is practical scale to evaluate mothers attitude for infant feeding in primary health care. "

Knowledge, attitude and behavior of the breastfeeding mothers about smoking

Burcu Aslan, Seval Yaprak, Cigdem Alkan, Rana Gundogan, Nilgun Ozcakar
Department of Family Medicine, Dokuz Eylul University, Izmir, Turkey

Background & AIM:

Using tobacco during the period of breastfeeding adversely affects the health of mother and child. American Academy of Pediatrics Committee on Drugs has stated that nicotine is contraindicated in nursing mothers. Using tobacco leads to decrease in mothers' milk production and children's weight gain. In present study, we aimed to determine the knowledge and attitude of mothers having babies between 6-24 months old about smoking, and their smoking behavior during breastfeeding.

Method

In our descriptive cross-sectional study, mothers admitted to Dokuz Eylul University Medical Faculty, Children's Polyclinic, were fulfilled a questionnaire developed by the researcher including questions about sociodemographic characteristics, knowledge, attitude and behaviors about smoking.

Results

Total 236 mothers with mean age of 29.73 ± 5.40 (Min=18, Max=46) were included in the study. Mothers had high educational level (41.1%). Most pregnancies were planned and desired (72.0%). Mean age of babies was 11.64 ± 5.12 months and 133 (56.4%) of them were female. Among mothers, 26 (11.0%) have never breastfeed, 105 (44.5%) were still doing and the other 105 (44.5%) were not currently doing. Smoking rates in pregnancy and lactation were 18.2% and 18.1, respectively. Smoking rate at the time of this study was 25.4%. Non-smoker fathers were 25.8%. Parents indicated that they are smoking near baby (3.8%). Among mothers, 99.6%, 97.0% and 69.1% were indicated that smoking near baby and during pregnancy is harmful and will cause gas pains, respectively. Most of mothers, who indicated smoking during the breastfeeding period is harmful, were not smoking in breastfeeding period ($p < 0.05$).

Conclusions

It was seen that most of mothers have knowledge about hazards of cigarette and pay attention to this during pregnancy and breastfeeding. However, percentage of mothers who smoke in this period is not low. Our study shows smoking behavior in pregnancy and breastfeeding period and in this context, we believe it will guide for further studies on this subject.

U-SHAPE – Ugandan Sexual Health and Pastoral Education

Emily Clark

Royal College of General Practitioners, UK

Background and Aim

Since 2013, we have been developing training in family planning for healthworkers, and in sex education for teachers, in Uganda. The project U-SHAPE (Ugandan Sexual Health and Pastoral Education) aims to disseminate positive messages about modern contraception in an attempt to dispel fears and misconceptions and address the high rate of unmet need for family planning.

Method: Our own published qualitative research and a local confidential enquiry of deaths, show that lack of access to and confidence in modern contraception is an important driver of the high rates of maternal and infant mortality. We have been awarded a THET partnership grant between RCGP and Bwindi Community Hospital, and are featured as a 'Success Story' on the WHO Family Planning training website.

Results: To date, we have trained more than a hundred health workers to a basic level, and 39 to a level equivalent to DFSRH. Our 'whole institution' approach to training has led to service developments including the screening for unmet need for contraception, with the target to reduce this from 40% to 20%. In addition, 50 primary school teachers meet quarterly for training to help reduce teenage pregnancies. We have looked carefully at the barriers to access, myths and cultural/ religious influences on family planning, and have used this to shape our training programs.

Conclusions: Our cascade model of training, involves training Ugandan USHAPE trainers with the aim of future scale up and long-term development. We have begun to role out the U-Shape training to similar hospitals across Uganda, such as Kisiizi Hospital.

Influenza vaccination uptake among Pregnant women during Flu season in a Rural Practice. Audit

Kandan Loganathan, Paddy Halligan, Gavin Maguire
Cottage Surgery, Bailieborough, Co.Cavan, Ireland

Influenza is responsible for significant morbidity and mortality in pregnant women. According to Health Service Executive(HSE) guidelines, all pregnant women should get influenza vaccine. We generated a list of all pregnant women during the 2013/2014 influenza season using Helix Practice Manager. We studied the consultation record, immunization record and maternity protocol for each patient, looking for documentation of discussion regarding influenza vaccination. Following the review, we had a practice discussion regarding changes that could be implemented to improve vaccination uptake. This included placing patient posters in the waiting room and at reception area, having the HSE vaccination leaflet displayed and placing reminder posters in all staff rooms. The practice nurses then initiated a system of messaging all eligible pregnant women to alert them that the influenza vaccine was available in the practice. The vaccination period started from October to end of April. All the data were recorded in an Excel spread sheet. There were 44 pregnant women eligible in the 2013/2014 group and 40 pregnant women in the 2014/2015 group. There was an almost equal mix between GMS and private patients. In 2013/2014, only 8 out of 44 pregnant women had influenza vaccine. Since the intervention was put in place, the uptake of influenza vaccine increased by 32 % in the 2014/2015. With regards to documentation rate, there was a 100% documentation rate in the 2014/2015 as compared to 9% in the 2013/2014 season which was a very significant improvement. There was a 32 % increase in influenza vaccination uptake since the introduction of posters, reminders and online messaging system. This uptake is inline with the international standards. There were also better documentation record between doctor and patient. The audit showed that even relatively simple, low cost interventions can produce an increase in vaccination uptake among this patient cohort.

Effects of Different Anesthesia Protocols on Lactation in the Postpartum Period

Leyla Kutlucan¹, Ilknur Suidiye Seker², Yavuz Demiraran², Ozlem Ersoy², Ibrahim Karagoz², Gulbin Sezen², Seyit Ali Kose³

¹Konya Training and Research Hospital, Department of Anesthesiology, Konya, Turkey

²Department of Anesthesiology, Düzce University Faculty of Medicine, Düzce, Turkey

³Department of Obstetrics and Gynecology, Düzce University Faculty of Medicine, Düzce, Turkey

Background & AIM: Breast milk has many features reinforcing newborn development, and as a nutrient, it is superior to all artificial nutrients. Breastfeeding is given great value in the healthy development of a newborn. In our study, we aimed to compare the lactation process by mothers who underwent elective cesarean section under general anesthesia, spinal anesthesia, epidural anesthesia, and normal vaginal birth.

METHOD: We compared the lactation process by mothers who underwent elective cesarean section under general anesthesia, spinal anesthesia, epidural anesthesia, and normal birth; 84 patients between 18-40 years of age with a risk of ASA I-II were included. Randomly patients were divided into four groups: group G (general anesthesia, n:21), group S (spinal anesthesia, n:21), group E (epidural an-esthesia, n:21), and group V (vaginal birth, without anesthesia, n:21). Oxytocin and prolactin values of all patients before and after operation or birth were recorded. In addition the initiation time of lactation after delivery or cesarean section were recorded.

RESULTS: In all groups, there were no significant differences among hormone levels in the prepartum period ($p=0.350$). Prolactin levels in group G ($p=0.011$) and oxytocin levels in group V ($p=0.012$) in the postpartum period were significantly higher than in the other groups. The start of lactation was significantly delayed in group G ($p=0.003$).

CONCLUSION: We consider that the onset time of lactation is delayed in patients undergoing cesarean section with general anesthesia when compared with patients who undergo cesarean section with spinal and epidural anesthesia and with patients who undergo normal vaginal birth. Because of the delay of awakening and recovery of cognitive functions in general anesthesia, communication between the mother and the newborn is delayed and so is the lactation.

Parents' Knowledge, Attitudes and Beliefs of Childhood Fever Management

Cenk Aypak¹, Esra Durmuş¹, Adnan Yüce², Hülya Yıkılkan¹, Derya İren Akbıyık¹, Süleyman Görpelioğlu¹

¹Department of Family Medicine, Dışkapı Yıldırım Beyazıt Training and Research Hospital

²Department of Pediatrics, Dışkapı Yıldırım Beyazıt Training and Research Hospital

Background & AIM: Fever is the most common cause for a child to be taken to the doctor. Studies report that parents have false beliefs and limited knowledge regarding fever, its management, and its role in illness. The aims of this study were to investigate parents' attitudes towards fever in their children and the common fears related to it

METHOD: We interviewed 206 parents, whose children attended the pediatric outpatient clinics of Dışkapı Yıldırım Beyazıt Training and Research Hospital, using an structured questionnaire, in April and May 2015.

RESULTS: Parents of lower educational level are more likely to take their febrile children to the hospital as soon as fever is detected and also tend to administer antipyretics at a lower temperature and take more often inappropriate measures apart from antipyretics (eg sponge the child with vinegar). Approximately half the parents believed that combining two medications is more beneficial. The most frequent harmful effect of fever reported by parents is brain damage, followed by seizures. About half of parents based decides on medication or dose on prior advice from the clinician, which might not be safe given the fever causes and fluctuations in weight over time.

CONCLUSIONS: Our results indicate that parents often misuse the antipyretics medications, incorrectly manage their child's fever, follow inappropriate practices to reduce fever, and generally have poor knowledge of basic information regarding fever. Findings from this study underscore the need to develop and evaluate programs that

educate parents and provide them with the knowledge base required to better manage their children's fevers.

Comparison of Diagnostic Strategies in Gestational Diabetes Mellitus

Serhat Purcu¹, Meral Mert², Sami Hatipoglu³, Murat Ekin⁴, Yildiz Okuturlar⁵

¹Department of Family Medicine, Bakirkoy Dr. Sadi Konuk Research and Training Hospital, Istanbul, Turkey

²Department of Endocrinology and Metabolism, Bakirkoy Dr. Sadi Konuk Research and Training Hospital, Istanbul, Turkey

³Department of Pediatrics, Bakirkoy Dr. Sadi Konuk Research and Training Hospital, Istanbul, Turkey

⁴Department of Obstetrics and Gynecology, Bakirkoy Dr. Sadi Konuk Research and Training Hospital, Istanbul, Turkey

⁵Department of Internal Medicine, Bakirkoy Dr. Sadi Konuk Research and Training Hospital, Istanbul, Turkey

BACKGROUND: Gestational Diabetes Mellitus (GDM) incidence is between %1-14 in different societies. GDM carries risks for the mother and neonate. In diagnosis, one of two different strategies is being applied to the women at 24–28 weeks of gestation. Of these two strategies, the first one is the two step 50 gram Screening Test in which following it, 100 gram glucose tolerance test (GTT) is applied to the women whose blood glucose is 140mg/dl or over; the other one is the strategy in which 75 gram GTT is applied without first applying scanning test first. We aim to compare these two strategy.

METHOD: The scanning results of the all pregnant women with an alive pregnancy during 24-28 weeks were evaluated retrospectively, having applied for routine pregnancy tracking between January 2012 and January 2013, whose Gestational Diabetic screening have been done. 936 pregnant women screened. Two step test strategy was applied to 576 of them and one step was applied to the rest 337.

RESULTS: In the two step strategy, of all the 576 pregnant women, %63.4 were negative and %36.6 were positive. The ones with a positive result were called for 100 gram GTT application. In the outcome of 50 gram, 211 women were positive but 50 of these didn't show up. In the outcome of 100 gram fasting, 116 people (%72) were negative and 45 people (%28) were positive. The rate of people with a diagnosis of GDM via two step method was detected as %17.2; the rate was %54 via one step strategy, 75 gram GTT.

CONCLUSIONS: We detected that 75 gram GTT one step strategy diagnosed GDM in a much greater rate. It can be mentioned that one step test strategy is much more sensitive to the two step strategy but increases the costs of treatment.

P-0470**Evaluating The Service Provided To Pregnant Women At Family Health Centers During Pregnancy**

Celal Kuş¹, Hamit Sırrı Keten², Nagihan Sarı², Hüseyin Üçer², Önder Ercan³

¹Department of Family Medicine, Medical Faculty, Kahramanmaraş Sutcu Imam University, Kahramanmaraş, Turkey

²Department of Family Medicine, Kurtul Family Health Center, Kahramanmaraş, Turkey

³Department of Gynecology and Obstetrics, Medical Faculty, Kahramanmaraş Sutcu Imam University, Kahramanmaraş, Turkey

BACKGROUND: The present study aims to evaluate the service provided to pregnant women at family health centers during pregnancy.

METHOD: The present study included pregnant women presenting at Kahramanmaraş Sutcu Imam University Medical Faculty Hospital Gynecology Polyclinics between 09.04.2015 and 19.05.2015. Pregnant women were informed prior to the study and 150 pregnant women giving consent were included in the study.

RESULTS: The mean age of the pregnant women included in the study was 28.50 ± 6.19 (min=18, max=42) years. The mean gestational week was 32.47 ± 8.88 (min=4, max=41) weeks. The educational status was secondary school and below in 94 (62.7%) participants, and high school and above in 56 (37.3%) participants. 58 (38.7%) women stated that they had pregnancy diagnosis at a family health center. 126 (84.0%) women stated that they knew the family physician and 116 (77.3%) women stated that they knew the family health personnel (nurse or delivery nurse). 26 (17.3%) participants stated that they had consultancy service before pregnancy compared to 124 (82.7%) participants stating that they did not. 109 (72.7%) pregnant women stated that they regularly went to the family physician during pregnancy, whereas 41 (27.3%) pregnant women stated that they did not. There were 95 (63.3%) participants agreeing and 23 (15.3%) participants disagreeing with the proposition of 'I think the family physician has sufficient knowledge about diagnosis and treatment', and 32 (21.3%) participants with no idea. Additionally, 115 (76.7%) participants stated that they had trust in family physician regarding pregnancy follow-up compared to 35 (23.3%) participants stating no trust.

CONCLUSION: The present study found that a small portion of pregnant women received consultancy service before pregnancy. It was also found that pregnancy women did not benefit from family health centers sufficiently during their pregnancy.

P-0471**The comparison of the vitamin d levels between the pregnant women with gestational diabetes mellitus and the pregnant women with normal glucose tolerance test results**

Selma Pekgör¹, Mustafa Başaran², Fatma Gökşin Cihan³, Orkide Kutlu⁴

¹Konya Training and Research Hospital, Family Medicine, Konya, Turkey

²Konya Training and Research Hospital, Gynecology and obstetrics, Turkey

³Necmettin Erbakan University, Meram Medical Faculty, Family Medicine, Konya, Turkey

⁴Konya Training and Research Hospital, Internal Medicine, Konya, Turkey

AIM: Gestational diabetes mellitus (GDM) is defined as β cell dysfunction and insulin resistance developed during pregnancy or first time diagnosed in pregnancy. There are conflicting results in the literature about the role of vitamin D in the development of the gestational diabetes mellitus and insulin resistance. This study aims to determine the vitamin D status of pregnant women with GDM and evaluate the relationship between 25(OH)D3 and GDM.

MATERIALS-METHODS: The pregnant women screened for GDM between 24.-28. gestational weeks at Konya Education and Research Hospital Gynecology and Obstetrics Clinics were included in that prospective cross-sectional study. The age, weight, and height, BMI, the history of disease and surgery, vitamin D level, multivitamin, and a history of drug use, use of scarf, exercise status, and family history of diabetes were recorded. As study parameters, 50 g glucose screening and 100 g OGTT were performed to the pregnant women between 24.-28. gestational weeks. Serum 25(OH)D3 levels of ≤ 10 ng/ml, 10-29 ng/ml and ≥ 30 ng/ml are

considered, vitamin D insufficiency and adequate vitamin D, respectively.

FINDINGS: Vitamin D deficiency and vitamin D insufficiency rates were found as 70% and 30% respectively. The 25(OH)D3 levels of pregnant women with GDM and NGT were similar (9.40 ± 3.53 ng/ml versus 8.00 ± 3.11 ng/ml). In terms of vitamin D deficiency, there was no statistically significant difference between the GDM and control group.

CONCLUSION: Recautions for the prevention of vitamin D deficiency in pregnant women should be increased and vitamin D supplements should be used in an effective way. Rates of vitamin D deficiency in women with GDM were similar to control group. We believe that, to demonstrate the role of vitamin D deficiency in the development of GDM; more extensive, prospective, and randomized controlled trials are needed.

Frequency and concerning factors on term infants with anemia whom registered on our family health center

Neslihan Erkuran¹, Sebahat Gucuk², Selami Kara³

¹Golyuzu 1st care center, Bolu,Turkey

²Department of Family Medicine, Abant Izzet Baysal University, Bolu, Turkey

³Bahcelievler 1st care center, Bolu,Turkey

BACKGROUND & AIM: In our study, Determination of the factors affecting anemia status of the infants followed by our family health center were intended.

METHOD: Reports of the infant subjects whom registered to our office between dates of January-May 2015 were investigated retrospectively Subjects with neonatally intervened medical history, empirical tracking file and information since the pregnancy of related mother were excluded from the research. 162 infants were selected according to our sampling criteria. Information about duration and last control on 9th month of pregnancy was recorded. The HB level of the mother were derived from the last HB level determined on the control attained in the last trimester of the pregnancy. Infants with Hb levels < 11.0 g/dl were accepted as anemic.

RESULT: The ages of 83 male (%51,2), 79 female (%48,8) of total 162 infant were differed between 9-24 month according to their birth certificates. %62,3 (n:101) of the infants were fed with only human breast milk till the transition period through supplementary food. The level of Hb on the sampling group whom fed with only human breast milk was significantly higher (p:0.013). the Hb value of the %37,7 (n:61) of the infants were detected under11 gr/dl. The Hb value tested on last examination were found to be statistically significant between mother and infant (p:0.01). Ratio of Hb value over 11 gr/dl was significantly high in infants taking iron supplement almost each day.

CONCLUSIONS: In our study, we have determined that Hb values of the mother measured during the pregnancy controls affect Hb values of the infant and that Hb values of the infant get better upon the regular intake of breast milk and iron supplement recommended by the ministry of health and this is important as it indicates the significance of regular pregnant-infant controls and iron prophylaxis.

Mothers' Information and Applications About High Fever

Yasemin Korkut, Muhammed Sefa Acar

Department of Family Medicine, Dumlupınar University, Kütahya, Turkey

AIM: This study has been conducted in order to determine the idea, knowledge and application of mothers having children about high fever.

METHOD: The study was carried out with 112 mothers who had a child and who were admitted to the family medicine policlinic of Dumlupınar University Hospital, in a two month period. Data was collected using a questionnaire form that included multiple choiced questions; (the results were) evaluated using the number, percentage and chi-square tests.

RESULTS:

28 of the mothers (25% of the participants) expressed that they did not know the limits of high fever. 65 of them (72,8%) regarded 38C and more body temperature as high fever.

14 mothers (15,6%) said that it was not necessary to lower the rising fever. 74 mothers said that high fever harmful for their children. 83 mothers were afraid of and anxious about their children when they had high fever. When the level of education increases, the fear of fever decreases.

As a first aid, 35 mothers (39,2%) took off children's clothes and made them have a shower with warm water. 7 mothers used antipyretics without consulting doctor.

Although 73 participants (81,8%) had a thermometer, 53 mothers checked fever by touching and 13 mothers (14%) checked by looking at overall situation of their children, only 33 mothers was using a thermometer. 25 mothers mentioned that they didn't know how to use thermometers. 17% of the mothers knowing how to use mentioned the amount of the time less than they had to keep the thermometer. 29% of the mothers mentioned more time than required time. While checking temperature, 81,2% preferred armpit. It was observed that 89,1% had antipyretics at their home and 56% preferred paracetamols.

CONCLUSIONS:

As a result of statistical analysis, a meaningful relation has been found out between the age and education levels of mothers consider high fever as dangerous.

However, their information and applications about high fever are inadequate and wrong.

Keywords: Fever, Child with high fever, Mothers' information and applications.

Pregnants' Nutritional Knowledge Levels and Folic Acid Use Attitude in Ondokuz Mayıs University Department of Gynecology and Obstetrics

Aysenur Alper Gurz¹, Fusun Artiran Igde¹, Emel Kurtoglu², Mustafa Fevzi Dikici¹, Fusun Yaris¹

¹Department of Family Medicine, Ondokuz Mayıs University, Samsun, Turkey

²Department of Gynecology and Obstetrics, Ondokuz Mayıs University, Samsun, Turkey

AIM: Pregnancy is one of the most important period in life increasing micronutrients, and macronutrients needs of the body; both for the health and well-being of the mother, growing fetus and the newborn. Folic acid supply in the preconceptional period and the first trimester can reduce the incidence of neural tube defects (NTDs). It has been shown that prenatal multivitamin supplementation is associated with a decrease in several congenital anomalies and a decreased risk for pediatric brain tumors. This study aimed to evaluate the relationship between nutritional knowledge and the use of folic acid during pregnancy.

METHODS: A questionnaire was administered to 102 pregnant women attending to Ondokuz Mayıs University Department of Obstetrics and Gynecology between February and May 2014. The inquiry form included the demographic properties such as the women's age, number of parity, educational degree and socioeconomic status. We also asked whether their pregnancy was planned or not, where do they get information about the use of folic acid.

RESULTS: The mean age was 29,7±5,5. 41.4% of pregnant women were primigravida and 58.6% of them were multiparous

women. According to the statement of pregnant women 19.6% of them were intermediate, 56.9% bad and 23.5% were good socioeconomic status. Seventy-six women (74.5%) planned their pregnancy. 41.3% of the women had started folic acid in the preconceptional period and continued it during their first trimester. 84,3% of pregnancies using folic acid was most initiated by doctors.

CONCLUSIONS: It is regarded that the frequency use of folic acid is positively correlated with socioeconomic status and education of the pregnant women. Because of the low socioeconomic status and lack of education generally, women who are in the fertile period should be informed about the role of nutrition and especially folic acid use for preventing NTD's.

A Retrospective Analysis of Demographic Characteristics for Adolescent Pregnancies

Hande Ileri¹, Alper Ileri², Mehmet Özeren³, Kurtuluş Öngel⁴

¹Clinic of Family Medicine, Tepecik Training and Research Hospital, Izmir, Turkey

²Clinic of Gynecology and Obstetrics, Buca Gynecology and Obstetrics and Pediatric Hospital, Izmir, Turkey

³Clinic of Obstetric and Gynecology, Tepecik Training and Research Hospital, Izmir, Turkey

⁴Department of Family Medicine, Izmir Katip Çelebi University, Izmir, Turkey

BACKGROUND & AIM: Adolescent pregnancy is one of the major health problems worldwide. Adolescent pregnancies are high-risk pregnancies in terms of maternal and fetal. In the study; it was aimed to assess maternal demographic characteristics in adolescent pregnancy.

METHODS: Pregnancy and birth records of both under 18 year old and over 18 year old pregnant, who gave single and alive birth over 20 months at the same period and were referred to Izmir Tepecik Training and Research Hospital between 01.06.2009-01.06.2014, were retrospectively examined. Demographic characteristics of groups; age, gravida, parity, having a civil marriage with the partner, kinship with the partner, antenatal care, use of substances are compared. For the statistical significance of results, p value was <0.05.

RESULTS: There were 282 participants in the adolescent group, 340 participants in the non-adolescent group. The average rate of age was 16.4 for adolescent group, 26.1 for non-adolescent group(p<0.05). When the counts of gravidity and parity average rates; in adolescent group, the gravidity average rate was 1.2 and parity was 0.1; in non-adolescent group, the gravidity average rate was 2.3 and parity was 0.9(p<0.05). There was civil marriage between partners for 9.6% of women in adolescent group and % 99.1 of women in non-adolescent group(p<0.05). 7.8% of women in adolescent group and 4% of women in non-adolescent group are relatives with their partners(p<0.05). 29.8% of the adolescent and %85.6 of the non-adolescent cases had antenatal care(p<0.05). In the adolescent group; rate of substance use was 2.5%, while in the control group it was %3.4(p>0.05).

CONCLUSIONS: Pregnant adolescents have higher risk for negative maternal and fetal outcomes. Furthermore study results reported that inadequate use of antenatal care services is more common in adolescent pregnant. Health care providers have to be alert about prevention, ensuring antenatal care in case of detecting adolescent pregnancies.

Birth Defects in A Safety Net Hospital 2005-2013: Incidence, Determinants and Plausible Environmental Factors

Josephine Rebecca Fowler

Office of Academic Affairs & Department of Family Medicine, JPS Health Network, Fort Worth, TX USA

Birth Defects in a Safety Net Hospital 2005-2013: Incidence, Types, Determinants and Plausible Environmental Factors

Introduction

Birth defects are the number one cause of infant deaths annually. Approximately 1 in 33 infants are diagnosed with a birth defect in the United States. Birth defects occur in 4 percent of births in high income countries and 8 percent of low income countries. Financial costs as a result of the birth defect are estimated to be \$2.6 billion annually. Approximately 50% of the causes of birth defects are unknown. Chromosomal abnormalities are found in more than half of embryos miscarried in the first trimester. A pregnancy with a genetic problem has a 95% probability of ending in miscarriage. Environmental factors commonly named as teratogens may impact birth defects spontaneously or require genetic and environmental interactions. This study looks at potential correlations based on maternal history.

Methods

Retrospective exposure cohort, Observational study. A cohort of births from 2005 through 2013 were selected for evaluation of correlates to birth defects based on information in maternal records. Variables collected included zip codes of residence. Secondary geographic mapping and data was used to assess plausible risk associated with environmental factors.

Results

Incidence data is presented and compared to state and national incidence of birth defects. The county incidence is twice that of the state and nation. Cardiac anomalies accounted for the highest incidence of the congenital anomalies in this cohort.

Conclusions

There are variations in incidence of birth defects in geographic regions. Causation is multifactorial making it difficult to link causation to any specific agent. Reviewing both known and plausible risk factors and secondary data proves to be a potential method to further understand preventable risk.

Why They Give Up Breastfeeding So Early? A qualitative study from Turkey

Naciye Irmak, Burcu Başaran, Esmâ Özçelik, Arzu Uzuner

Marmara university family medicine department, Istanbul, Turkey

BACKGROUND:

According to the World Health Organization mothers are advised to breastfeed their babies for a total of six months without giving any other food even water which means "Exclusive Breastfeeding" (EB). Despite the "Baby Friendly Initiative" of Turkish Ministry of Health, mothers give up breastfeeding before six months.

AIM: The purpose of this study was to determine the reasons for giving up breastfeeding and early weaning.

Materials METHODS:

This is a qualitative study. Recently delivered mothers who participated in an on going randomized controlled intervention study on breastfeeding and who gave up breastfeeding were invited by phone call for a semi-structured interview in the Family Medicine Department of Marmara University Medical School. Mothers have been asked in dept about the reasons for early weaning. All the interviews were recorded and tape transcripts were analyzed thematically by four researchers.

RESULTS: A total of 57 women were called by phone; 27 mothers who accepted the interview were recruited in the study. The mean age of group 29.3 ± 5.6 years, 88.9% of mothers were housewife, two mothers were illiterate, 10 mothers were elementary school graduated, 9 mothers were high school or university graduated. Main question was about "one's reasons for early weaning". Three themes were found out: 1-The reasons for giving up

breastfeeding; 2-Mothers perceptions; 3- External effects. The main codes for early weaning were: medication use of mother and the baby; hospitalization; stress; baby's health problems; mother's prior breast feeding experiences; baby bottle use and the baby's deny for breast milk. Mothers' perceptions were mostly about the baby satiety. The external effects were that of the health personel and of the family.
CONCLUSION: The time spent in the hospital following delivery and the mothers' perceptions about the satiety of the baby and baby's health problems are the most prominent reasons for early weaning.

Keywords: give up breastfeeding, barriers to breastfeeding, mother's perceptions during breastfeeding

Table 1. Demographic profiles of mothers

Table 2. Demographic profiles of mothers		
Age	Number	Percent(%)
20-25	9	33,3
26-31	9	33,4
32-37	9	33,3
Total	27	100,0
Maternal education(years)	Number	Percent(%)
0-8	18	69,2
9-12	4	15,4
>12	4	15,4
Total	26	100,0
Maternal work	Number	Percent(%)
Housewife	24	88,9
Working mother	3	11,1
Total	27	100,0

Table 2. Themes

Theme 1: Mothers perceptions	
Code 1	Negative perception about baby's satiety and/or being hungry. "...my baby is always crying, so that I think she is hungry..."
Code 2	Negative perception about baby's grow up "...I always think my baby is smaller than the other babies..."
Code 3	Neonatal jaundice occurrence due to the insufficiency of breast milk "... because of my baby didn't suck enough he became neonatal jaundice; so I started baby food..."
Code 4	Belief about insufficiency of her breast milk depending on the past experiences "...this is my fourth delivery, my breastfeeding was enough only for 10 days to my babies..."
Theme 2: External factors that influence breastfeeding	
Code 1	Family's effect (husband, mother-in-law) "...I had problems with my husband, we had divorced so my breast milk went dry..." "...my mother in law persisted me to breastfeeding my baby, so I got angry with her and gave up breastfeeding..."
Code 2	Health worker's (doctor, nurse) decision "...the doctor said this baby was hungry, so that I started baby formula..."
Code 3	Using baby bottle "...my breast milk was absent at night, I was giving formula using baby bottle then she get on with this and she didn't want breastfeeding..."
Theme 3: Health status	
Code 1	Hospitalization of the mother and the baby "...my baby stayed at incubator, so I couldn't breastfeed her..."
Code 2	Medication of the mother and the baby "...because of my rheumatism I had to use drug so I couldn't breastfeed..."
Code 3	Mother's health
3a	Cesarean section "...I had cesarean section so that my breast milk was insufficient..."
Code 4	Baby's health
4a	Infantile colic "...because of infantile colic my baby became restless, when I gave formula he slept well..."
4b	Restlessness of the baby "...my baby always had restlessness, he cried all the time so I gave formula then he calmed down..."

Using OCS and Unobserved 37 Weeks of Pregnancy: A Case Report

Merve Taştan¹, Gökçe Nur Gök¹, Derya Önal¹, Gamze Ersen¹, İrfan Şencan¹, İsmail Kasım¹, Rabia Kahveci¹, Cemal Reşat Atalay², Adem Özkara³

¹Ankara Numune Training and Research Hospital Department of Family Medicine

²Ankara Numune Training and Research Hospital Department Gynecology and Obstetric

³Hitit University Department of Family Medicine

INTRODUCTION:

Today one of the contraceptive methods is using OCS(oral contraceptive). OCS is used by world 8,9% and in Turkey 4,6% (1,2). Unwanted pregnancies could be prevented 99.7% with OCS. The protection is reduced to 92% with irregular use(3). However, despite the regular use of OCS pregnancy can happen so we present the case to draw attention to this topic.

CASE:

Thirty-five-year-old female patient was admitted to the clinic with complaints of abdominal distention. In her medical history the patient has 15 days as of this complaint without diarrhea, constipation and abdominal pain. The patient did not have any chronic diseases. In the last 6 months patient has recurrent vaginitis, urinary tract infection and many times received antibiotic treatment. It was learned that in 2.5 years OCS use as a contraceptive method.

At her gynecological examination collum is multiparous and has lovere. We detected intrauterine pregnancy at 37 weeks with USG. Non-stress test was reactive. The patient can't feel fetal movement.

The blood tests results are iron deficiency anemia and vitamin B12 deficiency. Urinalysis RESULTS: WBC: 22 (0-5 at each site). No growth in urine culture. Candida albicans growth in the vagina culture.

The patient uses OCS and prenatal testings weren't closely monitored gave birth with C/S at 39 weeks. Baby has 8-9 APGAR.

CONCLUSION:

In this case we wish to draw attention to woman in reproductive period who use OCS regularly and menstruate regularly become pregnant with % 0,3 risk and like our case may be can't notice pregnancy even has pregnancy experience. In this context, We must inform sexually active patients who use of contraceptive methods right about they can pregnant.

Urinary Incontinence Among Pregnant in Zonguldak Region of Turkey

Nejat Demircan¹, Ülkü Özmen², Hamdi Küçük³, Firuzan Köktürk⁴

¹Department of Family Medicine, Bülent Ecevit University, Zonguldak, Turkey

²Department of Obstetrics and Gynecology

³Department of Family Medicine

⁴Department of Biostatistics

AIM: Urinary incontinence (UI) is a worldwide health trouble and common in pregnancy. It could effect the quality of life. The present study was conducted to determine its prevalence, effect on quality of life and its etiologic features among 132 pregnant women.

METHOD: ICIQ-SF and Wagner's quality of life scale were used in collecting data and SPSS in statistical analysis.

RESULTS: 56 out of 132 (42.42%) declared presence of urinary incontinence. There was statistical difference between effect of frequency of urinary leakage and QOL scores ($p=0.022$; < 0.05) and also between the amount of leakage and QOL scores ($p=0.01 < 0.05$).

The frequency, amount of UI can be seen in table 3. In summary, 19 pregnant women (33.93%) admitted to having urinary leakage once a week or less, while 8 women did twice or three times a week (14.28%), 5 women did once a day, 14 women did few times a day and 8 declared always ($p=0.022$; < 0.05). The amount of leakage was generally "small" ($n: 35$; 62.5%) whereas 9 (16.07%) women admitted "moderate" amount. On the other, hand there was no participant admitted "large" amount of leakage ($p=0.01 < 0.05$).

CONCLUSION: It is required to give more attention on understanding the impact of UI on the quality of life in the pregnant and intimate relationship of health care givers on the issue.

⁴MEDICAL PARK DEPARTMENT OF FAMILY MEDICINE, IZMIR

⁵ATAKUM PUBLIC HEALTH CENTER, SAMSUN

Background and AIM: As the frequency of working mothers are increasing several families demand help of their grandparents as a babysitter. The families give this decision because of financial, social or safety problems which they are facing. The aim of this study is to investigate depression and quality of life among grandparent who are looking after their grandchildren.

MATERIAL-METHOD: The study is conducted by 64 volunteered family physicians in four different cities of Turkey (Izmir, Samsun, Amasya, Çanakkale). These physicians asked their enlisted population over the age of 65 to answer Beck Depression Inventory, EQ5 and General Health Score. The participants who look after their grandchildren as babysitter are accepted as study group and they filled a survey questioning the conditions how they look after their grandchild, what are their responsibilities, how much time daily they spent as a babysitter etc.

RESULTS: A total of 3101 participants included into the study (Study group n= 1190, 38.3%). The participants in the study group were younger (65.39±0.1 years) than the control group (72.03±0.1 years). The grand parents were mostly look after their grand children in daytime (74.9%), they spent 81.39±60.1 hour per week for babysitting. The participants in the study group had lower EQ5 scores (7.29±2.2) compared to control group (9.08±0.4) (t=20.128, p<0.001). The control group had lower general health scores (49.79±20.1) and higher BECK depression scores (22.25±13.7) compared with the study group (66.56±18.4) and (12.96±11.84) respectively (t=20.956, p<0.001 and t=19.305, p<0.001). There was correlation between age of the participants in study group with EQ5 (r=0.279), general health score (r=-0.432), and BECK (r=0,395) (p<0.001 respectively).

CONCLUSION: The grandparents had better scores for depression and general health scores although their quality of life is lower compared to the control group. More information is needed to explain this situation.

Gestational Thyrotoxicosis

Selçuk Yıldız¹, Yusuf Üstü², Ebru Yılmaz¹, Sevim Öğülmüş¹, Basri Furkan Dağcıoğlu², Mehmet Uğurlu²

¹Family Medicine, Ankara Atatürk Training and Research Hospital, Ankara, Turkey

²Family Medicine, Yıldırım Beyazıt University, Ankara, Turkey

BACKGROUND:

Aside from diabetes mellitus, hyperthyroidism is the most common endocrinopathy in pregnancy. Its prevalence is about 0.05 to 0.2%. In this case, we aim to evaluate obstetric outcomes of the women with thyroid dysfunction.

CASE:

A 31-year-old woman with 14 week twin pregnancy was admitted to obstetrics clinic because of the shortness of breath. Her physical examination was normal. Obstetric ultrasonography was consistent with her gestational week and there were no abnormalities on fetuses. The laboratory findings were revealed hyperthyroidism (TSH: 0,005 µIU/mL, T4: 2,4 ng/dL, T3: 9 pg/mL, Anti Thyroglobulin antibody: 31,24 IU/mL, Anti TPO antibody: 5,14 IU/mL) and elevated liver enzymes (AST: 71 U/L, ALT: 186 U/L). Close follow-up was recommended without medication because of possible complications.

At 18. week visit, laboratory analysis revealed normal liver function test but her thyroid function tests were still abnormal. At her 20. week visit she was diagnosed as intrauterine exitus and two dead fetuses with 500 gr and

560 gr in weight, delivered vaginally. In follow up, it was observed that her thyroid function tests were at normal levels. She was considered as gestational thyrotoxicosis and discharged.

DISCUSSION

Thyroid dysfunction in pregnant women may cause serious maternal and fetal complications. The cause of the symptoms associated with hyperthyroidism in pregnancy is the thyrotrophic effects of high levels of β -HCG. The upper normal range for TSH is recently considered to be 2.5 mUI/mL in the first trimester and 3.0 mUI/mL for the remainder of pregnancy.

The term gestational thyrotoxicosis refers to patients with clinical and biochemical hyperthyroidism in early pregnancy. Screening for TSH, which is a sensitive marker for thyroid dysfunction, should be supported despite lack of consensus among authors.

Keywords: pregnancy, Gestational Thyrotoxicosis, hyperthyroidism

Comparison of Edinburgh Postnatal Depression Scale and Patient Health Questionnaire to Screen Postpartum Depressive Symptoms among Mothers of 0-12-Month-Old Babies

Tuğba Yurdakul, Ayşe Gülsen Ceyhun Peker, Zehra Dağlı, Ayşe Selda Tekiner, Mehmet Urgan

Department of Family Medicine, School of Medicine, Ankara University, Ankara, Turkey

OBJECTIVE: The study was carried out to compare the Edinburgh Postnatal Depression Scale (EPDS) and the 9-Item Patient Health Questionnaire (PHQ-9) as a screening tool for postpartum depressive symptoms, to investigate the prevalence of depressive symptoms and to evaluate the risk factors of depressive symptoms among mothers of 0-1-year-old babies who applied to the well-child clinic.

METHODS: The cross-sectional study included 425 women who registered their 0- to 12-month-old infants at the well-child out-patient clinic of the Division of Social Paediatrics of a university hospital in Ankara between September and November, 2014. The participants completed a questionnaire designed by the researchers, containing demographic characteristics, EPDS, and PHQ-9. The data was analyzed by Student's t, Pearson's Chi-Square, Fisher's exact, and Mann Whitney U tests and logistic regression. Two scales were compared using intra-class correlation coefficient, Spearman's correlation, and inter-rater agreement.

RESULTS: The prevalence of postpartum depressive symptoms was 21.9% with EPDS. The proportion of women with increased risk for depression with PHQ-9 was 23.6%. History of depression, history of anxiety disorder, poor relationship between the participant and her partner, between the participant and her mother, between the participant and her partner's parents, an unplanned pregnancy, child care-related problems, and health problem of the child were the risk factors significantly associated with postpartum depressive symptoms. The predictors of postpartum depressive symptoms were poor relationship between the participant and her partner, between the participant and her mother, between the participant and her partner's parents. The agreement between EPDS and PHQ-9 was generally moderate with Inter-rater agreement ($\kappa=0.541$, $p<0.001$). There was a positive correlation between two scales. Both scales were similar for detecting high postpartum depression risk. Intra-class correlation coefficient between EPDS and PHQ-9 scores was excellent ($ICC=0.793$; $p<0.001$).

CONCLUSION: As EPDS, PHQ-9 can be used to screen postpartum depression in primary care.

Keywords: Postpartum depression, depression screening, Edinburgh Postnatal Depression Scale (EPDS), 9-Item Patient Health Questionnaire (PHQ-9)

Case report: Ovarian Hyperstimulation Syndrome (OHSS)

Mustafa Kürşat Şahin¹, Gülay Şahin²

¹Canik Community Health Center, Samsun, Turkey

²Department of Family Medicine, Medical Faculty, Ondokuz Mayıs University, Samsun, Turkey

Background & AIM: Ovarian hyperstimulation syndrome (OHSS) is a rare, iatrogenic complication for ovarian stimulation by assisted reproduction technology and other infertility treatments. Following gonadotropin therapy, OHSS usually develops several days after oocyte retrieval or assisted ovulation. This syndrome is characterized by ovarian enlargement due to multiple ovarian cysts and an acute fluid shift into the extravascular space. Young age, low body mass index, polycystic ovarian syndrome, previous OHSS, high follicle count, and elevated serum estradiol (E2) are the certain factors that predispose women to OHSS.

CASE: A 28-year-old nulliparous woman presented to family medicine clinic with complaints of severe abdominal pain and shortness of breath. The clinical picture showed abdominal pain, ascites, nausea, dyspnea and amenorrhea. After imaging examinations and laboratory tests, the diagnosis was established. Then patient referred to obstetrician. Twin pregnancy was in 12 weeks. Obstetrician performed USG. The ultrasonographic examination revealed bilaterally enlarged multicystic ovaries and a large amount of ascites. Immediately after admission, infusion therapy was started, consisting of normal saline-infusion 0.9% 1000 ml, glucose 5% 1000 ml. Body weight, abdominal circumference, intake and outputs, ultrasonography, and laboratory studies were monitored strictly daily. Then 1 week later, shortness of breath and abdominal pain decreased. Patient was discharged from hospital. After delivery all symptoms relief.

CONCLUSIONS: Diagnosis and management of ovarian hyperstimulation syndrome requires high index of suspicion, prompt investigation and early initiation of effective therapy. With correct diagnosis and early treatment, most patients recover.

Keywords: ovarian hyperstimulation syndrome, pregnancy, IVF

P-0484

Case report: Pruritic urticarial papules and plaques of pregnancy (PUPPP)

Mustafa Kürşat Şahin¹, Gülay Şahin²

¹Canik Community Health Center, Samsun, Turkey

²Department of Family Medicine, Medical Faculty, Ondokuz Mayıs University, Samsun, Turkey

Background & AIM: The eruption of changes occurs initially on the abdomen and extends over the thighs, legs, back, buttocks, arms, and breasts. Skin changes typical for PUPPP are erythematous, urticarial plaques, and papules. Rash regression is usually observed with in 6 weeks postpartum. PUPPP is a rare dermatosis of unknown etiology that is most frequently seen in primiparas and twin/multiple pregnancies. The prognosis is favorable. We report a case of PUPPP in a primipara and review the clinical signs, differential diagnosis, possible etiologic factors, diagnosis, and therapy.

CASE: A 29-year-old woman complained of an intensely pruritic rash for 2 days. The rash began 28-weeks during pregnancy. It began on her abdomen and spread to her buttocks, legs and upper arms. On examination, erythematous papules and urticarial plaques were present in the striae of the abdomen and buttocks and involved the legs, arms and back. No excoriations, vesicles or pustules were present, and there was sparing of the face, palms and soles. The patient was treated with desloratadine, hydroxyzine and cool compresses. Follow-up 4 days later revealed a worsening rash and persistence of severe pruritus. At that time the patient was placed on metilprednisolon and beklometasone dipropionate, which led to relief of her symptoms and clearing of the rash. After delivery all symptoms relief.

CONCLUSION: PUPPP's prognosis extremely good, but mother's severe itching is unbearable. Primary care physicians should be kept in mind.

Keywords: Pruritic urticarial papules and plaques of pregnancy, pregnancy, histamine antagonists, topical steroid

P-0485

Knowledge Level About Folic Acid and Its Usage Rate Among Pregnants

Ceyhun Yurtsever, Elif Altunbaş Ateş, Turan Set

Department of Family Medicine, Karadeniz Technical University, Trabzon, Turkey

AIM: This study aimed to determine knowledge level about folic acid (FA), its usage rate and factors affecting them in pregnant.

METHODS: This study was performed on the pregnancy clinic, Karadeniz Technical University, Faculty of Medicine in January 2015 as a cross-sectional study. A questionnaire asking patients' demographic characteristics, knowledge level about folic acid and its usage was developed by researchers. This survey was performed in 102 pregnant volunteers.

RESULTS: The mean age of participants was 30.6±6.1 years. The rate of pregnant who know preventive effect of FA on congenital abnormalities was 42.2% (n=43). Approximately half of these women (48.8%) had learned it from a gynecologist. When FA regular usage rate among participants was 63.7%, almost all of them (95.5%) had started to use it after learning her pregnancy. Usage rate of FA with advice from gynecologist and family physicians was respectively 87.1 % and 11.4%. Knowledge level about FA had increased with education level ($p<0.001$) and usage rate had increased with knowledge level about it ($p<0.001$). Age, total number of pregnancies, number of living children or abortion and abnormally birth history didn't affect the FA's usage ($p>0.05$).

DISCUSSION: In our study, knowledge level about FA and its usage rate was seen as low. The biggest part of pregnant started to use FA when they learn their pregnancy. This situation can attribute to inadequacy of pregnancy planning and prepregnancy care. Appropriate use of folic acid decreases the NTD about %75. In one study, the rate of using FA in pregnant who consult to primary care in order to prepregnancy care was determined 5 times more in comparison to all population.

CONCLUSION: FA usage of women who planned pregnancy is highly important within the context of preventive health service. Increasing of knowledge level about FA contribute to increase its usage rate.

Keywords: Family physician, folic acid, prepregnancy care

P-0486

Postpartum Period Shingles

Kamuran Bahar Sandıkcı¹, Funda Gökgöz Durmaz²

¹Çubuk 5th Family Health Center, Family Medicine, Ankara, Turkey

²Bağlar 13th Family Health Center, Family Medicine, Diyarbakır, Turkey

BACKGROUND: Postpartum woman (puerperium) refers to the women within about six weeks period after birth. During this period when hormonal, inflammatory and immune system changes reversed in women, care should be taken against infectious diseases.

METHODS: In this study, we present the diagnosis and treatment of a patient presenting with postpartum developed shingles.

RESULTS: A 31-year-old g1p1 postpartum woman on 26th day admitted to family medicine center with vesicular infection spreading along left C4 dermatome but not exceeding midline of the body (figure). She told that her complaints started 5 days ago with itching, first she had thought that it was acne and tried to drain it, and then she thought it was caused by her necklace and applied cologne. The lesions were observed as few groups had begun to dry. She stated that she have been going on lactating. General state of the baby was active, lively and no debris was observed. The patient was informed about her condition and recommended to continue lactation. She was warned to be careful about chickenpox which may be develop in the baby.

CONCLUSION: Problems experienced by mothers should be continuously assessed by health care personnel during 6 weeks, in order to ensure the quality of post partum follow-up and care

³Department of Periodontology, School of Dentistry, Saint-Joseph University, Beirut, Lebanon

⁴Department of Public Health, School of Medicine, Saint-Joseph University, Beirut, Lebanon

BACKGROUND AND AIM: The percentage of Lebanese elderly has increased considerably. Since they are marginalized in the health policy-making process, we suggest a strong social inequity of oral health that has not been studied so far.

The aim of our study was to compare the oral health in a Lebanese elderly group according to their socioeconomic status (SES).

METHODS: This was a cross-sectional designed study. Participants were recruited from three different primary health care clinics in Beirut: two private clinics where patients pay for medical fees or are covered by a health insurance, and a central dispensary for elderly where persons with no health insurance can have free medical consultations. During a six-month period, all patients aged 65 years or more and living independently were invited to participate in the study. Data were collected from questionnaires including sociodemographic variables, perception of oral and general health, and number of chronic diseases, medications and dental visits. Oral examinations included the number of absent and decayed teeth, the prosthetic status and the number of functional dental units (FUs).

RESULTS: Two hundred sixty-four participants aged 71.4±6.27 years (64.7% female) were included in the study. The mean number of absent and decayed teeth were considerably lower in high SES, and important in low SES (-p-value<0.05). The FUs and oral health perception were considerably better in high SES and worse in low SES (-p-value<0.05). A higher percentage of elderly from low SES presented a poor oral health perception due to functional problem, oral symptoms and psychosocial trouble.

CONCLUSIONS: Our results showed that the dental care system in Lebanon is not accessible for elderly with low

SES. The future appliance of the WHO Global Strategy for prevention and control of diseases might decrease the inequality in oral health for Lebanese elderly and avoid the serious health expenses.

Insomnia in elderly: correlations with somatic and psychiatric pathology

Gabrielė Kulikauskaitė¹, Rūta Jacevičiūtė¹, Aušra Deksnytė²

¹Vilnius university, Faculty of medicine, Vilnius, Lithuania

²Vilnius university hospital, clinics of Santariškės, Vilnius, Lithuania

Background and aim. Sleep onset and maintenance problems are a very common complaint among elderly individuals. The data on the etiology of sleep disruptions remains contradictory: in our survey we evaluated the connection between sleep disturbances and various medical and psychiatric conditions amid senior primary care patients.

Materials and methods. A cross-sectional study included 140 patients. The Pittsburgh Sleep Quality Index and Hospital Anxiety and Depression Scale were used to evaluate patients psychiatric symptoms and Charlson Comorbidity Index (CCI) was calculated for estimating the burden of somatic pathologies. Statistical Packet for Social Sciences 20.0 and Microsoft Office Excel 2007 were used for statistic analysis with the significance level of 0.05 assumed.

Results. Of 140 participants 53 (37.86%) were man, 87 (62.14%) women. Mean age was 66.08+/-4.677 years. 42.14% from the patient sample were suffering from sleeping disorders, 57.86% were not. Clinically significant depression symptoms occurred in 10.8% (27 patients) and 88.9% of them suffered from sleep disturbances. Among 113 patients who didn't have clinically significant depression symptoms only 30.7% had sleeping disorders. The correlation between sleep disorders and depression was statistically significant, $P < 0.05$. Symptoms of anxiety occurred in 30 patients and 93.33% of these patients also had sleeping disturbances. Only 28.8% of the patients who did not have clinically significant anxiety symptoms suffered from sleeping disorders. The correlation between sleeping disorders and anxiety was statistically significant, $P < 0.05$. Mean CCI of the sample was 0.935+/- 1.13. In those patients who did not have sleeping disorders the mean CCI was 0.6+/-0.91, in those who had it was 1.39+/-1.25. This difference was statistically significant, $P < 0.05$.

Conclusions. Sleep disorders have strong correlation with depression, anxiety and somatic comorbidity, but to find out the causality of sleeping disorders and comorbid conditions prospective research with a bigger sample is needed.

P-0489**Observational study on the appropriateness of prescribing drugs in pain management osteoarthritic with comorbidities (diabetes, Hypertension)**

Giovanni Colucci¹, Floriana Dimambro¹, Enza Colucci¹, Fabrizio Pastore¹, Silvana Francesca Parrella¹, Pasquale Iacovazzo¹, Martino Solito¹, Fabio Robusto², Vitantonio Colucci³

¹General Practitioners Asl Ta 5 Martina Franca, Taranto, Italy.

²Mario Negri Sud-Santa Maria Imbaro's institute, Chieti, Italy.

³Engineer Martina Franca, Taranto, Italy.

Osteoarthritis (OA) is cause of disability in elderly. Total costs (Italy) are estimated pro-capite 455 € (therapy, diagnostics, care gastropathy). OBJECTIVES: FANS's prescription is correlated to underlying disease and comorbidities; general practitioners (GPs) considers risk factors (age, sex, comorbidities); the most prescribed drug respects guidelines; are prescribed multiple classes of pain medications; critical/ managerial shortcomings. 8 GPs worked with a total of 12,000 patients (pz); extrapolated from data base 185 pz (M: 79, F: 115) with OA/comorbidities. Pain therapy: paracetamol / codeina (PC); FANS; opioids(O). Inclusion criteria: age ≥45; sex (M, F); diagnosis (ICD-9-CM); OA; hypertension (IA); diabetes (DM); drugs (ATC). Multivariate analyzes are adjusted for demographic and clinical factors. 185 pz: 37.8% male, 62.2% female; average age: 71; range: 45-93 years (aa). DM 22.7%, 87.6% IA. Therapy: P + C 21.6%, FANS: COX1 94.6%, COX2 27%, or 23.2%. Age groups divided in: <65 years, 65-74, 75-84 and ≥85. Years 65-75 was the most represented with: 9 DM, 46 IA and 11 DM + IA. For age range we evaluated: FANS, FANS + P / C, O. Between 65-75: FANS 45.4%, FANS + P / O 47%, OR 7.6%. We evaluated prescription drug in presence of comorbidities. DM: 47.8% FANS, FANS + P/O 47.8%, OR 4:35. IA: FANS 58%, FANS + P/O 35.7% or 6.3%. DM + IA: FANS 47.4%, FANS + P/O 52.6, OR 0%. With multivariate logistic regression (endpoints: use alternative of FANS) age > 65 (OR: 2.411, CI: 1189-4892, p: 0.01), sex is M (OR: 0.501, CI: 0266-0941, p: 0:03) are factors that induce GPs to prescribe alternative therapies. In literature there are few clinical trials for careful treatment in OA with comorbidities. Recommend greater training of GPs in management of chronic pain with attention to FANS (adverse effects) and O and cardiovascular risk factors.

P-0490**Frequency of polypharmacy among elderly home care patients**

Münevver Tulunay, Nisa Solmaz, Feyza Çelik, Doğukan Doğruel, Mustafa Arslan Bircan, Cenk Aypak, Hülya Yıkılkan, Derya İren Akbıyık, Süleyman Görpelioğlu

Department of Family Medicine, Diskapi Yildirim Beyazit Training and Resaerch Hospital

AIM: Polypharmacy is widely seen with its negative clinical consequences(1),such as drug-drug interactions,adverse effects,patient nonadherence,increasing of comorbidities,hospitalization and mortality(2).This is a particular concern in elderly patients who have cognitive and functional deficiency.The most common definition of polypharmacy is using multiple medications (5 drugs or more)(3,4).The aim of the study is to determine the frequency of polypharmacy in elderly home care patients and find the relationships between demographic characteristics, comorbidities and functional status regarding dependency.

METHODS: Patients older than 65 years and followed by Diskapi Yildirim Beyazit Training and Research Hospital Homecare Unit, were included in this study.The data about demographic characteristics,comorbidities,medications and functional status were extracted from medical files.RESULTS: One hundred and forty two patients (71.1% female and 28.9% male) were included in this study.The mean age of the patients was 79.9±6.6 years.There were 75 fully-dependent patients(52.8%) and 67 half-dependent patients (47.2%). Average number of drugs which were utilized by the patients was 5.9 per day.Of total 95 patients (66.9%) had polypharmacy. The most frequent five drug groups were anticoagulants (54.9%), angiotensin converting enzyme inhibitors/angiotensin receptor blockers (50.7%), beta blockers (39.4%), antiaggregants (32.4%), diuretics (28.2%). There was no relationship between polypharmacy and sociodemographic characteristics, comorbidities or functional status. CONCLUSION: The frequency of polypharmacy is found to be high in elderly home care patients. Physicians should focus on polypharmacy management and try to prevent inappropriate prescriptions.

Quo Vadis Clostridium Difficile Enterocolitis? Trends over last seven years

Lucia Kukuckova¹, Katarina Dostalova³, Veronika Sucha², Stefania Moricova³, Jan Luha⁴

¹Slovak Society of General Practice, Department of Long Term Ill, Derer's Hospital, University Hospital, Bratislava, Slovakia

²Department of Long Term ill, Derer's Hospital, University Hospital, Bratislava, Slovakia, Jurgos s.r.o., Outpatient Department of Gastroenterology, Bratislava, Slovakia

³Faculty of Public Health, Slovak Medical University, Bratislava, Slovakia

⁴Department of Medical Biology, Genetics and Clinical Genetics, Faculty of Medicine, Comenius University, Bratislava, Slovakia

In recent years, diarrhea caused by *Clostridium difficile* (CD) has become a frequently discussed topic. Guidelines for diagnosis, treatment, and prevention of *Clostridium difficile* infections were published in several countries, among them Slovakia. But did it lead to any change in the everyday medical practice?

We compared the incidence of *Clostridium enterocolitis* (CE) at the Department of long term ill in the years 2008 and 2014. We tested the stool specimens for CD antigen and toxin in every patient with diarrhea.

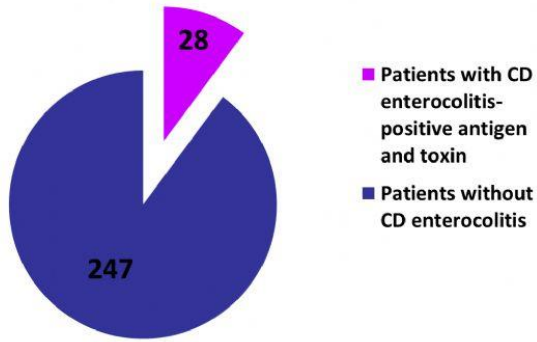

From 275 hospitalised patients in 2008 in 28 (10,2%) the toxin of CD was positive and the diagnosis CE was confirmed. Bronchopneumonia and urinary tract infections were the most frequent reasons for antibiotic therapy. Ciprofloxacin was the most used first line antibiotic in patients with afterwards determined CE. In this group combined antibiotic therapy was a risk factor for resistance to metronidazol. From 258 patients hospitalized in year 2014, 58 had diarrhea. In 22 patients (8.5%) were antigen (GDH) and toxin positive, in 24 patients (9.3%) was antigen positive and toxin negative. Ciprofloxacin was still the most used antibiotic in departments of previous hospitalisation and our department too. Only 48% patients with diarrhea used probiotics during hospitalization on previous departments, but up to 95% on our department. We analysed several other factors like presence of bowel disease, count of previous episodes of CE, use of PPI, ATLAS and CSI score.

The most used antibiotics didn't change over the years. The occurrence of CE with positivity of toxin seems to decrease from 10.2% to 8.5% (not statistically significant Fisher's exact test with $p= 0.554$), this slight decrease encourages us to stay vigilant.. Further changes in rational antibiotic prescription, use of probiotics and strict hygienic measures have to be done consistently.

Determination of the Level of Knowledge of Stroke among Patients Aged 60 Years and Older

Hüseyin Üçer¹, Hamit Sırrı Keten², Celal Kuş¹, Muzaffer Yiğit Kuran⁴, Soner Ölmez³, Mustafa Çelik¹

¹Department of Family Medicine, Medical Faculty, Kahramanmaraş Sutcu Imam University, Kahramanmaraş, Turkey

²Department of Family Medicine, Kurtul Family Health Center, Kahramanmaraş, Turkey

³Department of Family Medicine, Samsat Family Health Center, Adıyaman, Turkey

⁴Intern Doctor, Medical Faculty, Kahramanmaraş Sutcu Imam University, Kahramanmaraş, Turkey

BACKGROUND: The aim of the present study is to determine the level of knowledge of stroke among subjects aged 60 years and older.

METHOD: The present study included 172 subjects aged 60 years or older, who were admitted to the outpatient clinics at Kahramanmaraş Sütçü İmam University Faculty of Medicine for any reason between March 1, 2015 and June 13, 2015. A questionnaire including questions about sociodemographic features and assessing the level of knowledge of stroke was administered using the face-to-face interview technique. The questionnaire included 11 questions assessing the level of knowledge about the risk factors for stroke and ten questions that assessed the level of knowledge on the symptoms of stroke.

RESULTS: The mean age of the participants was 68.05 ± 7.04 years (min=60, max=88). Of the participants, 97 were females (56.4%) and 75 were males (43.6%). Of the participants, 83 (48.3%) reported that they previously heard of the terms "stroke" and 89 (51.7%) reported that they had not previously heard of this term. The mean stroke risk factors knowledge score of the participants was 7.18 ± 3.21 and the mean stroke symptoms knowledge score was 7.12 ± 2.81 . The mean stroke risk factors knowledge score was 7.09 ± 3.18 in females and 7.26 ± 3.26 in males. The mean stroke symptoms knowledge score was 7.42 ± 2.76 in females and 6.88 ± 2.84 in males. Males and females had similar achievements in stroke risk factor knowledge ($p=0.737$) and stroke symptoms ($p=0.213$) domains.

CONCLUSION: The present study showed a considerable lack of knowledge among individuals aged 60 years and older. The provision of education about stroke is very important from the perspective of health policies in this particular population, already at an advanced age, as an important risk factor for stroke.

Vitamin B12 of the elderly, a hardly visible deficit

Juliana Pais¹, Maria Miguel Sá²

¹USF Cuidar, ACeS Entre Douro e Vouga, Santa Maria da Feira, Portugal

²USF Famílias, ACeS Entre Douro e Vouga, Santa Maria da Feira, Portugal

Background & aim

The phenomenon of the increasing ageing has imposed the necessity to better understand the physiology of a body in progressive modification. In addition to the normal physiological modifications, emerge pathologies which require a specific treatment, whose interactions might condition the absorption of certain nutrients. Pharmaco-nutrient interactions can origin vitamin deficits, like of vitamin B12, after the extended taking of proton pump inhibitors (PPIs).²

The objective was to raise the awareness to the importance of the early recognition of this problem at the PHC and ease its approach and orientation.

METHOD

Article research on the evidence-based medicine databases without date limitations using the MeSH terms.

RESULTS

The vitamin B12 deficit prevails at the elderly, vegetarians and individuals with protein deficit or gastrointestinal absorption problems. Various studies report the existence of this deficit on people subject to an extended treatment with PPIs. This consequence might be more evident on older people due the existence of diverse comorbidities and the possibility of an increased pharmaco-nutrient interaction. Most of the analyzed studies affirm that there is a relation between the use of PPIs and the vitamin B12 deficit, being this process related to the treatment's duration.

CONCLUSION

Although, numerous studies try to determine the vitamin necessities at the elderly, that correlation is difficult to establish due to the many variables and different methodologies, which condition the generalization of the results.

In terms of the pharmacodynamics this relation can be foreseen, however more studies must be performed to clarify the exact mechanism of this issue.

A Comparison of the Knowledge and Awareness of Alzheimer's Dementia in the Arabic Population

Zabeena Merchant, Autumn Savage, Lesca Hadley, Richard Young

Department of Family Medicine, John Peter Smith Health Network, Fort Worth, USA

Background & AIM: People from non-Western cultures have a variety of attitudes, beliefs, and experiences with Alzheimer's dementia. The aim of this study is to determine the level of understanding of Alzheimer's dementia in Arabic-speaking patients at the international health clinic at John Peter Smith Health Network in Fort Worth TX.

METHOD: The Alzheimer's Disease Knowledge Scale will be administered by live or phone interpreters at clinic visits or over the phone. Inclusion criteria: Adult Arabic-speaking patients who have moved to the United States within the past five years. Exclusion criteria: patients ages less than eighteen and those who do not speak Arabic. Subjects will be asked about their understanding of the pathophysiology, natural history, and treatment efficacy for Alzheimer's. They will be asked about their personal experiences caring for Alzheimer's patients and their exposure to these patients in their home countries. Sub-analyses will include comparisons of subjects' responses by age, gender, and region of origin.

Results and CONCLUSIONS: Will be ready in time for the conference.

Comparison of the Quality of Life of the Elderly Living in Nursing Homes and Their Own Home and Evaluation of Relationship of This Situation With the Socio-demographic Factors

Beray Gelmez Tas¹, Dilek Toprak²

¹Beray GELMEZ TAS

²Dilek TOPRAK

AIM: In this study, it was aimed to detect the factors affecting the quality of life of elderly people living in their own homes and in nursing homes; to analyse the relationship with sociodemographic features.

MATERIAL-METHOD: 65 years and over 198 people who applied to Sisli Hamidiye Etfal Hospital Family Medicine outpatient clinics with any complaint between February-October 2014 and 202 people who live in nursing home were included the study. A questionnaire including the sociodemographic features and the Turkish short-form of the quality of life questionnaire version(WHOQOL-BREF TR) developed by WHO was performed.

RESULTS: Our study was carried out for a total of 400 patients of which 188(47%) were male and 212(53%) were female. 198 of them were living in a nursing home (first group), 202 people were living in their own home(second group). The average age of second group were 73,3±6,7 years old, while the average age of first group were 73,2±7,3. While 111 of second group(55%), were married, only 12 people(6.1%) were married in first group; 20(9,9%) of second group and 82(41,4%) of first group were uneducated. Most of the second group (n=174;86,2%) and only 4(2%) of first group got 1500 TL and over income. Mental, social, physical and environmental area scores were significantly higher in second group, than first group(p=0.000). Physical(p=0.000) and psychological area(p=0.000) scores were significantly lower in patients with chronic diseases than those without chronic diseases, in first group.

CONCLUSION: Older age, marital status, level of education, higher income and having children in individuals living in their own homes were found to affect the quality of life; sex and chronic disease affect the quality of life in elderly living in nursing homes. By informing the individuals, families and staff working in elderly care centers, the physical, social and psychological health of the elderly people may improve.

Primary and Secondary Prevention of Venous thromboembolism in seniors – Matter of Polymorbidity

Katarina Dostalova¹, Lucia Kukuckova², Stefania Moricova¹, Jan Luha³

¹Faculty of Public Health, Slovak Medical University, Bratislava, Slovakia

²Slovak Society of General Practice, Department of Long Term Ill, University Hospital, Bratislava, Slovakia

³Department of Medical Biology, Genetics and Clinical Genetics, Faculty of Medicine, Comenius University, Bratislava, Slovakia

Background.

Venous thromboembolism (VTE) is a disease of aging, with a low rate of about 1 per 10,000 annually before the fourth decade and 5–6 per 1000 annually by age of 80.

Methods.

219 patients with VTE were followed in last 6 years by the Outpatient Department of Angiology. VTE was diagnosed by colour duplex ultrasound and CT pulmoangiography.

Results.

100 (45.7%) of them were men and 119 women (54.3%), from 21 to 90 years. 20,55% of patients were 21-45 years old. 40,18% of patients were 66-90 years old. 21.6% of seniors and 13.3% of young adults suffered from PE, difference is not statistically significant (Fisher's exact test with p=0.476). We identified recurrence of VTE in 52.3% of seniors and 28.9% of young adults (p=0.018). 42.2% of young adults and 28.4% of seniors had more important thrombophilia mutations (p=0.336). 11.4% of seniors and 22.2% of young adults reported VTE in relatives (p=0.113). 34.1% seniors had malignant disease but only 4.4% of young adults (p<0.000). 17.0% of

seniors and 24.4% of young adults suffered from VTE in the context with trauma ($p=0.589$). 11.4% of seniors and 8.9% of young adults developed a perioperative VTE ($p=0.575$). 31.1% of young adults and 4.5% of seniors underwent VTE regarding to use of hormones ($p<0.000$). 4.4% of young adults and 4.5% of seniors developed VTE regarding to travelling ($p=0.426$).

Conclusions.

We have confirmed that the presence of secondary risk factors in the elderly is more pronounced than in young adults. Lower education, lower availability of modern communication technologies seem to be a disadvantage for seniors, therefore they appear to be the target group for personalized forms of education in the community.

The Phenomenon of polypharmacy among people of third and fourth age in a rural area of Crete

Theodoros Vasilopoulos¹, Georgia Arseni², Ioannis Patramanis², Vasileios Petsas², Athina Kouraki², Evangelia Souliotaki²

¹Health center of Ag.Barbara, Herakleio,Crete, Greece

²Venizeleio Gen. Hospital, Herakleio,Crete,Greece

BACKGROUND-AIM: The recording and qualitative/quantitative assessment of chronic medication among people of 3rd and 4th age in a rural setting.

METHOD: The population of the study consisted of 86 subjects ≥65 years, who attended a designated general medical office, over a period of six months, for regular prescription and who were hospitalized in a pathology clinic at least once during the year 2014.

RESULTS: 32 were men. The ages were 65-93 years old (40 persons of 3rd and 46 of 4th age). Only two subjects (2.2%) were not receiving any medication. The number of medicines per patient was up to 12, with a mean of 4.6 (4.2 and 4.8 for the third and fourth age respectively). The number of daily doses amounted to 16 (mean 5.4, 5.2 and 5.8 for the third and fourth age respectively). Individuals with higher education received lower average number of medicines (3,4 vs 4,8) and a smaller number of daily doses (3,6 vs 5,5). In all cases, the medications were prescribed by a doctor. 22 (25,5%) patients, receiving the maximum number of medicines, were not attending a personal family physician, minimizing hence the possibility their doctor to reduce their number of tablets.

The most common drugs were cardiological/antihypertensives (79.1% of patients), anticoagulants / antiplatelets (49.6%), antiulceratives 41.9%- although in most cases had no indication, and psycholeptic ie. antipsychotics / anxiolytics / hypnotics / sedatives / antidepressants / nootropic / dementia (41.7% of patients, with 1-3 compositions per patient). Among medication of the latter category, 7% granted for radiculopathies.

CONCLUSIONS: Despite the changes in the health system, the polypharmacy currently seems to be a constant phenomenon in the third and fourth age.

These results highlight the need for radical changes in the national health system and the importance of each patient to have easy access to his personal general/family physician.

P-0498**Comprehensive Geriatric Assessment of Elderly Adults in Eastern Anatolia Region of Turkey**

Hülya Çakmur

Department of Family Medicine, Kafkas University, Kars, Turkey

Background and Aim The average age of residents in rural areas of Turkey is gradually increasing. The purpose of this study is to summarise the comprehensive geriatric assessment of elderly adults living in a rural area of Turkey characterised by a relatively low level of socioeconomic development.

Method This study was designed as a prospective, cross-sectional study, conducted in a rural area of Kars Province. A total of 168 elderly adults (≥ 65 years old) were included in the study. The comprehensive geriatric assessment comprise the evaluation of general health status, cognitive function, emotional status, social support, and the caregiver burden. Cognitive function was assessed using the Standardised Mini Mental Scale. The emotional status of the participants was assessed only for depression using the Geriatric Depression Scale-Short Form.

Results The study group ranged in age from 65-96 years (mean 72.70 ± 7.73 years), and 53.6% were female, 84.3% had not completed elementary school, and 43.29% had a monthly income of ≤ 500 Turkish Liras. Eighty-one per cent of the participants were physically healthy, as they showed no co-morbidities or polypharmacy. The most frequently observed chronic disease was hypertension (45.2%). The rate of heart disease was 17.3%; diabetes mellitus (type II), 13.1%; chronic obstructive pulmonary disease, 11.6%; gastric diseases, 16.3%; benign prostatic hypertrophy, 16.7%; arthritis, 48.3%; generalised pain, 58.3%; thyroid function disorder, 4.2%; and urinary incontinence, 51.2%. Dental-oral problems were found in 57.1% of participants. The audio impairment rate was 10.7%; the visual impairment rate was 8.3%; and the smoking rate was 11.9%. The percentage of caregiver burden was 7.3%. The impaired cognitive status rate was 6.8%, depression rate was 10.9%. The rate of perceived social support and social well-being was 95.2%.

Conclusions It is believed that this study will contribute considerably to understanding the health status and needs of elderly adults living in this region.

P-0499**Robots and aging – the road ahead?**

Ana Nunes Barata

USF Amora Saudavel, Seixal, Portugal

Background

World's population is growing older and, consequently, the need for long term care is rising as many elderly lose the ability to live independently and look after themselves. In the last years, technology has been evolving fast, reaching new grounds day by day, focusing on products that want to answer to the needs of the elderly population.

The development of robotics, namely of the social robots, follows up on this technological boom. They provide solutions to improve patient's quality of life and the caretaker's task when caring for a patient with long term supportive care needs.

The presentation will consist in a brief presentation of social robots that are being developed, followed by the presentation of some observed results, namely focusing on the social robot for elderly with dementia, PARO®.

Methods

Review of the literature published in PubMed, from 2010 to 2015 on the keywords "Robot assisted therapy", "Human-Robot interactions" and "PARO robot".

Results

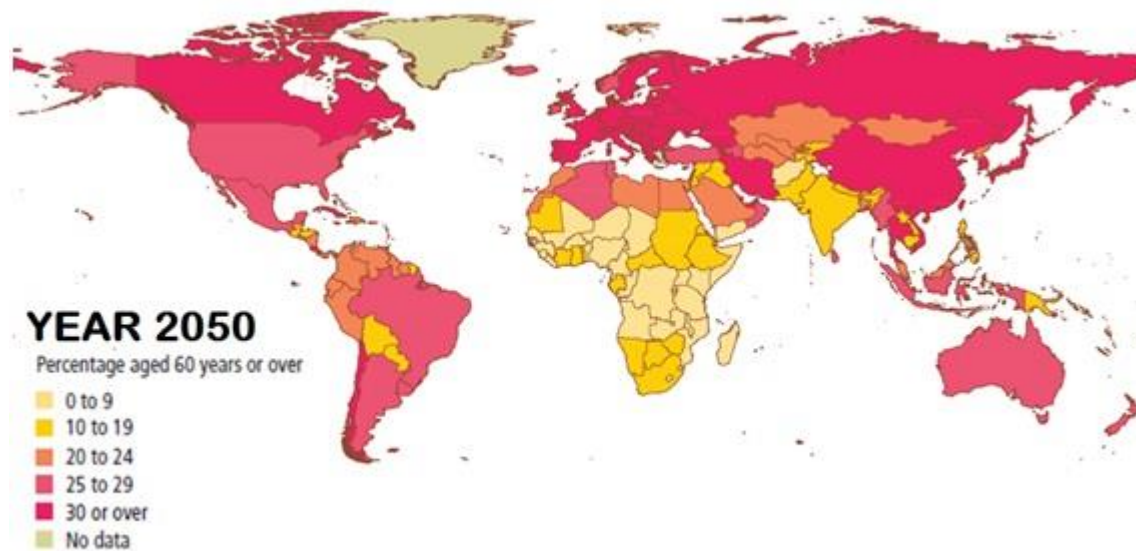

Social robots have shown to have improvements in the quality of life of elderly patients. The social robot PARO®, as it is inspired in animal assisted therapy, has shown results in reducing the level of aggressiveness and agitation, also promoting more social behavior in elderly people suffering from dementia.

Conclusions

Robot assisted therapy may be a possibility to improve elderly people's quality of life and also reduce the need for psychotropic drugs in this population. By introducing and making participants aware to the topic of “social robotics”, participants are invited to reflect on the possibilities on how to apply robots both in healthcare settings and as social interaction facilitators.

The model of care oasis: A new approach for GPs to improve care for Persons with advanced dementia

Jean Claude Leners

LTCF ALA Oasis, Erpeldange, Luxembourg

Background and AIM: Since some 6 years now we have organized two care oasis for People with advanced dementia. In order to implement definitively this model of care, an external evaluation was realized. The aim of the care oasis is to improve communication, diminish anxiety, guarantee comfort. Both care oasis are imbedded in two larger nursing homes and five GP are working in these institutions and are also part of the communication facilitators during their presences once or twice a week.

METHOD: The care approach in the oasis is well related to T Kitwood’s work on patient-centered care (in details during presentation) and the model chosen to evaluate the positive interactions between carers and patients is based on Wessel’s model on human ontogenetic.(details during presentation) The interaction between the Person with dementia and the caregiver, including the physicians, was evaluated during 14 days and communication abilities were split into several aspects.

RESULTS: The main outcome from the Patient’s point of view was: giving (to act at same eye level for both) = 71%; apathy = 5,1% and submission = 17,1%. The interaction giving was subdivided further in openness to act = 36,7% and showing personal concern in 23,7%. From the caregiver’s side, including GPs, the three major interactions were: guidance (30%), recognition or valuating the Patient (18) and negotiation (15). (All results will be displayed). Furthermore the activities in direct contact with the Patient were in the care oasis 68% of total activity, compared to 55% in a regular ward. Finally the burn-out evaluation for the caregivers showed lower values in the care oasis team (2,5) compared to regular ward team (2,9) for the emotional exhaustion scale.

CONCLUSION: The model of care oasis is an alternative for good medical practice in nursing homes for people with advanced dementia.

The Use of Proton-Pump Inhibitors Among Geriatric Patients Who Are Receiving Anti-platelet Therapy: Is it enough?

Feyza Çelik, Nisa Solmaz, Münevver Tulunay, Mustafa Arslan Bircan, Dođukan Dođruel, Cenk Aypak, Hülya Yıkılkan, Derya İren Akbıyık, Süleyman Görpeliođlu

Department of Family Medicine, Dıřkapi Yıldırım Beyazıt Training and Research Hospital, Ankara, Turkey

BACKGROUND&AIM: Although anti-platelet therapy (APT) extremely useful for the acute and chronic management of patients with cardiovascular diseases, the cardioprotective property of prolonged aspirin and clopidogrel therapy is associated with gastrointestinal complications including ulceration and bleeding.¹ Risk of these complications increases with advanced age, having peptic ulcer, use of dual anti-platelet therapy, and concomitant use of Non-Steroidal Anti-inflammatory Drugs (NSAIDs).² Proton-pump inhibitors (PPIs) are recommended to decrease the risk of gastrointestinal complications.³ The aim of this study is to determine the frequency of using PPIs among geriatric patients who receive APT.

MATERIAL&METHOD: We reviewed the medical records of 79 patients who were older than 65 years and receiving APT and followed by Diskapi Yildirim Beyazit Training and Research Hospital Homecare Unit. Patients who were receiving PPIs therapy for gastrointestinal diseases such as gastroesophageal reflux disease and gastritis were excluded.

RESULTS: Of the patients, 56 (70.9%) were women and 23 (29,1%) were men with the mean age 80.47±6.17 years. Patients were using anti-platelet agents for cerebro-vascular disease (32.9%), cardio-vascular disease (27.8%), both of them (11.4%) and other diseases (such as hypertension, diabetes mellitus) (27.8%). The ratio of patients using only aspirin was 74.7% (n=59), only clopidogrel was 15.2% (n=12) and dual APT was 10,1% (n=8). Nineteen of the patients were receiving warfarin and/or NSAIDs in addition to APT. Among the all patients receiving APT (n=79), only 26.6% (n=21) were using PPI for secondary prevention. The two most common used PPIs were lansoprazole (52.4%) and pantoprazole (23.8%).

CONCLUSION: Majority of the geriatric patients with an increased gastrointestinal risk are not treated with a proton-pump inhibitor. Identification of high-risk patients and, in such patients, incorporation of strategies to reduce their gastrointestinal risk would be clinically prudent.

Keywords: Anti-platelet therapy, Proton-pump inhibitors, Geriatric patients

Edema like a hallmark of a severe Dermatomyositis

María Fernanda Sánchez Burgos¹, Xael Pena Pérez², Enma Marianela Morales Espinoza², Carmen Barrio Ruiz¹, David Herrero Barrera²

¹Primary Care Center Camps Blancs. San Boi de Llobregat. Barcelona, Spain.

²Emergency Department and Internal Medicine. General Hospital. Parc Sanitari Sant Joan de Deu. San Boi de Llobregat, Barcelona Spain

Summary:

Dermatomyositis is a type of inflammatory myopathy that affects skeletal muscle and skin which include a generalized erythema, heliotrope rash, and/or Gottron's papules. Generalized or limb edema is an uncommon manifestation of dermatomyositis. We report one case who presented upper extremity edema.

Case description:

A 83-year-old woman, who presented left upper extremity edema, pruritus of face and hands, accompanied by hoarseness and dysphagia mixed 15 days ago. Analytical, X-ray, thorax Computerized Axial Tomography (CAT), cervical CAT, and electrocardiogram results were normal. Endoscopy of stomach suggested neoplasm gastric; biopsy was taken. Abdominal CAT showed increased uptake mural thickening and gastric lesser curvature, solid liver lesion in segment VII suggestive of M1. A week later, the patient presented weakness neck muscles. For suspected inflammatory myopathy in context of gastric neoplasm, creatine phosphokinase (CPK), immunological study, and electromyography were requested. CPK was 1008, and left deltoid muscle biopsy was required. Afterwards heliotrope rash and Gottron's papules were evident. Gastric biopsy showed mixed type invasive carcinoma. The muscle biopsy revealed an inflammatory myositis; and the electromyography showed a myogenic involvement in all of 4 limbs and bulbar muscles, consistent with inflammatory myopathy. We started corticosteroid treatment. This case was presented to the oncology committee, and due to the presence of metastases, oncospecific treatment was dismissed. The final diagnosis was Dermatomyositis with secondary gastric neoplasm. Immunosuppressive was introduced. She presented initial clinical improvement, but finally she showed progressive decline until her death.

CONCLUSIONS:

In a case of unilateral edema we have to make a differential diagnosis between vascular, systemic and infectious diseases. In our case, muscle weakness was the reason for suspecting of dermatomyositis. A literature review shows that edema is a hallmark of a severe dermatomyositis that requires aggressive treatment.

Complications of urinary catheters in elderly

Theocharis Georgios Lепенos, Maria Dimitrios Liarou, Dimitrios Lampros Mpellos, Panagiota Vasileios Prasinou Tzormpatzaki, Roza Ioannis Koliogeorgi, Vasileios Ioannis Spatharas, Spyridon Panagiotis Skoufias, Eirini Matthaïos Sveroni

Health Center Amfikleia-Lamia Hospital-Greece

Background

Elderly people are more likely to require urinary catheterization for longer periods of time due to a variety of medical problems. Our purpose is to turn General Practitioners' attention to the commonest complications of long-term catheterisation in the elderly.

Methods

The usual practice for indwelling catheters is to change them every 4-5 weeks. Between May 2013 and April 2014 we studied 52 patients (45 men and 7 women) older than 65 years of age who attended the Health Center, seeking medical attention before the planned date for the catheter change. They all had had complications related with their catheters.

On assessment, patients reported a constellation of symptoms including tiredness and lethargy, confusion, fever and rigors, being generally unwell, changes in urine ("milky", "cloudy" or bleeding), abdominal pain, dysuria and large amounts of urine leaking around the catheter.

Results

The complications related with indwelling catheters in the study population were: 34,6%(18) urinary tract infections; 42% (22) catheter blockage or obstruction, 9.6% (5) bladder spasms, 13.4% (7) urethral Injury. In patients with urinary tract infection, the catheter should be changed and a urine sample from the newly inserted catheter should be sent for MC+S.

Patients with mechanical complications (leakage, blockage (encrustations)) might do better if their catheters were changed more often.

The most commonly prescribed drugs to relax the bladder and prevent spasms were anticholinergics.

Urethral injury is a common, especially if the catheter is inserted forcefully.

Conclusions

Catheter complications usually require replacement of the catheter. Long-term catheter users need to be well trained in the management of their catheters, as their quality of life may be seriously affected by the above mentioned complications. The use of urinary catheters should be avoided whenever possible.

Assessment of nutritional status in the elderly and its relationship to social and health factors

Ruth Muñoz Maya¹, Carmen María Jiménez Herrera², Diana Dominguez Jiménez³

¹CS Don Paulino García Donas, Alcalá de Guadaíra. AGS Sevilla-Sur, Andalussia, Spain

²CS Nuestra Señora de la Oliva, Alcalá de Guadaíra. AGS Sevilla-Sur, Andalussia, Spain

³CS Estepa, Estepa. AGS Osuna, Andalussia, Spain

Background: Aging is accompanied by changes in body composition, physiological functions and activity patterns, which can modify the nutritional needs and intakes and can lead to protein-energy malnutrition. As factors involved in the nutritional status of the elderly are: physiological, socio-economic, medical, habits (alcohol, smoking), lack of health care in the issue (lack of diagnosis or iatrogenic)

Aim: To analyze the prevalence and degree of malnutrition in the elderly patients in our clinic.

Method: observational, descriptive, cross-community study.

>Population: random sample of 200 over-65-year-old patients who attend our primary care centre, placed in Seville (Spain)

>Independent variables:

- Age
- Gender
- Nutritional status, assessed by Mini Nutritional Assessment Test, physical examination and analytic parameters.

>Dependent variables (under study): socio-health factors.

- Acute Diseases
- Chronic diseases
- Drugs intake
- Recent hospital admissions
- Surgeries
- Toxic Habits
- Office Admissions

Conclusions: Nutritional assessment in the elderly can be carried out reliably from primary care services. The results of this study shall show not only a theoretical nutrition level of the elderly population, but an approach to the various risk factors that we can influence as primary care physicians, both at an individual as a community level

Results: Our research is at data collection phase, the results will be shown at the Conference. Literature tells us that nutritional status of the elderly population is a key indicator of health. In Spain 5% of apparently healthy elderly in the community may have malnutrition. Disease related malnutrition reach between 10-55% of people in areas without food shortage. Most of the studies about nutrition in older patients are sampled institutionalized elderly population and home hospitalization units. However, few studies are launched in the elderly in the community.

immunization status in the elderly:what are the attitudes of health care workers and improving precautions?

Orhan Yildiz, Saliha Serap Çiftçili

Marmara Medical School, İstanbul, Turkey

INTRODUCTION: The aims of this research are to explore attitudes of health care workers in primary health care workers towards elderly immunization and to define the barriers against it.

METHOD: There were two phases in the study. In the first phase; Health Care workers (physicians and nurses) who work in Family Health Centers and people over 65 years of age who admitted to these centers between 15.08-15.12.2014 were evaluated. Datas were collected from 583 participants by the help of three different questionnaires. In the second phase of the study, qualitative data were collected from the 26 volunteers who accepted to be in the focus group interviews. Six focus group and three in-depth interviews were conducted by two educated researchers. The interviews were audiotaped and transcribed verbatim.

In the statistical analysis of quantitative data, descriptive statistics, chi—square test and Student’s t test were used. Thematic analysis was used to encode the qualitative data.

RESULTS: Of the elderly participants; 65,3 % (n=235) thinks that vaccination is unnecessary in their age group; 57,5 % (n=207) said that they has been vaccinated at least once last year. Of the family physicians participated in the study, 66,4% (n=75) told that they knew the vaccines necessary for this age group. Of the family health care center nurses, 50,9% (n=56) says that they know the vaccines for this age group. The participants pointed out lack of integration in between different levels of health care system, lack of follow-up and records of adult immunization, problems with availability of certain vaccines in the market and workload excess as barriers against adult vaccination.

CONCLUSIONS: In conclusion, most of the elderly participants were not aware of the subject. Need for post-graduate and public education came up and public education material such as brochures or TV spots was offered as a solution.

Evaluation of patients for mild cognitive impairment/dementia and/or geriatric depression who are 60 years or older, admitting to Numune Research and Training Hospital Family Medicine Polyclinics with any kind of complaint and symptoms

Çiğdem Ünsal, Irfan Şencan, Adem Özkara

Department of Family Medicine, Ankara Numune Research and Training Hospital, Family Medicine Department

BACKGROUND: MCI (mild cognitive impairment), dementia and depression are important medical problems in elder patients. These diseases are often underdiagnosed in family health units due to several reasons caused by doctors, patients and relatives of patients. Patients who have these diseases often admit to family health units but only half of the patients can be diagnosed correctly.

AIM: In this study we aim to investigate the number of patients to be diagnosed for MCI/dementia and/or geriatric depression who are 60 years or older, admitting to Numune Research and Training Hospital Family Medicine Polyclinics with any kind of complaint and symptoms.

METHOD: For the diagnosis of MCI/dementia MoCA, for the diagnosis of depression Geriatric Depression Scale is administered. The relation of these diagnosis with sociodemographic data (age, marital status, education level, number of offspring, job/retirement status, residence, nursing status, health insurance, level of income, social activities/hobbies, praying habit) medical conditions (usage of assistive device, existence and number of chronic disease(s), smoking-drinking alcohol, sleep and pain problem, perception of age/health of himself/herself) and laboratory parameters (B12, folic acid, TSH, Hemoglobin, LDL, HDL, triglyceride) are evaluated.

CONCLUSION: The study is in process. Results will be discussed at the congress.

Keywords: dementia, geriatric depression, mild cognitive impairment, primary care, family medicine

P-0507

Primary health care for elderly people in General Practice

Sevdalina Alekova Todorova

Department Family medicine and Ophthalmology, Faculty of Medicine, Trakia University, Stara Zagora, Bulgaria

INTRODUCTION:

In European countries human population is aging rapidly and the providing of quality care in the front-line health care to elderly people is a major challenge for health care systems. The health care of elderly people is also a large part of a general practitioner's work. Co-morbidity, difficulties in communicating, the problems of poly-pharmacy and the need for additional support for the increasingly dependent patients in general practice are important issues in the care of older people.

Goals:

The aim of this study is to determine the role of family doctors in solving a number of medical and social problems in the elderly and in providing quality health care.

MATERIAL-METHODS:

The main methods, which we used in pursuance of the objective are monitoring by the family doctors of the elderly and subsequent interviews with general practitioners regarding the problems in the medical and social nature of these elderly and geriatric patients.

DISCUSSION and RESULTS:

Family doctors are key player in the process of caring for elderly and geriatric patients. On the basis of their professional competence, they participate not only in medical care for the elderly people, but also mental and social assistance of the elderly.

CONCLUSION:

With reference to the study of the basic medical and social problems in the elderly is necessary to develop a complex prevention-oriented program for medical and psychosocial geriatric care in Bulgaria with several priorities:

- Preservation of good mental and physical health of older people through prevention.
- Early detection and intervention of mental degradation, dementia
- Minimize a disability and preserving the autonomy of the elderly by supporting a network of services based on the individual needs of the patient.

P-0508

Aging and Depression: Present and Future

Romina Martínez Liñares, Sandra M^a Ayude Diaz, Noa Otero Leiro
Complejo Hospitalario de Pontevedra, Galicia, Spain.

BACKGROUND AND OBJECTIVE

82-year-old woman, independent to the basic activities of daily living, partner with married son and 2 grandchildren.

Personal history: atrial fibrillation, hypertension and Dyslipidemia. Osteoporosis. Ulcers in chronic venous insufficiency. Surgery of cholecystectomy and right wrist fracture.

Treatment: Sintrom, Ibandronic acid, Bonesil-D, Simvastatin, Enalapril, Pantoprazole, Ibuprofen, Pregabalin, Duloxetine.

METHOD

Patient with the described background, featuring multiple attendances in the last 2-3 years to hospital emergency room, emergency health center and consultations in primary care by different clinical pictures such as: morning sickness, malaise, headache, sweating, palpitations, Dyspnea morning, generalized pains. Referred for study in rheumatology, cardiology and gastroenterology services, ruling out organic pathology. Tracking by primary, according to diachronic evolution of symptoms, the patient referred sadness that's corroborated by the son, associated with progressive loss of physical faculties associated with aging and without a trigger clear.

Before a so Motley picture with non-specific clinical and affectation of mood, as you suspect disorders on the emotional scale is set: Adaptive mood disorder depressive vs depression with somatic symptoms, subsyndromic, vascular...

It's derived the unit of psychogeriatrics, where treatment is adjusted (Duloxetine, alprazolam and Trazodone) and begins psychotherapy.

Complementary tests: ECG, blood-count, coagulation, Biochemistry and brain-CT all normal.

RESULTS

Narrow tracks from primary and Psychogeriatrics, trying to make comprehensive care, both the patient and their environment and a management multidisciplinary face to the future, achieving thus a favorable evolution of the patient.

CONCLUSIONS

The relevance of this case is the importance of the psychogeriatrics. In Spain 17% of the population is older than 65 years, and 25% of these, is older than 80. The progressive aging of the population and characteristics of mental disorders in old age, justify the need for specific training on this topic, as well as research in Gerontology and Geriatrics and the development specialized programs in all the levels of care mental health.

Keywords: Aging, Depression, psychogeriatrics

²Primary Healthcare Research Support Unit Metropolitana Nord. Institute of Primary Care Research (IDIAP) Jordi Gol. Barcelona, Spain

³Residence for the Elderly Catalan Institute of Assistance and Social Services

Background and AIM: 75% of all falls come to happen in elderly people over 65 years. Having suffered a fall is itself a risk for a new one. The aim of the present study is to determine the balance and fear of falling of people >70 years-old in order to plan further community interventions.

METHOD: Cross-sectional study. 951 patients older than 70 years-old from 5 different Surgeries and able to walk (with or without any device) have been included. Exclusion criteria: Pfeiffer \geq 5, patients unable to get out of the house, palliative patients and those receiving walking rehabilitation in the last year.

The recruitment has been made by mean the Surgery phone list of people selected according to age.

RESULTS: 59.4% women, mean age 76 years, mean BMI 28.3, crutches for walking 12.6%, mean functional capacity (Lawton and Brody's test) 4.7 in men and 7.6 in women, mean fear to fall (shortened FES-I) 9,2 (score from 7 to 28 points where low scores mean lower fear to fall), balance assessed by mean Wii from Nintendo 61.5% (score from 0 to 100 points where higher scores mean better balance), balance and gait assessment by mean Tinetti's test (balance 14.6 out of 16, gait 11.2 out of 12, total 25.8 out of 28), balance assessment by mean unipodal test (patient is capable 70.5%). Fall rate during a 12-months period prior to inclusion: 32.8%.

CONCLUSIONS: Although an acceptable balance and gait score, our cohort show up an important fall rate 12 months prior to inclusion. Taking into account that almost the entire elderly population is visited in a Primary Care Surgery we suggest that preventive strategies in order to lower the number of falls and their physical, psychological and economic consequences should be encouraged.

Background & Aim

According to WHO in 2010, an estimated 524 million people were aged 65 or older (8% of world's population). By 2050, it is expected that this number will ascend to about three times more (about 1.5 billion), representing 16% of the world's population. The traditional medical evaluation is known to be reasonably effective in most individuals. However, in elderly patients some prevalent problems tend to go unnoticed. This paper aims to signal the specificity of geriatric clinical assessment, crucial for a better therapeutic management of various problems, as well as prevention of disease and disability in this age group.

Method

Classical literature review in: textbooks/guidance manuals, medical society guidelines, systematic reviews and articles published in scientific databases. The authors conducted a search with the MeSH term "geriatric assessment" in UpToDate databases, NHS evidence, Cochrane and PubMed. The articles were selected for their adequacy and scientific relevance.

Results

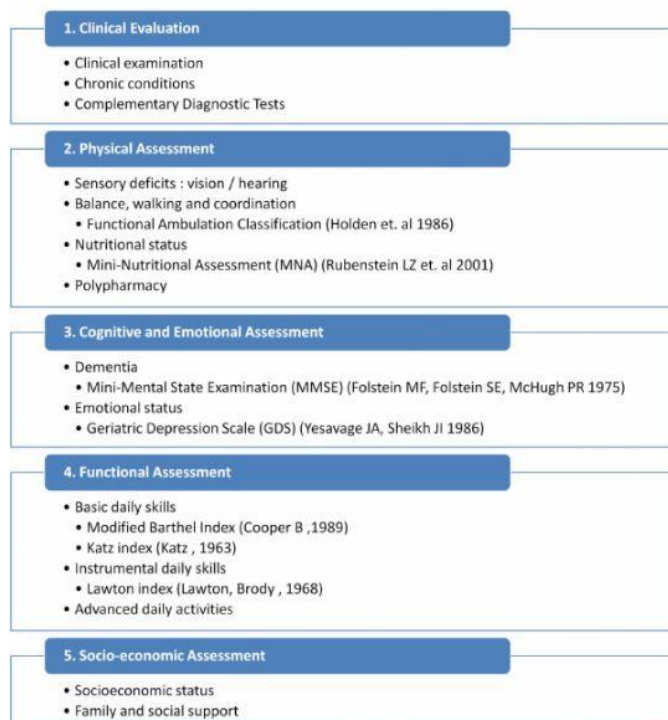

The geriatric patient presents biological and psychosocial specificities that should be considered. A tendency for omission of some symptoms and limitations; the complex pattern and the atypical presentation of the disease spectrum (less consistency between disease and clinical manifestations); the highest morbidity and mortality and more rapid progression of some diseases are some of the most important characteristics to attend.

Conclusions

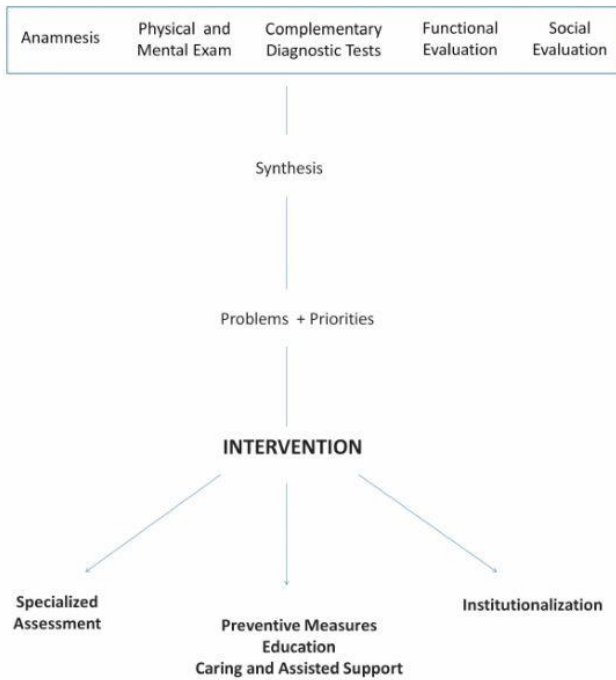

The geriatric assessment differs from a standard medical evaluation in many aspects: the frequent need of more time for the interview and clinical examination; the presence of complex problems and multiple co-morbidities in most individuals; the particular emphasis given to symptomatic relief, functional status and quality of life. This assessment should be made, whenever possible, by a multidisciplinary team, allowing a higher quality and comprehensiveness in patient care.

Vaccination of all adults of 60 or more years against Herpes Zoster. What is the evidence?

Álvaro Pereira¹, Maria Inês Capitão¹, Sandra Pereira¹, Sofia Pinheiro Torres²

¹usf bom porto, aces porto ocidental, porto, portugal

²usf aquae flaviae, aces alto tamega e barroso, chaves, portugal

BACKGROUND & AIM: Shingles is a painful skin rash caused by herpes zoster virus, the same virus that causes smallpox. Despite the host can recover from smallpox, the virus is never eradicated. He stays numbed in nervous cells and can return as shingles. Approximately 1 in 3 people will have herpes zoster infection through lifetime. After 50 years old, risk and severity increases because of lower immunity caused by age. In Portugal there is a vaccine approved since 2006 against herpes zoster for adults with 60 or more years. This vaccine is approved by the FDA for adults over 50 years old. The aim of this work is to review the available evidence of the benefits in vaccine routinely all 60 or more years old adults.

METHOD: Search of articles in databases of National Guideline Clearinghouse, NHS Evidence, Canadian Medical Association Practice Guidelines, The Cochrane Library, DARE, Bandolier, Pubmed e TRIP Database, in portuguese, spanish and english, published between January 2010 and December 2014. Use of mesh words Herpes Zoster and Herpes Zoster Vaccine. Quality of evidence and strength of recommendation was determined based on Strength of Recommendation Taxonomy (SORT) of American Family Physician.

RESULTS: We collect 262 articles. 249 were excluded because they didn't meet the inclusion criteria. We admitted 11 articles: 10 guidelines and 1 sistematic review.

CONCLUSION: Despite being approved by FDA for adults over 50 years old, all guidelines recommend one single dose of vaccine in adults over 60 years old (SORT A). Patients with chronic medical conditions should be vaccinated, unless it is counter indicated. Vaccine showed efficacy in reducing cases of shingles, as well as lowering severity of postherpetic neuralgia(SORT A).

How Much Are Geriatric Patients Dependent? Evaluation and Comparing With Serum B12 Vitamin Levels

Elif Serap Esen¹, Dilek Toprak¹, Berrin Karadağ², Halenur Yiğitbaşı¹

¹Department of Family Medicine, Şişli Hamidiye Etfal Training and Research Hospital, İstanbul,Turkey

²Department of Internal Medicine, Acıbadem University, İstanbul,Turkey

AIM: The aim of this study was to investigate dependence of people over 60 years old in daily lives and to evaluate the relationship with serum vitamin B12 levels.

METHODS: Retrospectively 423 geriatric patients between 2008-2012 in Şişli Hamidiye Etfal Training and Research Hospital Geriatrics Clinics scanned and 129 were included. Lawton Instrumental Activities of Daily Living Scale (LIADLS) was used to evaluate the dependency level of the subjects in their daily lives. Serum B12 levels recorded and B12 <250pg/ml was accepted as B12 deficiency. Body mass index (BMI) 30kg/m² were considered as obese. Descriptive and frequency analysis, Chi-square and t-tests were used by using SPSS 20.0; p<0,05 was considered statistically significant.

RESULTS: Totally 129 patients were collected. 102 were female (%79.1), 27 were male (%20.9). The mean age of the patients was 73.24±7.27 (min=60, max=89). Most of them were living with their spouse (%34.9; n=45) and relatives (%34.9; n=45), and %63.6's patients were not married (%63.6; n=82). Mean BMI was 29.92±5.17 (min=17.80, max=54.1). Most of them were obese (%45.7; n=59). There were no significant relationship between LIADLS and gender, BMI and marital status (p>0.05). Older people who had low B12 levels; needed more help for daily activities (p=0.003). LIADLS results showed that as they are older they were more dependent to other people (p=0.000). Geriatrics patients living with spouse or alone were more independent in daily activities rather than patients living with relatives (p=0.031).

CONCLUSION: There is a relationship between B12 levels, age, living style and daily living activities. Geriatric patients should be supported to live independent and their B12 levels should be regulated. This would increase the quality of their lives.

Spontaneous Fracture in Nursing Home Patient: Case-Report

Oğuz Yılmaz¹, Abdurrahman Çınar¹, Nil Tekin²

¹Department of Family Medicine, Faculty of Medicine, Dokuz Eylül University, Izmir, Turkey

²Narlıdere Geriatric Care Center and Residential Home, Narlıdere, Izmir, Turkey

INTRODUCTION:

The spontaneous fractures occurred in elder patients who were more likely to be bedridden. But there are not many reports of spontaneous fractures in nursing home residents. In this study, we aimed to evaluate spontaneous fracture in long-term bedridden nursing home patient.

CASE:

Osteoporosis was diagnosed in a 77-year-old patient in nursing home for eight years. Intolerable to biphosphonate treatment, she started Strontium ranelate 2gr 1x1 and 600mg ionized ca+400 iu Vit-D3 1x1 and stopped these. She was bedridden for two years and using wheelchair. Having HT, Hyperlipidemia, Epilepsy, Right-Sided Hemiplegia, Dementia, she used valproic acid and PPI for a long time and had a sedentary, unexercising life. Family physician examined the patient without any reported falling/trauma for right leg shortness. She had thigh-shortness and pain and crepitation during movement. Not having tibia, vertebra sensitivity, fracture and open fracture, open wound, edema, hematoma and ecchymosis in other parts, but only hemiplegia in extremity, she was referred to orthopedics for femur midline fracture after splinting right-lower extremity and had operation. In DEXA, L1-L4 T-score was -3.6 and proximal femur T-score was -3.0. Not having secondary osteoporosis, she was diagnosed with senil osteoporosis. Feeding solution and D-vit drop 1x8 drop were continued.

Ageing causes rather complex, important changes in bone-tissue and metabolism. Mechanisms causing senil osteoporosis are combination of responses to the changes in bone-cellular structure and hormonal and nutritional factors. Senil osteoporosis causes trabecular and cortical-bone losses. Patient's age, femality, sedentary life, unexercising, cerebrovascular problem, insufficient sunlight, long valproic acid and PPI usage are the most important risk factors.

In osteoporotic bedridden patients, spontaneous fractures may have occurred as a result of undocumented falls. Prevention and management of spontaneous and traumatic fractures are the same. Family physicians can give a education for caregivers about spontaneous fractures in nursing homes.

Polypharmacy in the elderly patients of the health center (USF Servir Saúde)

Patrícia Amaral, Ana Guiomar, Patrícia Silva, Sérgio Marques, Vanda Estríbio

USF Servir Saúde, Corroios, Portugal

Background and AIMS:

Ageing is associated with an increased prevalence of chronic conditions which lead to polypharmacy. Biological processes of senescence originate increased susceptibility to iatrogenia. The use of anxiolytics / sedatives / hypnotics in Portugal has increased and falls in the elderly are often related to their use. The aims of this work were: to find how many patients ≥ 75 years old have ≥ 5 drugs in the chronic prescription list; to know how many of them have anxiolytics / sedatives / hypnotics and/or trimetazidine on that list.

METHOD:

This was an observational study done in 2014. The data was collected from the patient's clinical processes. The processing was made in Excel program.

RESULTS:

We included 1177 elderly patients. From these, 60.7% had ≥ 5 drugs in their chronic prescription list. On average, each of them was using 6 drugs. The anxiolytics / sedatives / hypnotics were chronically prescribed to 20.7% of the elderly. Trimetazidine was only present in 1.7% of the lists.

CONCLUSIONS:

Most seniors of our health center are polymedicated, which may indicate a need for therapeutic review. The

prescription of anxiolytic / sedative / hypnotic may lead to negative consequences. Prescription simplification is now a clear priority. We propose implementing strategies such as the more frequent review of the medication, education of the patient and caregiver and the application of the Beers' criteria and STOPP / START. This will help to differentiate drugs with low efficiency and high risk from those essential and safe for our elderly patients.

P-0515

Statins in primary prevention: what data and issues for patients aged 75 and older?

Jean Philippe Joseph¹, Mélanie Afonso¹, Fabrice Bonnet², Bernard Gay¹

¹General Practice Department, Bordeaux University, Bordeaux, France

²Saint André Hospital, Bordeaux, France

Background and AIM: High cholesterol is a risk factor for cardiovascular diseases. Statin prescription in primary prevention reduces these events from 20 to 30% and mortality from 10% in large randomized trials. The question was to know if these results persisted for the patients taking statin after 75 years old.

METHOD: Methodic review of large randomized trials and meta-analyses which included patients of age 75 and older treated with statin in primary prevention. Data base: Medline.

RESULTS: A score of randomized controlled trials studying statins versus placebo in primary prevention were published and analysed in meta-analyses. Despite the power of these studies, some limits may be raised. The inclusion criteria were usually restrictive and age 70 and older is often an exclusion criterion. Furthermore, the impact on mortality has not been demonstrated in elderly. Recent meta-analysis of observational studies including subjects between 70 and 89 years old treated with statins found that low total cholesterol was associated with a moderate decrease in cardiovascular mortality but no reduction in all-cause mortality. The cardiovascular mortality in the elderly involves multiple causes of death and the role of statins is much less clear than in the under aged. In addition, in a common context of polypharmacy, statins may be responsible for numerous side effects, drug interactions and impaired quality of life.

CONCLUSIONS: Given the lack of formal evidence of effectiveness, the benefit / risk balance of primary prevention with statins is not established in the elderly. The SITE study (Statins In The Elderly), which recently started with public french funding, will attempt to answer this question by a multicentre randomized trial. Its endpoint will be to assess the impact in real life, of the statin cessation in patients after 75 years old treated in primary prevention.

Orthostatic Hypotension in Older Adults in nursing home: prevalence and impact of a routine assessment

Gerard Nguyen¹, Domiique Le Moul¹, Yusuf Kocan², Nicodeme Ntambwe², Sok Naye Neam², Helene Quesnot², Zurbach Jacques²

¹Primary Care, Cabinet Marcel Monny Lobe, Soisy sous Montmorency, France

²Les Jardins d'Iroise, Epinay sur Seine, France

Orthostatic hypotension is a frequent cause of generalized cerebral hypoperfusion leading to dizziness, syncope and falls in older subjects at home and in institution like nursing home. Many recommendations of good practice have included the detection of orthostatic hypotension as a routine procedure. There is a gap between recommendations and routine practice and less data existed to show the prevalence in nursing home. We performed a routine determination of orthostatic in nursing home under the supervision of family physicians. Blood pressure measurements were obtained by nurses with the 76 subjects under supine position and after they had been standing for 3 minutes. The prevalence of asymptomatic orthostatic hypertension defined as 20 mmHg or greater decrease in systolic or 10 mmHg or greater decrease in diastolic blood pressure was 11.8% (9/76). Two patients had both systolic and diastolic BP decrease, 4 had only systolic BP decrease and 3 had only diastolic BP decrease. Five had a treatment by antidepressive drugs, 3 had only antihypertensive drugs and one had both treatments. Multivariate analysis was done to show some interrelation between orthostatic hypotension, decrease of daily activity, comorbidity, age and weight. Our routine assessment of orthostatic hypotension succeeded to raise an awareness on drug use: high dose of antihypertensive drugs, association of antidepressive drugs and overall association with hypnotic drugs in all patients, increasing the risk of falls. Our prevalence is in accordance with others published elsewhere in older populations and in other settings. Figures in nursing homes are lacking. Performing routinely on a basis of a monthly assessment is a best practice in nursing home to detect orthostatic hypotension allowing a re-evaluation of drug prescriptions, a fall prevention follow up and a caregivers continuous training, care follow up awareness procedure and team work.

Keywords: orthostatic hypotension, older persons, blood pressure measurements

P-0517

Detection of Apathy in Older Persons in Nursing Home: Routine use of NPI (Neuro Psychiatric Inventory) Questionnaire and impact in care framework

Gerard Nguyen¹, Charlotte Haignere², Stephanie Blanc², Catherine Maffon², Laetitia Sarteur²

¹Primary care, Cabinet Marcel Monny Lobe, Soisy sous Montmorency, France

²Residence ARPAGE Jacques Offenbach, ARPAD Epinay sur Seine, France

Apathy is increasingly recognised as a frequent behavioural problem in Older Persons with Dementia. It should be detected systematically. Overlap with depression has been widely described and might explain the large variation of prevalence related. Validated tool as NPI (Neuro Psychiatric Inventory) scale could be used routinely. We performed NPI in all of our 53 patients (mean age of 87 yo, 50 women) in nursing home. Forty one (77,35%) have Dementia. We used the recommended tool NPI assed by carers (NPI-ES), added with the Apathy Inventory scale. Apathy represented 30.19% (16/53) of all patients and 24.40% (10/41) of Dementia. Among those with Dementia and Apathy, 43.75 % (7/16) have associated depression. Only 3/7 were under antidepressant drugs and 25.00% (4/16) had anticholinesterase agents. One patient had associated Parkinson symptoms and treatment. Associated factors have been determined with multivariate analysis. Overlap between apathy and depression has been discussed with physicians.

The most important findings were that the use of scale routinely was feasible and accurate. An audit confirmed the results.

The routine use of appropriate, validated, recommended and easy to use psychometric scales as NPI in Older Persons and has allowed a change of practice by programming more non pharmacologic (cognitive stimulation approaches, balneotherapy, stimulation games), by increasing an awareness among carers to detect alert symptoms, by making some differences with depression, by re-discussing the indication of pharmacologic agents

and by proposing an re-organisation of care in Nursing Home. The non pharmacologic methods (multiple stimulation methods) have to be preferred. From the results we would recommend the use of NPI in ambulatory practice and in nursing home in a routine geriatric assessment and also in a risk management plan to decrease iatrogeny.

⁹Radiology Department; Río Hortega University Hospital. Valladolid. Spain

INTRODUCTION:

Pruritus can be defined as an unpleasant cutaneous sensation that leads to a desire to scratch. The subjective component is essential in its assessment. In some cases, a primary dermatosis is involved, or there is an underlying systemic disorder, but often no cause can be found. At least 29 % of the elderly have this symptom. Objective: To determine the incidence of pruritus in a sample of elderly dermatology outpatients consultation.

Material y METHODS:

Subjects Patients over 60 years that came into the dermatology consultation for the first time.

Type of study: transversal descriptive study

Measurements and interventions: Personal history, concomitant diseases, hygiene habits, sun exposure, use of sunscreens, presence of pruritus, dermatological diagnosis, medications were collected.

RESULTS:

306 patients: 169 women and 137 men. Average age: 72 + 7.3 (60-92 years). 54% (n = 165) of the patients recognized that have been suffering pruritus, in 29% of the patient, the itching increased at night and in 48% the itching increased with the heat. There were no significant differences related to gender and age. 75.8% did not hydrate the skin regularly. 87.3% did not perform photoprotection. 30.9% had a daily shower and 29.7% had it 2-3 days a week. The 35.56% have pruritus widely. 20% of cases are associated eczematous dermatoses found in a seborrheic dermatitis 6%, in 7% of the cases associated to urticaria and in 25% with xerosis.

CONCLUSIONS:

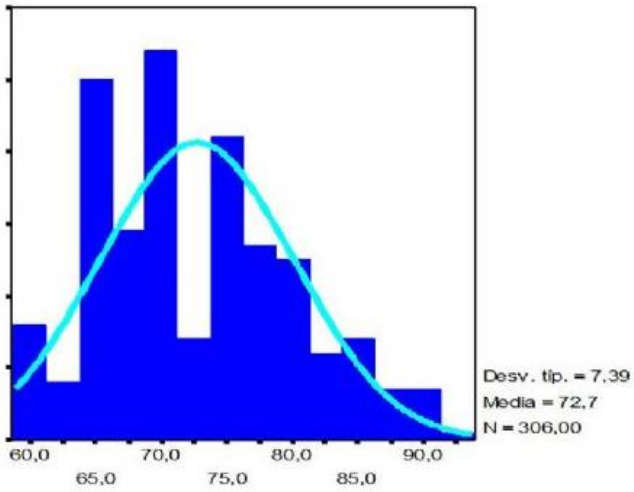

Pruritus is a frequent complaint in the population over 60 years so it is necessary to rule out a possible association with dermatological or allergic disease

Pruritus sine materia or associated with xerosis and / or dermatitis could be related to hygiene or inadequate hydration

The correct and early management of these symptoms can help to prevent the development of future complications like eczema, allergic or infectious type.

Effect of Obesity on Cognitive Functions of Individuals Aged 65 And Above

Kübra Uyar¹, Mehtap Kartal¹, Nil Tekin²

¹Dokuz Eylul University Faculty of Medicine, Family Medicine Department, Izmir, Turkey

²Narlıdere Geriatric Care Center and Residential Home, Izmir, Turkey

AIM: Cognitive functions are one of the most important factors effecting quality of life of elderly. Pharmaceuticals stop only progression of dementia so primary prevention issues become more important. Nowadays, some studies indicate that obesity can affect cognitive functions. It is aimed to study the relationship between obesity and cognitive functions among elderly aged 65 and above.

METHODS: This case-control study included 390 elderly (128 cases having mild cognitive impairment-MCI and 262 controls without cognitive impairment) living in Narlıdere Geriatric Care Center and Residential Home, Izmir, between April 2014-January 2015. Elderly weight, height and waist circumference was measured and recorded, and a questionnaire prepared by the researcher in addition to Mini Mental State Examination, Stroop Test, WMS-5 digitspan test, three words-three shapes test, geriatric depression scale, activities of daily living test and instrumental activities of daily living test were applied face to face.

RESULTS: When compared cases were found older (79.49 ± 7.06) than controls (76.25 ± 7.38) ($p < 0.001$). Cases had more impairment in simple attention ($p < 0.001$), longer total time and color word interference on stroop test ($p < 0.001$), less identification information previously learned (recall) ($p < 0.001$) than cases. Obesity history in the past was significantly higher in cases compared to controls ($p < 0.001$). Multiple logistic regression analysis was done to adjust for age, gender, time period in institution, current body mass index and waist circumference, obesity history and showed that age 85 and above had about 3.9 (95%CI: 1,5-10,3) fold ($p = 0.005$) and positive obesity history had about 9,1 (95%CI: 5.2-15.9) fold ($p < 0.001$) higher probability of MCI.

CONCLUSION: Today, as the prevalence of dementia is increasing it is important to show facilitating factors that reveals MCI and dementia for both elderly and their caregivers. Primary care physicians evaluating obese patients should take precautions not only for its cardiovascular complications but also for maintenance of cognitive functions.

Vitamin D and cognitive function in elderly – what’s the atual evidence?

Sara Magalhães¹, Ana Filipa Couto², Frederico Abreu³, Helena Ribeiro⁴, Maria João Abreu⁵, Nuno Namora⁵, Teresa Martins⁴

¹Department of USF Ponte, Guimarães, Portugal

²USF S. Miguel-o-Anjo, Famalicão, Portugal

³USF Alpendorada, Marco de Canaveses, Portugal

⁴USF Novos Rumos, Vizela, Portugal

⁵USF DuoVida, Guimarães, Portugal

BACKGROUND & AIM: Worldwide, the prevalence of vitamin D deficiency is estimated to be high in some populations of risk such as the elderly. In Portugal, the limited studies published about the vitamin D deficiency, estimates a 93% prevalence.

Despite the recommendations of American Guidelines, in Portugal there isn’t a screening program for vitamin D deficiency on risk populations.

The possible consequences of vitamin D are well established such as disturbances of calcium metabolism, autoimmune diseases, and neoplastic, infectious and cardiovascular diseases. Lately there have been some studies relating vitamin levels with cognitive activity, whose deficits could have important consequences on the quality of life of vulnerable groups.

This study aim was to review the current evidence on the relationship between levels of 25-hydroxyvitamin D and cognitive function.

METHODS: It was performed a literature search on MEDLINE databases of articles published in the last five years, using the MESH terms: "cognition", "aged" and "vitamin D", at January 2015.

RESULTS: The search resulted on 35 articles of which nine were studied further (one randomized controlled trial, five cohort studies, two cross-sectional studies and one review).

DISCUSSION /CONCLUSION: Despite the heterogeneity of the studies, the majority is on agreement that deficit levels of vitamin D are associated with cognitive impairment with a level evidence of 2 (SORT B). However, we need more randomized controlled trials verifying a causal relationship between vitamin D deficits and cognitive disability. The recommendations for screening and benefits of supplementation are not still established.

Keywords: Mesh words: cognition, aged and vitamin D.

Epidemiology of Hip Fracture in the Elderly in Castile and Leon (Spain)

Rosario Martinez Fuerte¹, Leticia Sierra Martínez¹, Iker Sierra Martínez², Natalia Sanz González³

¹Valladolid Este Primary Assistance Gerency, Sacyl Castile and Leon, Valladolid, Spain

²Traumatology Department, Hospital of Medina del Campo (Valladolid), Spain

³Parquesol Senior Center, JCyL Social Serices Gerency, Valladolid, Spain

AIMS:

Using the records of the Medical Record Informatics (MRI) to determine the prevalence of Fracture of the Hip fracture (HF) in patients with osteoporosis (OP) to promote preventive activities from Primary Care physician and. Specialist in Orthopaedic Surgery and Traumatology

DESIGN:.

Most HF occur in elderly patients with OP, consuming significant resources, health, social and economic in the process of diagnosis and treatment. The authors conducted a descriptive cross-sectional study of patients with HF in patients with OP record in the MRI of the urban health center in Castile and Leon (Spain).

METHOD: From the list of selected patients with MRI 753 with a diagnosis of OP, we studied the OP prevalence and Epidemiology HF. We analyzed the causes of the fracture. The data is collected on an Excel spreadsheet and analyzed using SPSS 9.0 for Windows.

RESULTS:

-Patients with OP in our health center corresponds to 20% of the population over 50 years.

-Of the 753 patients with OP: 687 women and 66 men. Ratio of woman OP/men OP:10/1.

-Of the 687 women with MRI in the diagnosis of OP:35 cases of HF. Women OP-HF:Prevalence:5,09%

-Of the 66 men with MRI in the diagnosis of OP: 2 case of HF. Men OP- HF prevalence: 3 %

-Falls at home was the cause in 84% of cases. For defects of vision, collision with obstacles and falls from ladders.

CONCLUSIONS:

20% of the population over 50 years of our health center, has recorded in his MRI OP the clinical process, with Ratio of womanOP /menOP:10/1

and OP-FIR Prevalence of woman / men 2 /1, which justifying the implementation of a Health Improvement Plan, including Education Program for Health aimed at groups and the development of preventive activities in Primary Care consultation and Specialist in Orthopaedic Surgery and Traumatology

Keywords: Elderly; osteoporosis; Hip fracture.

The Importance of Cognitive Impairment Screening for elderly People in Community

Nita Arisanti, Elsa Pudji Setiawati

Department of Public Health, Faculty of Medicine, Universitas Padjadjaran

Background

During recent decades, the world population entered a process of aging. With the elderly population in lower and middle-income countries predicted to increase from 60% in 2001 to 71% by 2040, many problems rise in the elderly population. One of the health problems is cognitive impairment. Primary care clinicians may fail to recognize cognitive impairment during clinic visits using routine history and physical examination. About 29 to 76 percent of patients with cognitive impairment are not diagnosed by primary care physicians. The objective of this study was to identify the number of cognitive impairment in elderly people.

Method

This was cross sectional study involving 272 elderly people in Cianjur Indonesia. The Short Portable Mental Status Questionnaire (SPMQ) was used to collect data and analyzed using Contingency Coefficient.

Results

From a sample of 272 respondents 57% were female with the average age was

67.72 years (SD=9.76). Most of respondent (44.7 %) was categorized as moderate cognitive impairment, 43.6% as mild cognitive impairment and 10% as severe cognitive impairment. There were relationship between age and cognitive impairment ($p<0.05$). The study showed that cognitive impairment was associated with increasing age. As the number of elderly in community is increasing, there should be a program to earlier detect the incidence of cognitive impairment in primary health care and community.

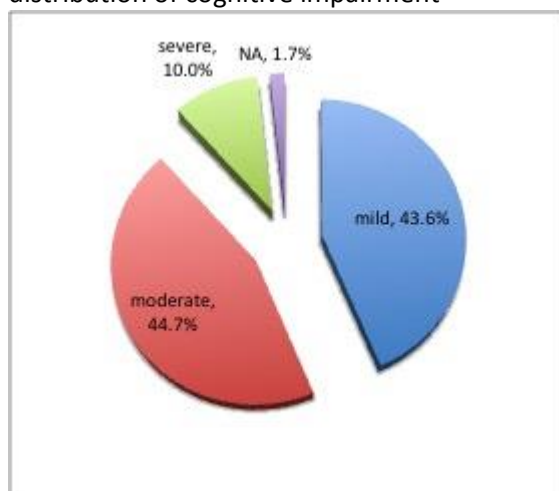

Conclusion

The study shown there was relationship between age and cognitive impairment.

Therefore, screening tests for elderly people may help identify patients with cognitive impairment who are otherwise missed.

Care of the Dying Patient

Çiğdem Gereklioğlu¹, Süheyl Asma¹, Kenan Topal², Aslı Korur¹

¹Baskent University Medical Faculty, Department of Family Medicine, Ankara/Turkey

²Adana Numune Training and Research Hospital, Department of Family Medicine, Adana/Turkey

BACKGROUND: Some diseases continue to be fatal despite the advancements in medicine. Fatal diseases are challenging for the patient, family and health staff. The aim of the end of life care is to improve quality of life, relieve pain, enable the patient be independent as possible, die with dignity and support family members.

MATERIAL-METHOD: Hospice action provides routine home care of the patients, routine home visits, nursing services and hospitalization when required. In recent years, home care services has developed in our country although hospice care is not a routine part of terminal care. Family physicians are an important part of home care. Maintenance of care through home visits should be essential in primary care of which biopsychosocial approach is

the main principle.

RESULTS: Today, the patient is examined as a whole in patient-centered clinical method which is developed by adaptation of biopsychosocial method to clinical practice, the patient is addressed with his/her living conditions, problems, family, physical environment and psychological problems and the problems are perceived with the patient's point of view. Priorities and the roles are determined together with the patient, the conception of making the best decision leaves its place to making a decision together with the patient.

CONCLUSION: Nausea, vomiting, pain, fatigue, emotional disorders, febrile neutropenia, nutritional problems are the main problems in terminal period. The patient and the family should be involved in important decisions. Spiritual needs of the patient and the family should also be met. We want to emphasize the key role of the family physicians in terminal care.

Evaluation and management of vertebral compression fractures in Castile and Leon (Spain)

Iker Sierra Martinez¹, Leticia Sierra Martinez², Rosario Martinez Fuerte², Natalia Sanz Gonzalez³

¹Traumatology Department, Hospital of Medina de Campo (Valladolid), Spain

²Valladolid Este Primary Assistance Gerency, Valladolid

³Parquesol Senior Center, JCyL Social Serices Gerency, Valladolid, Spain

AIMS:

Using the records of the Medical Record Informatics (MRI) to determine the prevalence of Vertebral Compression Fractures (VCFs) in patients with osteoporosis (OP) to promote preventive activities from Primary Care physician and. Specialist in Orthopaedic Surgery and Traumatology

DESIGN:

Most VCFs occur in elderly patients with OP, consuming significant resources, health, social and economic in the process of diagnosis and treatment. The authors conducted a descriptive cross-sectional study of patients with HF in patients with OP record in the MRI of the urban health center in Castile and Leon (Spain).

METHOD: From the list of selected patients with MRI 152 with a diagnosis of OP, we studied the VCFs prevalence. We analyzed the Association of OP and VCFs by age. The data is collected on an Excel spreadsheet and analyzed using SPSS 9.0 for Windows.

RESULTS:

-Of the 152 patients with OP:136 women and 16 men.Ratio of womenOP/menOP:8,5/1 1.

-Of the 136 women with MRI in the diagnosis of OP:9 cases VCFs:

Women OP-VCFs-Prevalence:6,6%

-Of the 16 men with MRI in the diagnosis of OP:1case VCFs.

Men OP-VCFs-Prevalence:6,2%.

-Association of OP and VCFs by age:

.In women:

- 90-100:3OP(2.2%),1VCFs(0.7%).

-80-90:47OP(34.5%),2VCFs(1.7%).

-70-80:39OP(28.7%),2VCFs(1.7%).

-60-70:36 OP(26.5%),4VCFs(3.4%).

-50-60:11OP(8 %),2VCFs(1.7%).

-In men:

- 90-100:2OP(12.5%) y 1VCFs(6.25%).

-80-90:6OP(37.5%) y 0VCFs(0%).

-70-80:6OP(37.5%) y 0VCFs(0%).

-60-70:1OP(6.25%) y 0VCFs(0%).

-50-60:1OP (6.25 %) y 0VCFs(0%).

CONCLUSIONS:

Although the ratio of prevalence of OP woman / man is 8.5 / 1, the incidence of VCFs is very similar in men and

women around 6%. The age group with the highest prevalence of osteoporosis is found between 70 and 90 years. Evaluation of burden and related factors in care givers of home care patients

Tanyel Sema Dağdeviren, Nevgül Demir, Didem Sunay

Department of Family Medicine, Kecioren Training and Research Hospital, Ankara, Turkey

BACKGROUND: In our country care of people in need of nursing is generally given by a member of the family. In this study we aimed to assess the burden and related factors in care givers of patients registered by home care service.

METHODS: The care givers of patients registered by home care service of a training and research hospital were included in this cross-sectional study. A questionnaire was used to assess socio-demographic and clinical characteristics of patients and care givers and Zarit care giver burden inventory to assess burden.

RESULTS: A total of 80 care givers were included, 85% were women, 63.7% were between 35-64 years of age, 73.8 were married, 67.5% were housewife, monthly income was less than expense in 60%, 76.3% were living with their family, 7.5% with the patient, 63.7% were the only one who gives care, 36.3% were the daughters of the patients. Mean age of the patients was 77 years, 63.7% of the patients were women, 53.8 % were bedridden, 67.5% of them had dementia. Most difficult issue in care giving was the bath of patient. 51.2% of care givers were noted that they gave care because of family responsibilities. While 86.3% of care givers were satisfied with the care they give, 56.3% need training and consultancy about care giving. Care givers' burden (CB) according to Zarit inventory was high in 43.8%, very high in 2.5% of the participants. Of those who had high CB 74.3% were noted that they gave care because there was no one to take the care of the patient. All of the care givers who had high CB were using anti depressants and felt burnout.

CONCLUSION: CB is a complex issue that is associated with several patients' and caregivers' factors. Supportive care needs to be sought to alleviate CB.

Depression in Parkinson Disease – a review

Renata Almeida¹, Joana Silva², Ana Rita Ferreira³, Joana L. Gonçalves¹

¹USF São Julião, Portugal, Figueira da Foz, Portugal

²Hospital de Magalhães Lemos, Oporto, Portugal

³USF Santiago, Leiria, Portugal

INTRODUCTION: Parkinson Disease (PD) is the second most frequent neurodegenerative disease worldwide. Non-motor symptoms in DP are getting more recognised, like depression, since they have a significant impact in patients' quality of life.

OBJECTIVES: The authors aim to review and summarize the latest literature about depression symptoms in PD.

METHODS: Literature review up to 2015, using Pubmed and the keywords depression and Parkinson Disease.

RESULTS: Studies propose that depression occurs in approximately 35% of the patients diagnosed with PD. There are some criteria and scales that may help professionals in the diagnosis and follow-up of this disease, such as Hamilton Depression Rating Scale.

Antidepressive therapy in PD has some particulars, and there are a variety of medications that can be used like tricyclics antidepressants, serotonin reuptake inhibitors, serotonin and norepinephrine reuptake inhibitors and also dopamine agonists like rasagiline. Electroconvulsive therapy and transcranial magnetic stimulation are also options.

DISCUSSION: Depression in PD is becoming a more and more recognised entity, however there are still some questions because of the overlapped existing between this two syndromes. There are some latest developments showing that rasagiline in association with a SSRI, may bring benefit for patients, despite of this, further studies are needed in order to give this patients a better quality of life.

Three factors are predictive of unrecognized atrial fibrillation. Study in primary care on a cohort of 4592 patients

Marie Catherine Reboul¹, Jean Marc Davy², Philippe Lambert¹

¹Department of General Medicine, University of Medicine, Montpellier, France

²Department of Cardiology, University Hospital, Montpellier, France

AIM:

To isolate predictive factors of atrial fibrillation (AF) in patients over 65 years old consulting in general medicine.

METHOD:

The study called PROFIL-FA was quantitative, multi-center study conducted in 2013 in general medicine practices in France in 16 territories and 13 regions, including 603 general practitioners and 4592 patients.

The patients included were 65 years old or over, with or without a known AF, whatever the reason of consulting. Taking the radial pulse was systematic.

1) The presence of one or more symptoms from a list of four AF-like symptoms (Palpitations, Episodes of faintness-weakness, Unexplained chest pain, Shortness of breath on exertion or at rest) led to the questionnaire CHA2DS2-VASc.

2) If the presence of an irregular heartbeat or positivity at the CHA2DS2-VASc questionnaire, the patient was sent to a cardiologist.

The results were analyzed using a logistic regression model with predictive evaluation by ROC curve.

RESULTS:

Of the 4592 patients enrolled, 585 were referred to a cardiologist where 129 (3.4%) unknown AF were newly diagnosed.

The main predictive factor of AF was unknown irregular heartbeat (sensitivity 74.2%, specificity 81.9%, OR = 12.0, $p < 0.0001$). Its positive predictive value remained however low (55.6%).

The presence of palpitations ($p = 0.0023$) or episodes of faintness-weakness ($p = 0.0129$) were the two other predictive factors.

CONCLUSION:

The study isolated three predictive factors of unknown AF in over 65 year old patients in general medicine practice. The systematic search of an irregular pulse is a major predictive factor but is not sufficient. It has to be associated with the search for episodes of palpitations or fainting, especially in patients with a cardiovascular medical history. This systematization would, in a quick and simple way, improve detection of unknown AF in general medicine practice.

The Knowledge, Attitude, And Behaviors Regarding Organ Donation Among Individuals Aged Over 60

Hamit Sırrı Keten¹, Hüseyin Üçer², Derya Keten³, Oğuz Işık², Fatış Yıldırım²

¹Department of Family Medicine, Kurtul Family Health Center, Kahramanmaraş, Turkey

²Department of Family Medicine, Medical Faculty, Kahramanmaraş Sutcu Imam University, Kahramanmaraş, Turkey

³Department of Clinical Microbiology and Infectious Diseases, Necip Fazil City Hospital Kahramanmaraş, Turkey

BACKGROUND: In this study, we aimed to determine the knowledge, attitude, and behaviors of individuals aged over 60 about organ donation.

METHOD: This study was conducted in Kahramanmaraş, a province in the southern Turkey. A total of 124 individuals aged over 60, applying to polyclinics of Kahramanmaraş Sütçü Imam Üniversitesi Faculty of Medicine between 01.10.2014-31.12.2014, were enrolled in the study. A survey on sociodemographic characteristics, and the knowledge, attitude and behaviors about organ donation was performed to all participants.

RESULTS: Ninety three (75%) of the participants were male, while 31 (25%) were female. The mean age was 69.42±6.11 (min=60, max=87). Thirty patients (24.2 %) stated that they were sufficiently knowledgeable about organ donation and transplantation. Fourteen patients (11.3%) noted they knew where to apply for organ donation while 110 patients (88.7%) noted they did not. Only 1 (0.8%) patient had applied for organ donation and had an organ donor card while 123 patients (99.2%) did not. Thirty seven (29.8%) participants remarked that they desired to donate their organs. Sixty one (49.2%) patients indicated that positive fatwa of the reverend would be effective to increase organ donation, while 53 patients (42.7%) told that activities of health professionals would be helpful, and 22 patients (17.7%) stated media support would be beneficial.

CONCLUSIONS: We revealed that individuals over age of 60 lacked information

regarding organ donation. Furthermore, it was observed that the willing to donate organs or to apply for this purpose was low among participants.

Evaluation of knowledge and attitudes about the elderly in aged care staff caring for older people, in Antalya Metropolitan Municipality

Ethem Kavukcu¹, Betül Moral², [Melahat Akdeniz](#)³

¹Department of Sports Medicine, Akdeniz University, Antalya, Turkey

²Metropolitan Municipality, Antalya, Turkey

³Department of Family Medicine, Akdeniz University, Antalya, Turkey

Gradually aging of the world population created the problems. One of these problems is the question about who is going to deal with the care of handicapped or old people. Today the local authorities and public health departments are trying to solve this problem by setting up home-care units. Local authorities are running disqualified workers under the supervision of a professional medical staff. The staff who cares for elderly patients, may not have enough experience and information about aging and being aged.

Materials and Methods; In this study, the profiles of the people receiving care services from Antalya Metropolitan Municipality are extracted. These people and the ability and needs of care takers of elderly nursing staff who agreed to participate in the study was assessed with a short questionnaire about their knowledge and attitudes.

Findings; 15 of the caretakers (%53) see the elderly patients as unprotected and a burden for both their families and the community. 9 of them (%32) stated that they do not agree with the previous statement. However % 28 think that the problem in communication between the caretaker and the elderly patient is caused of the elderly patient's inability,%32 stated that they disagree with that. %68 of the caretaker (19 person) think that the elderly people have more than one health problem. The rate of the ones who think its hard to satisfy elderly people is %60. The number of people who doubts if the investment on the elderly people's condition is an investment for the future is 21 (%75).

Conclusion; People who are working as caretaker for elderly patients in Antalya, are not trained in their field and they don't have enough information and qualification in their profession. Family physicians as the elderly patient's defences should be aware that caregivers do not have sufficient knowledge

Keywords: aging, caregiver, knowledge and attitudes

Subclinical hypothyroidism - approach in Geriatrics

Mara Matos Dias

Unidade Saúde Familiar Fiães, ACES ENTRE DOURO E VOUGA I - Feira/Arouca, Aveiro, Portugal

Background & AIM:

The study of thyroid function have gained importance in providing health care for the elderly, due to its correlation with physical disability, cognitive function, cardiovascular risk and longevity. Subclinical hypothyroidism is more prevalent in female population, caucasians, iodine-deficient regions, and geriatric population. However, the diagnosis in the elderly is hampered by the absence of specific symptoms, mingling with own manifestations of a physiological aging. The acquisition of skills for right diagnosis of subclinical hypothyroidism, in the geriatric population, is required for the proper treatment plan.

METHOD:

Literature search of systematic reviews and scientific articles from the Pubmed database, Medline, using the MeSH terms: "subclinical hypothyroidism" "subclinical hypothyroidism elderly." The search was restricted to articles published between the period 2004 to 2014, in English.

Results

An initial higher TSH value with free T4 values within the reference range needs to be investigated, by repeating the measurements, after 2 to 3 months, together with anti-thyroid peroxidase antibodies. If the elevation of TSH continues with a value of less than 10 $\mu\text{U} / \text{L}$, it should maintain vigilance, repeating the analysis after 6 months. If the TSH assay is greater than or equal to 10 mU / L , treatment with levothyroxine should be considered, only if the patient presents clear signs of hypothyroidism or high cardiovascular risk. TSH values should be reassessed 2 months after initiation of therapy and the drug dosage adjusted according to the results. The target value of TSH should be in the lower half of the reference range (0.4 - 2,5 mU / L). After stabilization of TSH values, monitoring of thyroid function should occur annually.

Conclusions

The treatment of subclinical hypothyroidism remains questionable, therefore a close monitoring of thyroid function could be the best option for patients at high risk of progression to overt disease.

Management of Pressure Wound: Two Doctors-Two Smart Phones

Özden Gökdemir¹, Nazmi Yoğurtçu², Ülkü Bulut³, Mehtap Kartal¹

¹Dokuz Eylül University, Medical Faculty, Family Medicine Department, İzmir, Turkey

²Dokuz Eylül University, Medical Faculty, Department of Plastic and Reconstructive Surgery, İzmir, Turkey

³Public Health Center / Balçova / İzmir, Turkey

Aim-INTRODUCTION: Bone fractures in elderly can commonly cause not only treatment complications but also movement limitations. One of complications is the pressure wounds caused by plasters used. Its treatment takes a long time, comorbidity and the aggravation of current conditions in addition to limited activity leads difficult in follow-up and consultations.

CASE: An 85 year old woman had fall on her left knee and brought to the emergency room of a medical school. It is learnt that two years ago she had a total hip replacement for her right femur fracture, additionally also had neuropathy. She was in good condition and her vital signs were stable. She had limited movement on left knee in physical examination. X-rays showed patella fracture and diagnosis during orthopaedic consultation was "slightly dislocated fracture". Long leg plaster was preferred instead of surgery as treatment. She was informed about compartment syndrome. When the plaster was removed a 3x2.5cm black, painful lesion was observed in the left heel of the patient; she was then referred to the plastic surgery and reconstruction department (PSRD). Upon the suggestions of PSRD; water extract of triticum vulgare, cream containing ethylene glycol and monophenyl ether and rifamycin were prescribed for daily dressing. She was followed up by a family physician (FP). Due to her limited mobility PREC consultations during dressing were usually achieved by technology use. Pictures of pressure wounds taken every 10 days were shared with the PSRD physician via electronic media. Debridement and follow-up period lasted about 5 months. The patient regained her health without any surgical intervention by the multidisciplinary approach of FP and PSRD physician.

Discussion-CONCLUSION: especially limitation of elderly movements due to their comorbidity can restrict effective follow-up. Similar patient-centred approaches via current technologies can be developed for consultation process between FPs and specialists.

water extract of triticum vulgare, cream containing ethylene glycol and monophenyl ether

PressureWound-2

Debridement-cream containing ethylene glycol and monophenyl ether and rifamycin

PressureWound-3

Debridement and follow-up period lasted about 5 months. The patient regained her health without any surgical intervention by the multidisciplinary approach of FP and PSRD physician.

P-0532

Evaluation of the health status and driver characteristics of elderly individuals

Hasan Kurşun, Mehmet Özen

Department of Family Medicine, Antalya Training and Research Hospital, Antalya, Turkey

Background & AIM: Elderly population in the world is increasing. The traffic problem is also increasing and affecting everyone's daily life. The driving abilities of the elderly are weakened and they encounter more problems. The aim of the study is to examine the driving characteristics of the elderly and effects of chronic diseases on it.

METHOD: 301 volunteers over the age of 50 who were referred to the family medicine outpatient clinic of a training and research hospital and agreed to participate in the study were included to the study. Participants were administered the 40-item questionnaire. SPSS 18.0 software package was used for data analysis.

RESULTS: 55.1% of respondents were male and 44.9% were women. Average age was found to be 62.1 ± 7.5 ; and 35.5% were over 65 years old. 81.1% of the participants had the diagnosis of at least one chronic disease; 39.9% had hypertension, 27.6% diabetes mellitus, 19.3% goiter, 8.6% hyperlipidemia, 4% coronary artery disease and 13.3% had other chronic diseases. 33.9% had never driven vehicle, 35.2% are active drivers and 30.9% had left to drive for various reasons. To stop driving due to attention deficit disorder were more common in over 65 years old group. Difficulty in driving due to reduction of visual function and joint pain had been identified. Only 12 participants had traffic accidents in the last five years.

CONCLUSIONS: Family physician should keep on mind that every elderly patient may be an active driver, and evaluate driving abilities. Periodic inspections of elderly drivers who have chronic diseases should be more frequent and the necessary controls must be done. Safe driving recommendations and when necessary, the decision of leaving the driving for elderly drivers may be life-saving.

Keywords: Elderly people, health status, driver characteristics

P-0533

Social Isolation Among Patients Taking Home Care Services And Their Caregivers

Güzel Dişçigil, Mehmet Aydın

Adnan Menderes University Medical Faculty Department of Family Medicine, Aydın, Turkey

Introduction and AIM:

Home care services (HCS) are needed to meet the health and care requirements of the increasing elderly and disabled population. In this study, we aimed to reveal the overall profile, and social problems face at during the presentation of services, the level of dependence in daily life and the problems encountered by caregivers of the patients taking home health and care service in Aydın province.

MATERIAL-METHOD:

Study was designed as cross sectional and descriptive. Face to face surveys and daily life activity scales were applied between June-December 2013. The demographic data, social problems that they had encountered were asked to patients and caregivers.

RESULTS:

Of the 451 patients, 303 (%67,2) were women, mean age was 70,5 years. The number of the bedridden was 192 (%42,6), and t rate was higher among women. Level of dependency; severe and moderate functional deficiency were 267 (%59,2) and 131 (%29,0), respectively, while there were 219 (48.6%) semi-dependent and 177 (%39,2) dependent patients. The dependency levels increased by the advancing age. Approximately, two thirds of the patients mentioned that they feel themselves isolated from life. The most frequent mentioned perspective for themselves were home ridden (n=103, 22.7%), immobile (n=57, 12.6%), life is boring (n=49, 10.9%), frustrated (n=46, 10.2%) respectively.

The 402 (%89,1) of home caregivers were women and the mean age was found to be 52,6 years. An important part of them (n:93; %20,7) had got a diagnosis related to anxiety while other common social problems were mentioned as inability of time allocation to nobody (n:40; %8,8) and to themselves (n:24; %5,3).

CONCLUSION:

The scope of the services should be built up by other social components (social activities, social support programmes and etc.). Besides health support, a comprehensive home care service model covering social and public supports should be developed.

⁵Altinyayla ASM, Altinyayla, Sivas, Turkey

⁶Department of Haematology, KBU Karabuk Educational and Research Hospital, Karabuk, Turkey

INTRODUCTION: Malnutrition is common problem in geriatric patients living alone. Bullous pemphigoid is a chronic, inflammatory, subepidermal, blistering disease. Geriatric patients with bullous pemphigoid togetherness malnutrition is a factor of morbidity and mortality.

CASE: Seventy nine years old woman. Right tibia fracture has occurred after an house accident. Crural plaster was applied due to fixing the proximal articulations. Supracondylar of distal femur was cut in order to circulation problems developed in the inferior extremities. Diffuse bullous pemphigoid was developed owing to inadequate homecare and starvation. When the patient came to our institution right leg amputated and was cachectic. Body parameters of the patient is as follows; body mass index 12.1 kg/m², long mini nutritional assessment 18.5 and Katz activities of daily living scale is 14 (figure 1 and 2). Parenteral hydration and protein density nutrition protocol was given. Wound care supported by moisturizer and containing arginine-hydroxy methylbutyrate-glutamine amino acid and locally corticosteroid. Psychotherapy and sertraline 50 mg. per day was applied simultaneously. After treatment bullous lesions decreased and parameters were changed as follows; body mass index 16.6 kg/m², long mini nutritional assessment 20 and Katz activities of daily living scale is 16 (figure 3 and 4).

CONCLUSION: Insufficient postoperative home care can cause many complications in geriatric population. In spite of difficulties of co-morbid states in these group, adequate care can reverse the severe problems and can cure shown as like impossible.

RS3PE case report: the family doctor's role

Ana Catarina Carvalho

Unidade de Saúde Familiar Flor de Sal, ACeS Baixo Vouga (Aveiro, Portugal)

Background & AIM: Remitting seronegative symmetrical synovitis with pitting edema syndrome (RS3PE) is a mostly geriatric disorder. It consists of an acute symmetric polyarthritis and edema of the dorsum of the hands, and can be the inaugural presentation of various rheumatic and neoplastic conditions. The diagnosis is not obvious, as it is rare and its cause may be very distant to its manifestation. It usually responds to corticosteroids, which can be a problem in older, polymedicated patients. This case report intends to evoke this clinical entity and point out the family physician's role in its approach.

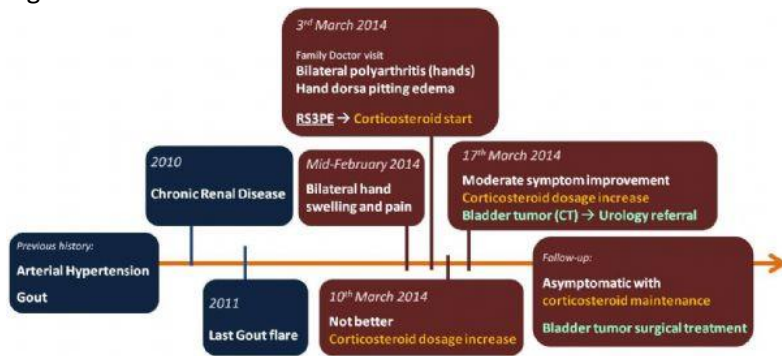

METHOD: Case report based on the family doctor's consultation notes taken during the year 2014 in the patient's clinical file.

RESULTS: A 73-year old male with history of gout, arterial hypertension and chronic renal failure, visited his family doctor complaining of bilateral hand swelling and pain that had suddenly started 2 weeks before, without any other symptoms. The examination showed a symmetric polyarthritis of both hands, with pitting edema of the dorsum. The blood tests showed a negative rheumatoid factor, low uric acid and raised C reactive protein levels. After a progressively higher dose corticosteroid therapy was initiated until obtaining a favourable clinical response, further investigation was started. Thoracoabdominal computed tomography revealed a bladder tumor which motivated referral to Urology department in an Oncology Hospital. Corticosteroids had to be continued, as lowering attempts led to reactivation.

CONCLUSIONS: The family doctor should be the patient's first point of access to the healthcare system. The knowledge of the patient's personal and family history, the possibility of close follow-up and the extremely diversified continuous education provides him the tools to successfully approach this problem. Due to its potential paraneoplastic nature, clinicians should be aware of this condition in ageing population, to promptly proceed to the necessary investigations.

“analyzing of home care services in Tokat”

Mehtap Taşova¹, Nagihan Yıldız Çeltek¹, Ufuk Ünlü¹, Osman Demir², Gülseren Oktay¹, Ramazan Tetikçok¹, Mesut Şengül¹, Tuğçe Çamoğlu¹

¹Department of Family Medicine, Gaziosmanpaşa University, Tokat, Turkey

²Department of Biostatistics, Gaziosmanpaşa University, Tokat, Turkey

INTRODUCTION: Home care service is structuring and developing health service in our contry and many countries. The growing need for home care services is due to rising age of the population, disability, chronic illnesses and accordingly rising health costs. In this study, it is aimed to evaluate on giving home care service in Tokat and to detect that which needs are satisfied by this services

MATERIALS-METHODS: In our study, 422 registration and follow up forms of patients who following by Tokat State Hospital and Tokat Public Health Instution Homecare Department, are analyzed, retrospectively. Data are analyzed via SPSS program. Numeric data are analyzed via single direction variance analysis, crosstab and chi-square test.

RESULTS: Regarding patients, it is detected that 252(59,7%) were female, 170(40,3) were male and average of age was 69,4. 78,6% of patients have social security. 237 patients were bedridden, 163 patients were semi-bedridden. Routine control visiting rate was 54%, visiting rate for prescription was 32,5%, visiting rate for medical workup was 23,5%. Average of visit number was 5,14. 295 patients (78,7%) have chronic illnesses. Most frequent illnesses among these chronic illnesses are norologic diseases(72%), hypertension(49,7), diabetes (25,1).

CONCLUSIONS: The growing need for support therapy fort o raise the life quality is due to increasing elderly population. All in all patients getting home care services, it is seen that most part of these patients are home bound. For this reason, home care services must be continuous updated and edited in the direction of patients' needs.

Social networks and digital technologies as new tools in the management of Alzheimer's disease

Manuel Linares, Hector Puente, Eva Baonza, Tomás García, Jaime Domingo
People Who Global

BACKGROUND-AIM: Social networks, digital patient forums and all digital technologies for patients are becoming essential elements in medicine today. However there are still few studies that reflect how patients behave in the media, how they use new technologies and especially how these forums can help to improve health. In addition, the medical professional still perceive with some skepticism the usefulness of these resources for clinical practice.

The aim of this study is to present the usefulness of a digital health platform dedicated to Alzheimer's disease
METHODS: Through the use of People Who website, an online platform present in several European countries aimed at patients and their closest environment, for all the people who live with Alzheimer's disease, who are interested or who care for these patients. From a considerable sample with more than 2282 users we combine quantitative and qualitative analysis (triangulation of methods and research techniques) aiming to outline the complex structure of relations on health platforms. We aspire to achieve structural representativeness by using a sample of users which accurately reflect the whole spectrum of profiles available in digital communities (structural universe)

RESULTS: We have made a complete description of the Alzheimer community and socio-emerging trends (age, sex, geographic distribution of the different profiles of caregivers) We also have identified what are the most viewed and rated by users or contents which are the socio-emerging trends, the main types of care for those wondering. The qualitative analysis of user feedback indicates that the platform has helped to prevent the caregiver burnout

CONCLUSIONS: A digital place to talk, share experiences, keep control over the illness and stay informed is a useful tool for people suffering from Alzheimer's disease and their caregivers. Provide a data center with useful resources can be an effective action in this context for patient empowerment

Background and AIM: The prevalence of malnutrition in elderly people is generally high. A relation has previously been demonstrated between functional and nutritional status. Determining nutritional and functional status of home care patients is essential for establishing programmes to prevent mortality and morbidity. The aim of this study was to assess the relationship between nutritional and functional status of home care patients registered to Muğla Sıtkı Koçman University Training and Research Hospital Home Care Unit in Muğla province (Turkey).

METHOD: This cross-sectional study was conducted with 143 home care patients registered to home care unit and a part of comprehensive geriatric assessment project conducted in this unit. The nutritional status of participants was assessed through the Mini Nutritional Assessment (MNA) full form test. MNA provides a classification according to individual's nutritional status. Functional status is determined with Barthel Index (BI). The BI is used to make a classification according to individual's performance and functional dependence in basic activities of daily living such as faecal or urinary incontinence, the help needed with grooming, toilet use, feeding, and bathing. Sociodemographic factors and disease related data were also obtained from the participants. Groups of malnutrition were compared by using mean MNA scores.

RESULTS: 143 elderly participated to the study. Average age was 82.1 ± 7.4 (Min:65, max:103). The prevalence of malnutrition was 26.6% and risk of malnutrition was 57.3%. 31 (21.7%) of the participants were smoking. The BI classification was as follows: 33.6% (n = 48) totally dependent, 42.0% (n = 60) severely dependent, 24.5% (n = 35) moderately dependent. No participants were found as slightly dependent or independent. MNA and BI were significantly associated.

CONCLUSIONS: Our data showed high prevalence of malnutrition and risk of malnutrition among elderly home care patients and positive relation between MNA and BI.

Assessment of a brief community intervention for patients with insomnia: A "before and after" study

Rogelio Argueta Armenta¹, Ovidiu Nicsa¹, Cristina Moliner Molins¹, Imma Campamà Tutusaus¹, Carmen Delgado Diestre¹, Silvia Soriano Diestre², José Antonio García Ramos², Miriam Rey Seoane¹, Yolanda Alonso¹, Neus Parellada¹

¹EAP El Castell 1, C Marconi S/N Castelldefels 08860 Barcelona España

²H. Ayuntamiento de Castelldefels

OBJECTIVE:

- Analyze reduction of sedative-hypnotics after community intervention.
- Identify characteristics of patients attending the conference, patients diagnosed with insomnia and those with treatment for sleep disorders.

Methodology

Design: Cross-sectional descriptive study: Initial assessment and assessment after 6 months.

Study subjects:

Participants in the workshop: "Insomni: dormim bé", in the "XXXII Jornades Gent Gran" of the City Council of Castelldefels (> 65 years of age).

Workshop: 1.30 h. Theoretical explanation, variables, pharmacological treatment, relaxation exercises using audiovisual support.

Variables:

Medical history reviews, diagnosis code for insomnia, start of pharmacological treatment, subsequent check-up, visits to physician and nursing visits, interruption of treatment, Pittsburg sleep quality index, level of satisfaction.

RESULTS:

Out of 110 attendees, 40 responded to telephone questionnaire and consented to clinical overview.

95% (38) women and 5%(2) men. Average age: 72 years. 27.5% diagnosis code for insomnia and 55% treated with sedative-hypnotics.

After the conference/workshop 10.5% (4 attendees) consulted a physician again.

31.8% (7) stopped treatment, 2 of them had a diagnosis code.

47% were treated with sedative-hypnotics in May, 35% collected treatment from pharmacy. After 6 months,

47.5% of patients had treatment prescribed, 35% collected it.

Average score regarding Pittsburg Test: 8 in women and 3.5 in men. A score lower than 10: good quality of sleep, and higher than 11: poor quality of sleep.

27.5% obtained a higher or equal score to 11 points and 72.5% - 10 or lower.

Out of 22 patients being treated, 9 with a diagnosis code for insomnia, 13 without, statistically significant "P"-0.038.

CONCLUSIONS:

Reduction of sedative-hypnotics and consultation after conference/workshop.

Only 27.5% of participants with a diagnosis code, 55% had sedative-hypnotic treatment.

Average percentage from Pittsburgh Test: poor quality sleep that correlates with the same percentage with a diagnosis code of insomnia.

Full satisfaction about the conference/workshop.

Keywords: Insomnia, sedative-hypnotics, Pittsburg sleep quality index

Tackling polypharmacy in older adults: A compilation of systematic reviews for the development of an electronic decision support tool

Roman Schlager¹, Anna Renom Guiteras¹, Yolanda Martinez², Ilkka Kunnamo³, Andreas Sönnichsen¹, PRIMA-eDS Review Group⁴

¹Institute of General Practice and Family Medicine, University of Witten/Herdecke, Witten, Germany

²Primary Care Research Group, University of Manchester, Manchester, UK

³Duodecim Medical Publication Ltd., Helsinki, Finland

⁴Finland, Germany, Italy, UK

BACKGROUND AND AIMS: There is a need to carefully weigh the risks and benefits of medication in older adults with multimorbidity and polypharmacy. Aims are: 1) to identify the evidence on risks and benefits of drugs commonly used in older adults; 2) to provide recommendations on their use, which can be incorporated into an electronic decision support tool (eDS-tool) aimed at supporting general practitioners to reduce inappropriate prescriptions.

METHODS: The PICOS-framework was used for the development of the search terms. Searches 1 and 2 identified systematic reviews (SR) and meta-analyses in the Cochrane Database of Systematic Reviews and DARE, and in MEDLINE, EMBASE, HTA and IPA, respectively. Search 3 identified clinical trials and observational studies from SRs not included in searches 1 and 2 but containing eligible studies and from the databases considered in search 2. Selection of studies, data extraction and quality appraisal were performed by two reviewers independently. Based on the evidence found the recommendations were developed using the GRADE methodology.

RESULTS: n = 21 SRs have been performed. In general, the amount of studies included and the quality of the evidence are low. So far, n = 46 recommendations for the following drugs have been developed: metformin, sulfonylureas, gliptins, glitazones, non-steroidal anti-inflammatory drugs, statins, beta-blocking agents, Vitamin K antagonists, new oral anticoagulants, nitrates, calcium channel blockers, thiazides, platelet inhibitors, high ceiling diuretics, insulin, digoxin, opioids and proton pump inhibitors.

CONCLUSIONS: Our work reflects a general lack of high quality evidence regarding drug treatment of older adults with multiple conditions. Recommendations have been checked by external review and have been integrated in the eDS-tool. The eDS-tool is currently tested in a randomized controlled trial with clinically relevant endpoints. This study is part of the 7th Framework European Project PRIMA-eDS* (Grant No. 305388-2).

analysis of geriatric patients admitted to the emergency clinic and accepted

Mehmet Halis Tanrıverdi, Hamza Aslanhan, Necmi Arslan, Ahmet Yılmaz, Erkan Kıbrıslı
Department of Family Medicine, Medicine Faculty, Dicle University, Diyarbakir, Turkey

AIM: Geriatric patients are the entrances to the hospital emergency department of geriatric patients could deteriorate quickly because they can be heard and intensive care needs. In this study, the incidence of hospitalizations in patients 65 years and older admitted to the emergency department and aimed to determine the clinical cases were hospitalized.

METHOD: 39 737 geriatric patients were admitted to Dicle University Faculty of Medicine emergency department the between 2010-2014. Services provided 13,681 patient admissions files were analyzed retrospectively.

RESULT: 13681 from 39 737 geriatric patients admitted to the emergency department (34.4%) were hospitalized. 6612's of 13681 patients (48.3%) were female, 7069 to (51.7%) were male. Women's average age 77.46 ± 8.2 , mean age of the men was found to be 75.94 ± 7.4 . Patients most often in 2010 were found to be hospitalized (Figure 1).

When patients were examined we have identified the most frequent admission services Cardiology service and intensive care (Figure 2).

CONCLUSION: One out of every three geriatric patients admitted to the emergency clinic were hospitalized. This large proportion of patients in has created divisions such as cardiology, internal medicine, breast and general surgery. In geriatric patients, problems that require surgery and intensive care needs are seen as favorites. The show approaches specially trained staff and experts of the urgent problems of the elderly population will lead to faster and higher quality health service.

Department Of Family Medicine, Dışkapı Yıldırım Beyazıt Training and Research Hospital, Ankara, Turkey

Background & AIM: Pressure ulcer (PU) is a frequently seen morbidity in home care elderly population. This study aimed to evaluate the nutritional status and biochemical parameters of home care elderly patients with PUs and without PUs.

METHODS: This descriptive study was carried out at Dışkapı Yıldırım Beyazıt Training and Research Hospital Home Health Care Center in 2015. In our study all patients (308) were home care elderly patients. 61 of them were in group PU (with PU), 247 of them were in group non-PU (without PU). All data were gathered from patient files. Blood samples were collected at home visits. Nutritional status was assessed by Mini Nutritional Assessment Short Form (MNA-SF) and Full Mini Nutritional Assessment (Full MNA).

RESULTS: The mean age was 79.0±8.5(min:65,max:99) years. In group PU and group non-PU 68.9%(42) and 63.6%(157) were females, respectively. Mean BMI of group PU(22.1±3.8 kg/m²) was lower than group non-PU(24.6±5.0 kg/m²)(p<0.05). There was a statistically significant difference in terms of mean MNA-SF score and Full MNA score between groups(p<0.001)(Mean MNA-SF score in group PU:6.0±3.0, in group non-PU: 9.3±3.3; mean Full MNA score in group PU:11.9±4.7, in group non-PU: 18.9±5.7). When the patients were evaluated with Full MNA in group PU, malnourishment was found in 49 patients(80.4%), risk of malnutrition in 11 patients(18.0%) and 1 patient(1.6%) had normal nutritional status. There was a statistically significant difference in terms of mean serum total protein and serum albumin levels between groups(p<0.001) (Mean serum total protein in group PU:6.2±0.6 g/dl, in group non-PU: 6.7±0.6 g/dl; mean serum albumin in group PU:3.1±0.5 g/dl, in group non-PU: 3.6±0.5 g/dl). Also mean hemoglobin levels in group PU(11.9±1.7 g/dl) were statistically lower than group non-PU(12.5±1.6 g/dl)(p<0.05).

CONCLUSION: The high prevalence of malnutrition among patients with PUs in our study points out a need for raising awareness for nutritional screening.

Correlation Between Medications and Falls in the Elderly People

Ayse Semra Demir Akca¹, Nejat Demircan¹, Fatih Akca², Funda Beyazçicek¹, Raşan Bulut¹, Tugba Beyazçicek¹

¹Department of Family Medicine, Bülent Ecevit University Faculty of Medicine, Zonguldak, Turkey

²Uzun Mehmet Chest and Occupation Hospital Zonguldak, Turkey

Background: Falls are an important public health problem for older adults, resulting in significant morbidity and mortality. Falls are prevalent among older adults and can lead to serious injury, loss of independence, hospitalization, nursing-home admission, and increased healthcare costs. Environmental hazards, medications, vision problems, and impairments in strength, gait, or balance can increase fall risk

AIM: One of the most serious consequences of polypharmacy is falling down of the elderly. In this study the correlation between polypharmacy and falls in the elderly people frequently encountered in the hospital.

Patients and METHODS: Falling down stories and polypharmacy regimes of elderly people have been examined and the relationship between these two data have been established with the SPSS program. The patients were divided into two groups: Both groups were compared in terms of demographic data, diagnosed chronic diseases, medication and habits.

RESULTS: The study is in process. Results will be discussed at the congress.

Keywords: Aged, polypharmacy, falls.

• Development of Dementia Care in Community

Tatjana Cvetko

Department of Family Medicine Medical Faculty Ljubljana, Slovenia

BACKGROUND: Dementia is still poorly recognised in the community. After diagnosis people are looking for help in organizing the care of patients with dementia in various health and social services. Alzheimer organization encourage caregivers attending the self-help groups and can become an important source of organized assistance in the community, where people can get help and information about assistance in the community.

AIM: to show the development of organization of selfhelp groups, meetings and other interventions to offer psychosocial, informational and professional support in society in the light of needs of aging population and people with dementia.

METHOD: Review the development of organized care and learning about dementia in the community from self-help groups to one-day school on dementia.

RESULTS: Presentations of activities which have the association spread over the years throughout the region from the urban to the rural environment to help people with dementia.

- Selfhelp groups. 14 years, last years in 4 location, 10 meetings/year – per group,
- Annual meetings with lectures on dementia for lay public and professionals (14 years)
- One-day school about dementia – parallel program for caregivers and patients with dementia. Caregivers learn about dementia, get some practical skills and information, patients attend the program different activities in daily care (4 years)
- . Lectures for professionals about recognition and treatment of dementia, with particular attention on supporting families caring for patients with dementia at home
- . Alzheimer cafe - meetings in public area with talks about dementia for lay public
- . Information about dementia with leaflets, announcements in local media and public events

CONCLUSIONS: Selfhelp groups are not only a constant and important source of information and assistance in caring for patients with dementia, but also play in important role in learning an teaching process about dementia in community.

Keywords: dementia caregiving, selfhelp groups, community learning on dementia

Dementia Diagnosis Of Primary Care Physicians In Istanbul

Kübranur Demir¹, Pemra C. Unalan¹, Fatma Dindar¹, Yeliz Özendi¹, Ferdinando Petrazzuoli²

¹Marmara University School of Medicine, Department of Family Medicine, Istanbul, Turkey

²Department of Clinical Sciences in Malmö, Centre for Primary Health Care Research, Lund University, Malmö, Sweden

INTRODUCTION: Dementia is one of the most disabling and a disease characterized by impairment of cognitive functions, changes in personality and diminished activities of daily living. Most never receive a diagnosis, even in high-income countries, only 20–50 % of dementia cases are recognized in primary care. There are many barriers to prompt and accurate diagnosis of dementia in primary care. The aim of this study was to investigate the readiness of the primary care physicians (PCP) with suspected or diagnosed dementia.

MATERIAL-METHOD: A total of 30 primary care physicians who were both GP and Family Physician, were applied a survey electronically form with 7 close-ended questions and asked for a dementia case history from the participants own practice. Case histories were used to raise an outline of the management of “the dementia suspected patient”.

RESULTS: A total of 22 (N=30) replied, 12 were females, 15 were GPs, 12 believe in that the secondary care physicians were officially responsible for the diagnosis of dementia, but 10 believe in both of the primary and secondary care physicians. Only 2 of the PCP expressed that they can try to establish a diagnosis of dementia on their own and 16/22 expressed, rarely. Nineteen of the participants told that should refer the patient to the secondary care specialist. Easy and short dementia tools and longer consultation time were required most by the GPs to detect dementia better. Only 4/22 physicians wrote the story of a dementia case from their practice. One physician mentioned no previously diagnosed dementia patient.

CONCLUSION: In Turkey among primary care physicians, limited knowledge, a gap of shared care protocols and practical guides, difficulties with the referral pathways, their pessimism about the effect of the treatment and diagnostic uncertainty can lead to timely delays in diagnosis and management of people suffering dementia.

Family physician approach to peripheral artery disease: An old patient

Ülkü Yıldız¹, Nil Tekin², Mehtap Kartal³

¹Department of Family Medicine, Çukurca State Hospital, Hakkari, Turkey

²Department of Family Medicine, Narlidere Residential and Nursing Home, İzmir, Turkey

³Department of Family Medicine, Dokuz Eylül University, Balçova, İzmir

INTRODUCTION:

Peripheral artery disease (PAD) is an atherosclerotic disease being a significant reason of cardiovascular morbidity and mortality frequency of which increases especially at later ages. In this study, revealing the family physician approach to PAD in an old patient staying at the residential home was aimed.

CASE:

77-years old male patient staying at the residential home applied to the family physician with the complaints of swelling of right foot, loss of sense, loss of strength continuing for 2 months. In the medical history of the patient, HT, angiography-stent, KOAH, DM, bladder cancer are reported. The patient smoked 60 packages/year and alcohol consuming is at the level of social drinker.

In the physical examination of the patient, edema is observed in right foot, pulses of right lower extremity are weak. As the pre-diagnosis, right dural nerve root pressure and following Ankle Brachial Index (ABI) measurement, PAD was considered and cardiovascular surgery consultation was asked. Femoral pulses were seen in the consultation but distal pulses were not present and loss of dorsiflexion was found and in the result of CT angiography, right superficial femoral artery (SFA) was reported as totally occluded, left main femoral artery had 70% stenosis, left SFA was reported as totally occluded. Due to the diagnosis of KOAH, the operation (femoropopliteal bypass) could not be performed and medical therapy and varsity socks were recommended. PAD should be considered for HT patients and screening with ABI measurement should be carried out for the early diagnosis and improvement of prognosis should be aimed. Non-presence of symptoms in the patient and progressing with atypical symptoms results in ignoring diagnosis of PAD. Family physicians should be aware of the fact that PAD is a problem of community health and patients in the risk group should be evaluated accordingly.

Is it merely a sciatica pain?

İşık Gönenç¹, Emine Zeynep Tuzcular Vural¹, Şirin Yaşar²

¹Haydarpaş Numune Research and Training Hospital, Family Medicine

²Haydarpaşa Numune Training and Research Hospital, Dermatology Department

Varicella Zoster Virus (VZV) is the etiologic cause primarily of varicella (chicken pox infection) and its reactivations presenting as herpes zoster (shingles).

Older age, altered cell-mediated immunity, malignancies, chronic diseases are common risk factors for reactivations.

A 76-year-old immune competent woman presenting with burning lower back pain, right sciatica pain, allodynia in the right gluteal area, malaisedifficulty in walking and giving way in the right knee and developing painful, itchy and tingling grouped erythematous plaques with vesicles on the right gluteal and antero lateral aspect of her right thigh and leg after two days is described. The giving way of the knee and difficulty in walking suggests motor nerve involvement L4-5 innervated muscles.

The distribution was consistent with the L4-5 dermatomes, and a diagnosis of herpes zoster was made. The patient was prescribed valacyclovir hydrochloride, 500 mg three times daily for five days, analgesics and dressing as well as plenty of bed rest. The woman had a history of bilateral cataract operations one week apart 20 days ago, and described a right lateral malleolus fracture as a result of an ankle sprain a week ago.

CONCLUSION:

Clinicians should consider the possibility of herpes zoster especially in the elderly suffering from intractable pain projected in dermatome zones after recent trauma and stress in order to start treatment as soon as possible. The vaccine against herpes zoster should be offered to all elderly people without any contraindications at the patient's first clinical encounter.

Smartphone Usage, Obesity, and Lifestyle Habits of Children and Adolescents in Korea

Seongho Han¹, Yj Park¹, Js Park¹, Js Choi²

¹Department of Family Medicine, Dong-A University, Busan, Korea

²Department of Family Medicine, Kosin University, Busan, Korea

BACKGROUND: Due to its highly addictive characteristic, smartphone use can reduce physical activities and cause unhealthy lifestyle habits, which leads to obesity. This study aimed to investigate the correlation between smartphone usage and obesity related factors.

METHODS: We visited four primary schools in Busan City in Korea for the completion of questionnaires for 11~12 years-old students. Out of 667 students, 240 underweight students were excluded, while 427 students were classified into average-weight group and overweight/obese group. The hours of smartphone use, relationship between Smartphone Addiction Scale and obesity, and correlation with obesity related factors were analyzed.

RESULTS: T-test was conducted based on the hours of smartphone use. The result showed that the students who used smartphones for 2 or more hours had significantly higher BMI than the students who did not. ($p < 0.05$) The result of the logistic regression analysis showed more students who used smartphones for 2 or more hours daily, watched TV for 120 minutes or more, have taken their last meal later than 7 pm, watched TV while eating, and ate fatty foods. Moreover, the students in the potential risk group among the students who used smartphones tend to have their last meal later than 7 pm, eat excessively, and watch TV while they consume fatty foods, snacks, or drinks.

CONCLUSION: The smartphone usage time and smartphone addiction are significantly related to the obesity factors in children and adolescents.

Globalizaion and the Surge of Dengue

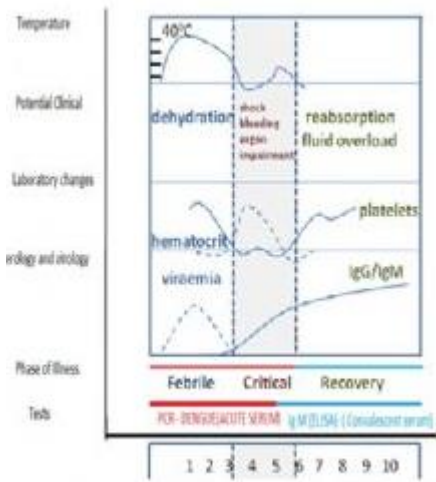

Ani Bodoutchian, Stacy Emile, Heera Motwani, Andrea Caracioli, Vinod Kumar
North Shore Long Island Jewish

Globalization and travel has made our world a much smaller place. Diseases that were once endemic to only a specific region of the world are now in our hometown. Today about 2.5 billion people, or 40% of the world's population, live in areas where there is a risk of dengue transmission. Dengue is endemic in at least 100 countries in Asia, the Pacific, the Americas, Africa, and the Caribbean. Information was gathered from existing recommendations from the CDC (Centers of Disease Control and Prevention) as well as other research sites were explored for their guidelines.

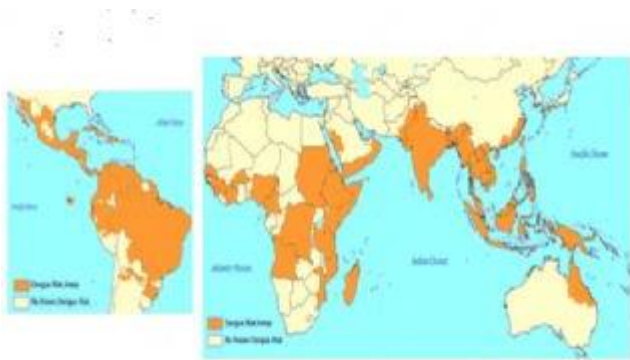

Effective disease prevention must have several integrated components, including active laboratory-based surveillance, emergency response, and education of the medical community to ensure effective case management, community-based integrated mosquito control, and effective use of vaccines when they become available.

P-0550**Comparison of obesity in children attending to a governmental primary school versus a private college**

Hakan Demirci, Beyza Demirbaş, Ali Candar, Fatih Çiftçi, Esra Beşir Mahsun, Yasin Güçlü, Nevruz Yıldırım, Salih Metin, Hayri Bozkurt

Department of Family Medicine, Sevket Yilmaz Training and Research Hospital, Bursa, Turkey

AIM: The frequency of private colleges is about 2-5% in Turkey. Families preferring private schools certainly belong to higher socio-economic power. Although private schools continues education full time period, governmental schools serve in part time period. Children attending private schools have their lunch at school on the other hand the others go home for lunch. In the present study we aimed to compare obesity in children in these two different categories of schools.

METHODS: There were 590 students in the governmental school and there were 171 students in the private school we visited. Height and weight measurements were made by assistant family physicians. Heights were measured in standing position and weights were measured while wearing light clothing. Ages and genders were noted. Educational status of the parents was also asked.

RESULTS: Age and gender distribution were similar. Educational status of parents who had a child in private college was statistically significantly higher compared to the other group. There were 79 obese students (13.3%) in governmental school while there were 30 obese students (17.5%) in private colleges ($p=0.000$).

CONCLUSIONS: Obesity was more prevalent among private college students. Meals served at private colleges may be a factor that raises risk of obesity. Intensified educational material, more frequent exams performed and higher expectations of families from students attending colleges may aggravate stress and hence obesity.

Keywords: private college, governmental school, obesity, stress, child

P-0551**Global Trends in the Incidence of Malaria**

Ani Bodoutchian, Donald Leveille, Tamas Ungar, Keasha Guerrier, Ebikaboere Youkedebah, Maureen Grissom
Department of Family Medicine, North Shore - LIJ School of Medicine Southside Hospital, New York, USA

One of the very well-known preventable as well as treatable diseases of the developing world is Malaria. It is a location-specific infectious disease transmitted by mosquitoes to humans and is influenced by environmental, vector, parasite, and host factors. By far, the illnesses that pose the most frequently encountered risks to western travelers to the tropics are vector-borne illnesses such as Malaria.

Due to many factors including increase access to travel in developing countries, as well as globalization, there appears to be an increasing number of cases of malaria encountered in areas of the world that have been understood to be malaria-free. We therefore set out to analyze available data concerning global trends in the incidence of Malaria over the years.

Assessment of Fluids Intake Among Health professionals

Yasser Yaghi¹, Ahmad Hesso², Nancy Maan², Maher Hamzeh³, Wajih Zaiour³, Shadene Yaghi⁴

¹Beirut Arab University, Beirut, Lebanon

²Hammoud Hospital -UMC, Saida, Lebanon

³Health Medical Center, Saida, Lebanon

⁴American University of Beirut

INTRODUCTION:

Water constitutes more than 65% of the body weight in a healthy adult male and 55% of the body weight in a healthy adult female. It is essential for human life and a co-factor in all chemical reactions that occur in the body.

AIMS:

To assess fluids intake among hospital staff in order to maintain a healthy level of hydration.

Subjects and METHODS:

168 members of the staff of a 350-beds general hospital and university medical center were interviewed by 2 senior residents and the hydration calculator index was used to calculate the amount of fluids taken per day. Staff members were subdivided into 4 groups: specialists, residents, nurses and clerks. Height, weight, gender, age, activity level and daily calorie intake from fluids was calculated for each staff member.

Analysis of data collected was performed using SPSS-17 soft ware program

RESULTS:

Nurses comprise the widest profession reviewed (80/168). Female to male ratio was 8/6. Activity level was almost rare 47% among all groups. Clerks and nurses tend to drink fewer fluids than physicians. 63% of the residents drink enough fluids daily. Males tend to drink more fluids (64%) than females (41%). The daily calorie intake from fluids was the highest among residents (104.97 Kcal).

CONCLUSION:

Increasing the number of water coolers and dispensers (mains-fed and bottle fed) in health facilities might encourage and improve hydration among health care professionals and that makes good economic sense and brings well being and better quality of work and life.

Knowledge and attitude of Primary Care Health Professional in connection with The European Code Against Cancer

Esperanza Maria Romero Rodriguez¹, Luis Ángel Pérula De Torres², Fernando Leiva Cepas¹

¹Family and Community Medicine Teaching Unit

²Maimonides Institute of Medical Research IMIBIC/ Reina Sofia Hospital, Córdoba.

OBJECTIVE: To evaluate knowledge, attitudes and socio-demographic aspects of the primary care professionals regarding on the European Code against Cancer (ECAC) recommendations.

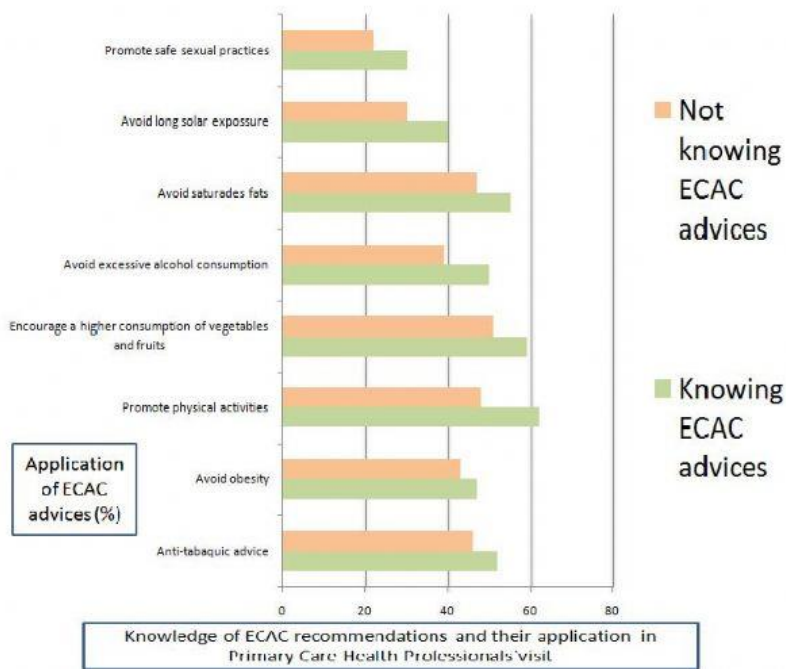

METHODS: A cross-sectional, descriptive, multicenter study was designed. Colleagues from Spanish Society for Family and Community Medicine (semFYC), health care professionals who were selected by snowball sampling and primary care providers who took part in ECAC-PC study, were enrolled. They completed an online questionnaire that collected socio demographic aspects and queries about their transmission of the recommendations of the ECAC to their patients during their clinical practice. A statistical analysis was performed, considering $p < 0.05$ statistically significant.

RESULTS: 1666 health practitioners were recruited. Their mean age was 46.5 years (SD 9.3). 74% of them were women. 83% were doctors and 11.2% nurses. 48% of them did not know the ECAC recommendations (IC95%: 45.59-50.45) and 77% were not attached to the Program of Preventive Activities and Health Promotion (PAPPS). Significant differences by age, gender, type of professional and knowledge of the ECAC were found. There was no relation to be affiliated to PAPPS or to be Resident director. Recommendations transmitted more frequently were anti-smoking counseling (36%), dietary advice (54.1%) and avoid obesity (22%).

CONCLUSIONS: The degree of transmission of the ECAC recommendations was a great deal higher in those professional who knew the ECAC, being the nursing staff the group which promoted more such activities. However, most health care professionals indicated that the percentage of their patients who adopted healthier lifestyles promoted in the ECAC was low.

Public Knowledge about Crimean Congo Hemorrhagic Fever in Albania

Marsida Krasniqi¹, Genta Nallbani², Sokol Plaku¹, Besmira Rroku³

¹Department of Healthcare Elbasan, Albania

²Department of Sport Medicine Tirana, Albania

³Health Department Caritas Tirana, Albania

OBJECTIVE: The aim of this study is to assess the level of knowledge about the Crimean Congo hemorrhagic fever in Albania.

METHODS: This questionnaire based on a cross-sectional survey was conducted in the period June-September 2014 in Tirana, Albania. Selection of individuals was random. A total of 1220 persons agreed to complete the questionnaire. The questionnaire was constructed from 10 questions; the first four questions were for demographic data; the rest were for knowledge toward Crimean Congo hemorrhagic fever. The data collected were recorded and analyzed. The continuous variables were presented as mean and standard deviation; categorized variables were presented as percentage.

RESULTS: This study included 42.3% males (n=516) and 57.7% females (n=704) with average age 28.3 ± 10.66 years (range 19-56). 85.9% of participants interrupted the questionnaire because they responded that they didn't have knowledge about Crimean Congo Hemorrhagic Fever. The rest 14.1% (n=170) who had heard about Crimean Congo Hemorrhagic fever, reported in 85.6% that the source of information was media and 8.8% that the source of information was the school. Regarding the cause of the disease 57.3% declared as cause the virus and 11.4% reported they did not know the cause of the disease. 43.6% of participants who had knowledge of the Crimean Congo Hemorrhagic Fever reported the disease as contagious and lethal. 63.3% answered that the way of transmitted disease was by ticks and 70.8% answered that the way of transmitted disease was by affected persons. 21.3% reported as high risk for getting the disease the farmers. While 89.3% answered that they did not know the current situation in Albania about the disease.

CONCLUSION: In conclusion, it must be said that our findings showed that the level of knowledge in the population for this fatal disease is insufficient. The information obtained by the media is not complete and accurate. We believe that an education program will help raise the level of knowledge regarding Crimean Congo Hemorrhagic Fever in Albania.

How do we control hypertension in family medicine practice?

Olivera Batic Mujanovic¹, Edina Jaganjac², Larisa Gavran³, Esad Alibašić², Munevera Becarevic⁴

¹ Family Medicine Teaching Centre of Health Centre Tuzla; Department of Family Medicine, Tuzla University, Tuzla, Bosnia and Herzegovina

²Health Centre Kalesija, Kalesija, Bosnia and Herzegovina

³Family Medicine Teaching Centre of Health Centre Zenica; Department of Health Care, Zenica University, Zenica, Bosnia and Herzegovina

⁴Health Centre Banovici, Banovici, Bosnia and Herzegovina

Background&AIM: Prevention and management of chronic noncommunicable diseases are the main goals in family medicine practice. Aim of this study was to assess the quality of hypertension care provided by family medicine team through a medical audit.

METHOD: This retrospective analysis included 70/349 randomly selected medical charts of patients with hypertension (every fifth chart from register for hypertension) at the Family Medicine Teaching Centre Tuzla. Audit record form contained questions on sex, age, blood pressure, lipid status, body mass index (BMI), creatinine and urinalysis, smoking habits, physical activity and prescribed antihypertensive drugs.

RESULTS: Prevalence of hypertension was 24.2% (349/1445). Significantly more women had hypertension than

men (75% vs. 25%; $p < 0.0001$). Majority of patients (40%) belonged to the age group 60-69 years. Mean age of patients was 66.23 ± 10.96 years. Mean duration of hypertension was 9.82 ± 7.31 years. Family medicine team showed poor compliance with established criteria for hypertension control. Blood pressure was recorded in 92.5% of charts. Controlled blood pressure had 59.5% patients. Lipid status was recorded in 80% charts. Total cholesterol was controlled in only 9.4% patients, as well as triglyceride in 20.4% patients. BMI was recorded in 92.5% patients and only 6.3% had BMI $< 25 \text{ kg/m}^2$. Smoking status was recorded in 95% patients. There were 26% smokers, 18% ex smokers and 55% never smokers. Urinalysis was recorded in 87.5% charts and creatinine in 72.5% charts. Annual ocular examination had only 37.5% patients. Physical activity was recorded in all charts (100%). Majority of patients (51%) took two antihypertensive drugs, while 6% patients used three and more drugs to control high blood pressure.

CONCLUSIONS: Results of this study showed a high prevalence of deficiencies in the quality of care for hypertension in family medicine. It indicates more effective intervention in primary health care in order to reduce cardiovascular morbidity and mortality.

"Health and new technologies: the Smartphone applications"

Paula P Rodriguez Casal¹, Ana Isabel Beiró¹, Ana Belén Piñón Gamallo¹, Miguel Alonso Montoto², Carmen Arca¹, Santiago Perez Cachafeiro¹

¹Integrated Management Area Pontevedra-Salnes. Pontevedra. Spain.

²Secondary Education Institute Frei Martin Sarmiento. Pontevedra. Spain

Objective

The aim of this study was to evaluate the use of existing applications in health and welfare of current smartphones and its contribution to the motivation of increasing physical activity (PA) by their users.

Methods

A descriptive study was conducted. An online survey was open from October to November 2013. Adults aged from 18 to 65 years who resided in Pontevedra were invited to participate.

Results

172 people were participating in the survey (mean age: 34.58 years (± 9.6)). The prevalence of smartphone users was 64.5% and 27.9% of them had installed at least one application of health and wellness. The 45.9% of respondents considered useful these applications.

Conclusion

Users of these applications did more exercise since they had these applications and they believe that apps are useful in helping them with practical exercise. This certifies the potential of the applications to support the behavior change in the PA and other lifestyle habits, resulting in a significant public health impact.

⁴Health Center Banovici, Banovici, Bosnia and Herzegovina

⁵Health Center Tuzla, Tuzla, Bosnia and Herzegovina

Background & AIM: Diabetes mellitus is associated with a significantly increased risk for morbidity and mortality. The aim of this study was to assess the quality of diabetes mellitus care provided by family medicine team at the Family Medicine Teaching Centre (FMTC) Tuzla through a medical audit.

METHODS: This retrospective study included 62/1452 medical records of patients with diabetes mellitus treated by family medicine team at FMTC Tuzla. We analyzed control of metabolic parameters for diabetes (level of blood pressure, blood glucose, HbA1C, total cholesterol, and body mass index) according to the ESC Guidelines on Diabetes, Pre-diabetes and Cardiovascular Diseases 2013, lifestyle, and prescribed antidiabetic therapy in patients with diabetes mellitus.

RESULTS: Prevalence of diabetes mellitus was 4.27%. Significantly more patients had type 2 diabetes (96.77% vs. 3.17%; $p < 0.0001$). Mean age of participants was 66.68 ± 12.4 years. Mean duration of diabetes was 9.97 ± 7.24 years. Significantly more women had diabetes than men (59.68 vs. 40.32%; $p = 0.03$). Only 11.29% patients had controlled glycaemia, while 58.06% patients had HbA1c $< 7.0\%$. All patients had normal urine analysis. Hypertension was present in 80.95% patients. Controlled blood pressure $< 140/85$ mmHg had 90.19% patients, and 75.81% patients had goal total cholesterol level. Only 17.46% patients had body mass index < 25 kg/m², while 42.80% patients were overweight, and 39.68% patients were obese. Majority of patients (72%) were physically inactive. More than half of patients were never smokers (53.22%), 22.58% were ex smokers, while 24.19% patients smoked. Oral antidiabetic therapy used 70.96% patient, 29.14% patients used only insulin, while 9.67% patients used combined antidiabetic therapy.

CONCLUSION: Result of this study showed that deficiencies in the quality of diabetes care in family medicine still exist. It indicates more effective intervention in primary health care in order to reduce morbidity and mortality in patients with diabetes.

Health Promotion Behaviours of the Future Health Care Professionals

Sevgi Özcan¹, Ali Bozhüyük², Nafiz Bozdemir¹

¹Department of Family Medicine, Çukurova University, Adana, Turkey

²Çiftlik State Hospital, Niğde, Turkey

BACKGROUND and AIM: Health science students are health care professionals and role models of the future. The aim of this study is to evaluate of health science students' health promotion behaviours.

METHOD: The sample population was composed of 801 students that attending to the health science schools (medicine (grade 1, 4, and 6), dentistry (grade 1, 4, and 5), midwifery, and nursery (grade 1 and 4)) of Cukurova University. The data was collected by an anonymous questionnaire and Health Promotion Lifestyle Profile-II scale. The 52-item scale is composed of a total and six subscales to measure behaviours in the theorized dimensions of health-promoting lifestyle: spiritual growth, interpersonal relations, nutrition, physical activity, health responsibility, and stress management.

RESULTS: Of the 60 % students were female. The mean age was 21.5 ± 2.21 (17-34) years. The mean score of Health Promotion Lifestyle Profile-II scale was at middle level (124.30 ± 17.92), the highest score was taken from spiritual growth subscale and the lowest one was taken from physical activity subscale. No significant relation was found between the age groups and the mean scores. Males got the higher score from the physical activity subscale, and females got the higher scores from all other subscales ($p < 0.05$). The health responsibility and the stress management mean scores of the students whose fathers were graduated from university were lower ($p < 0.05$). The all scores of the students attending to the medicine school were lower compared to the schools of dentistry, midwifery and nursery ($p < 0.05$).

CONCLUSIONS: Health promoting behaviours continue to take shape during their university training. Our study may be a guide for programs to improve the health promotion behaviours of health science students who are health professionals and role models of the future. Because of their curriculum includes "health promotion counseling" family medicine residents may take place in these programs.

Prevalence of Metabolic Syndrome in Patients with Psoriasis

Marco Arturo Quispe Suárez¹, Cristina Molinos Carrasco¹, Idaira Damas Pérez¹, Núria Montellà Jordana², Amparo Sancho Perpiñan¹, Ma Del Mar Ansaldo Pérez¹, Celia Tajada Vitales³

¹Primary Care Centre, Dr. Vilaseca - Can Mariner. Sta. Coloma de Gramenet, Barcelona, Spain

²Primary Care Service Metropolitana Nord i Maresme, Barcelona, Spain

³Primary Care Centre, Barri Llatí and Fondo. Sta. Coloma de Gramenet, Barcelona, Spain

BACKGROUND: Medical research shows that exist more prevalence of metabolic syndrome (MS) among patients with psoriasis.

This study aims to determine the association between psoriasis and MS, and to compare the prevalence of MS in patients with psoriasis according to severity and sex.

METHOD: A cross-sectional descriptive research was performed in a Centre for Urban Primary Care. Population: All patients with psoriasis, and patients without psoriasis matched for age and sex. Variables: social-demographic and presence of MS; in patients with psoriasis: years of evolution, severity scale as Psoriasis Area and Severity Index (PASI), monitoring and treatment. **METHOD:** interview and review of medical records. Analysis: Descriptive and calculation of OR.

RESULTS: n = 114 in both groups. The overall prevalence of MS was similar in both populations: 45.6% (95% CI 36, 46 to 54, 74) in psoriasis, 47.7% (95% CI 38, 23 to 56, 57) in patients without psoriasis. Patients with psoriasis: the majority (66%) received exclusive track by family doctors. Severity: according PASI only 2 patients (1.8%) were moderate and the rest were mild, of which 18 (15.7%) were receiving immunosuppressive or biological treatment; taking the treatment into account we could consider moderate 20 (17.5%) and mild 94 (82.5%). MS was detected in the 2 patients with moderate PASI and in 50 (44.6%) of milds. However, depending on the severity of the treatment, similar prevalence (40% in moderate and 46.8% in mild) was detected. No differences in the prevalence of MS according to sex (49% in men compared to 42% in women) were detected.

CONCLUSIONS: Although the literature demonstrates association between psoriasis and MS, in our centre statistically significant difference was not detected. The small sample size is one of the most significant limitations, so our results could be useful as a pilot study to propose a multicenter study.

Efficacy of two different behavioural intervention techniques on smoking cessation rates of patients who have been prescribed Varenicline; a randomized study

Sirin Parkan, Pinar Topsever, Efe Onganer

Acibadem University School of Medicine, Department of Family Medicine, Istanbul, Turkey

AIM: Identifying the most effective intervention for behaviour change in smoking cessation is still a matter of interest in scientific research. The research question is: Does informing patients about the mechanisms of developing nicotine addiction and the mode of action of the drug they are prescribed to quit smoking (varenicline) change the outcome of smoking cessation rates compared to patients who were prescribed varenicline and were subject to brief intervention about smoking cessation?

METHOD: Patients who presented to two periodic health examination outpatient clinics run by family physicians at a private hospital are eligible for this study. Inclusion criteria is smoking more than 10 cigarettes a day for the last consecutive year and giving informed consent. Exclusion criteria were diagnosis of mental disorders (e.g. depression, bipolar disorder). At outpatient clinic A the patients will be given brief intervention about smoking cessation and prescribed varenicline (control group). At outpatient clinic B patients will be prescribed varenicline and given additional information about the way nicotine dependence is developed and the mode of action of the drug they are prescribed to assist them quit smoking (varenicline) (intervention group). Patients will be assigned to intervention and control systematically by the receptionists of the hospital who give the appointments for the outpatient clinic visits. Primary outcome parameter will be smoking cessation rates of patients in both groups after six months. Sample size will be calculated to compute an estimated difference of smoking rates between two groups ($\alpha < 0,05$, $1-\beta$ 0,8, 95% CI). The estimated value will be extracted from the review of the recent relevant literature.

RESULTS: There are no results, yet. They will be ready at the conference' time.

Keywords: smoking cessation, preventional medicine, behavioral treatments

The Pattern of Physical Activity among Nurses in Labuan, Malaysia

Abdul Hafiz Mohamad Gani, Tijah Isa

Department of Health, Federal Territory of Labuan, Labuan, Malaysia

BACKGROUND: Nurses are healthcare individuals that often deal with patient's management including health education. Poor physical activity among the nurses may affect health status as well as willingness to promote healthy lifestyle.

AIM: The objective of this study is to assess the pattern of physical activity among the nurses and its associated factors.

METHODS: This was a cross sectional study conducted in Department of Health in Labuan, Malaysia. All registered nurses working with Ministry of Health (MOH) were given a set of self-administered questionnaires including their social demography, physical measurements and validated Malay version of the International Physical Activity Questionnaires (IPAQ). Pregnant nurses and male nurses were excluded from the study.

RESULTS: A total of 257 nurses answered the questionnaires out of 325 registered nurses in the MOH in Labuan giving a respond rate of 79%. In this study, 78.6% (n= 220) of the nurses in Labuan were physically active (Moderately Physical Activity 49% (n= 126) and High Physical Activity 29.6% (n=76). Factors that were associated with being physically active are normal Body Mass Index (BMI) and Waist Circumference (WC). There were no association between being physically active with participation in any exercise program and giving advice on exercise to patients.

CONCLUSION: About 78.6% of nurses in Labuan were physically active. It is recommended that health promotion should be targeted to those with high BMI and WC to improve their physical activity. However, all nurses are encouraged to participate in physical activity and give advice to patientson exercise regardless of their physical activity status.

Statins for primary prevention in people with a 10% 10 year cardiovascular risk: too much medicine?

Dharani Yerrakalva
University of Cambridge

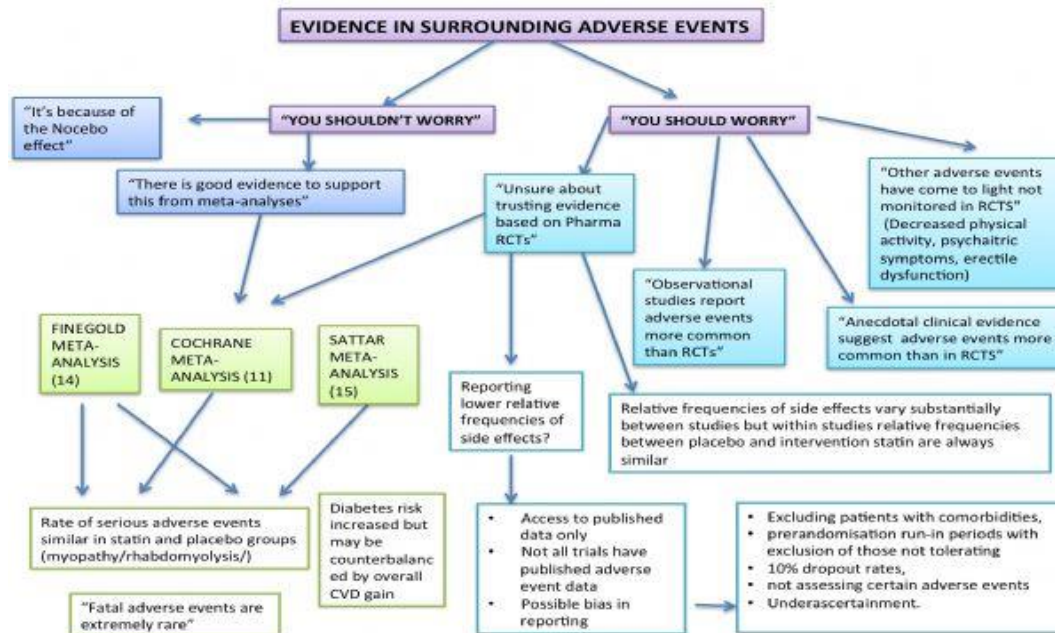

The recommendation from 2014 NICE guidelines on lipid modification to offer statins to people with over 10% risk of having a cardiovascular event within 10 years, a change from 20%, has deeply divided medical opinion. ‘Statin wars’, a public battle polarizing experts, has featured highly in media and journal coverage and is reflected in the widespread discontent of UK GPs. We analysed the factors which led to the health policy on statins in primary prevention, including two major meta-analyses which have been subject to the most criticism in this debate. We also layout the fall-out from the policy and what should be done going forward.

These two meta-analyses from the Cochrane and CTT groups found therapeutic benefit of a statin for primary prevention and suggest this outweighs the risks. However, we found there are serious and legitimate concerns over the available evidence raised by numerous professionals across disciplines. Though on balance, policy makers decided these concerns weren't enough to prevent the recommendatuon, without the backing of the medical community this recommendation has been rendered almost impotent. This may have damaged the future cause of statins, and it remains unclear how easy it will be to repair this.

Moving forward, there is a clear need for independent researchers to be allowed to analyse individual patient data and for release of adverse event data from the pharmaceutical RCTs. Only then might we be able to move towards a constructive resolution to what is set to be a drawn-out battle.

Keywords: Statins; primary prevention

Adverse Effects of Statins

Primary health care professionals views on the inclusion of the vaccine against human papillomavirus in the vaccine schedules. Across-sectional study

José Damián Garcés¹, Maria Reyes Oliver², Maria Victoria Bravo², Carmen Alvarez², Estela Lorenzo², Jesús Salvador Jiménez², Isabel Blasco¹, Leticia Muñoz², Laura Marqueta², Jose Miguel Seoane², Carmen Guillen², Concepcion Perez²

¹Centro de Salud "General Ricardos". Madrid. Spain

²Hospital Universitario 12 de Octubre. Madrid. Spain

Although the inclusion of the HPV vaccine has been registered in Spain since 2007, vaccination rates are lower than expected. The patients wish to be vaccinated is heavily influenced by information they have received from many source. The Knowledge of primary health care professionals affects the information provided to patients and is fundamental in the decision making. The aim of this study is to assess the opinions of primary health care professionals on the vaccine against HPV and their knowledge about HPV infection and its links to with cancer. A 19-item survey was drawn up. It included questions on basic aspects of HPV infection and marketed vaccines, personal opinion about the inclusion in the immunization schedules and their level of prescription and recommendation to their patients. From October 2013 to December 2013, 607 surveys were distributed among 20 primary health centers affiliated to the University Hospital 12 de Octubre. The results were analyzed using SPSS statistical package.

164 successfully completed surveys were obtained for analysis. 89% knew about the relationship between HPV infection and cervical cancer, 57.3% did not know any of the serotypes against which vaccines are targeted; 40.4% believed that there is insufficient data to support the commercialization of the vaccines. Of these, 65.7% argue that there is no data of its long-term effectiveness, 13.4% that there is no data as to its side effects, 13.4% believed that the cost effectiveness is not worthwhile.

There is a strong controversy among health professionals regarding the marketing and inclusion of HPV vaccine in immunization schedules. However, the knowledge of the primary care health professionals on key aspects of infection and vaccine protection are insufficient. The training of professionals in vaccination, cervical pathology and HPV infection should be improved to provide objective information on the use as this vaccine for patients.

Immunisation against flu at Health Centre Bijeljina

Srdjan Mijatovic, Zlatko Maksimovic, Aleksandra Mijatovic, Ruzica Jelusic, Dijana Dukic
Health Centre Bijeljina

Flu is an active, infectious, and very contagious disease caused by influenza virus.

The aim of the work is to show the significance of the vaccination against the seasonal flu for the time period from 2005 until 2014 in the territory of Bijeljina City.

A retrospective protocol analysis has been performed at Health Centre Bijeljina Hygiene-Epidemiology Unit. During the time period between 2005 and 2014, the seasonal flu vaccination was being continuously performed at Hygiene-Epidemiology Unit.

The greatest number of persons vaccinated is for 2008/2009 - 3,519 and 3,582 for 2009/10.

A gender based analysis has shown a higher percentage of male immunized persons. The greatest number of flu reported cases is for 2009/10 – 250 of them and 162 cases in the year of 2008/09. Data on the infected based on their gender has shown that flu often occurs in female persons, which can be linked with higher immunization percentage of men. The greatest number of the reported flu cases is for the age group from 10 to 19 years – 21.28 %, and the greatest number of flu reports is in February – 34.43%. During the past 10 years there was no flu epidemic in the territory of Bijeljina City. During the year of 2010 there were also 10 reported cases of H1N1 flu at Health Centre Bijeljina.

On the basis of the obtained results, 24,809 persons were immunized at Health Centre Bijeljina, which made an average of 2,408.9. The statistic data have shown that the youngest population categories are the most

affectable. 53% of the immunized were men and 47% were women. The results obtained have shown the significance of the flu immunization, because of a greater number of vaccinated male persons, and the smaller percentage of their presence among the reported cases.

AIM

The aim of the work is to show the significance of the vaccination against the seasonal flu for the time period from 2005 until 2014 in the territory of Bijeljina City.

METHODS

A retrospective protocol analysis has been performed at Bijeljina PHCC Hygiene-Epidemiology Unit.

During the time period between 2005 and 2014, the seasonal flu vaccination was being continuously performed at Bijeljina PHCC Hygiene-Epidemiology Unit.

The greatest number of persons vaccinated is for 2008/2009 - 3,519 and 3,582 for 2009/10.

RESULTS

A gender based analysis has shown a higher percentage of male immunized persons. The greatest number of flu reported cases is for 2009/10 - 250 of them and 162 cases in the year of 2008/09. Data on the infected based on their gender has shown that flu often occurs in female persons, which can be linked with higher immunization percentage of men. The greatest number of the reported flu cases is for the age group from 10 to 19 years - 220 (21.28 %), and the greatest number of flu reports is in February - 356 (34.43%). During the past 10 years there was no flu epidemic in the territory of Bijeljina City. During the year of 2010 there were also 10 reported cases of H1N1 flu at Bijeljina PHCC.

CONCLUSION

On the basis of the obtained results, 24,809 persons were immunized at Bijeljina PHCC, which made an average of 2,408.9. The statistic data have shown that the youngest population categories are the most affectable. 53% of the immunized were men and 47% were women. Analysis of the infected persons (i.e. number of the reported cases in the territory of Bijeljina City) has shown the figure of 1,034, out of which 550 women and 484 men. The results obtained have shown the significance of the flu immunization, because of a greater number of vaccinated male persons, and the smaller percentage of their presence among the reported cases.

Resveratrol - is it the perfect healthy life supplement?

Ines Abreu Mendes¹, Pedro Alves¹, Mileta Gomes², Ieda Paula³

¹USF D.SANCHO I, Aves Leiria, Portugal

²UCSP Almeirim, Aves Leiria, Portugal

³USF Cynthia, Aves Sintra, Portugal

Resveratrol (3, 5, 4'-trihydroxy-trans-stilbene) is a kind of polyphenol produced by the grapes and a few other plant species. Grape skins have 50-100 µg of resveratrol per gram. Rich natural sources of resveratrol include *Polygonum cuspidatum* (Japanese knotweed, 0,524 mg/g), red wines (0,1 – 14,3 mg/l), red grapes skins, berries such as blueberries, as well as chocolate, tea, peanuts and other nuts.

Resveratrol was attracting increased attention due to its diverse health benefits especially in case of cardiovascular diseases, cancer, diabetes, neurodegeneration and other age-related ailments.

Resveratrol was discovered to be a small molecule activator of sirtuin 1, an important molecular target regulating cellular energy metabolism and mitochondrial homeostasis. By the similar effects of resveratrol to the effects of exercise training, resveratrol was considered as an exercise mimetic.

In this poster review we present the latest advances regarding the availability, dosage, formulation, toxicity and the many effects of resveratrol in human and animal studies since 2000.

Due to resveratrol's many potential health applications, researchers tried to determine the optimal dose needed to capture its benefits. Studies showed that the optimal doses vary from 20 to 500mg a day. More clinical research on resveratrol were needed to determine the minimal effective dose, mode of delivery, frequency and safety/efficacy of doses for particular target populations.

Toxic data confirm that resveratrol was well tolerated and the adverse effects were moderate and reversible; nevertheless the efficacy and safety of resveratrol need to be further investigated.

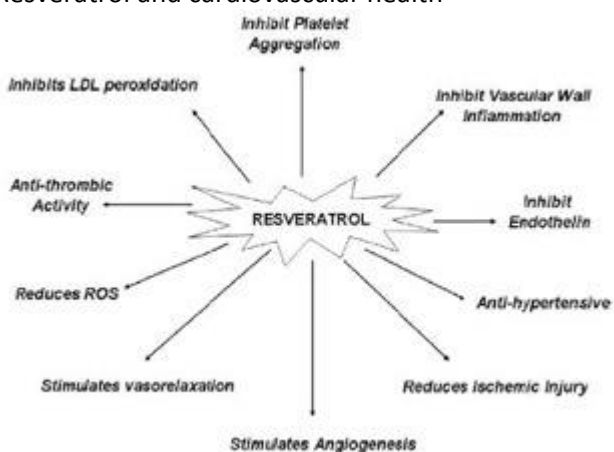

Keywords: resveratrol, clinical trials, metabolism, longevity

Isomers of resveratrol: chemical structures of trans and cis-resveratrol

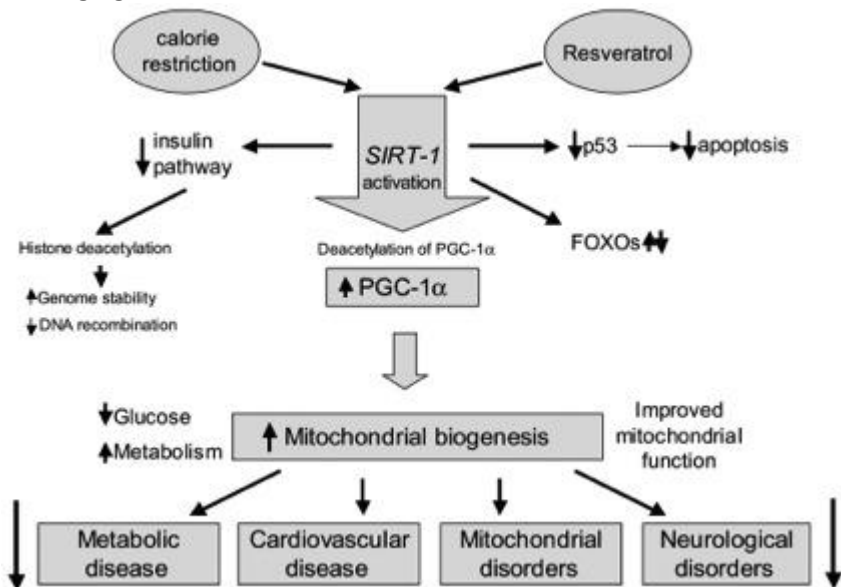

Molecule Resveratrol exists in two isoforms, trans-resveratrol and cis-resveratrol, the trans form, which is the preferred steric form in Nature, is relatively stable.

Resveratrol and cardiovascular health

Coronary heart disease (CHD), a primary cause of morbidity and death in developed countries, is regarded to be preventable through changes in lifestyle and diet. Epidemiological studies of a phenomenon commonly referred to as the French paradox show an inverse relationship between low-to-moderate consumption of red wine and the risk for CHD. One of the most well-known benefits of resveratrol is for cardiovascular health protecting against different cardiovascular diseases.

Anti-Aging Mechanisms of Caloric Restriction and Resveratrol

In numerous studies, restricting calorie intake in laboratory animals has been shown to prolong their life span by as much as 60%. In humans, consuming a low-calorie diet is associated with several possible markers of greater longevity, such as lower insulin levels and reduced body temperatures, along with less of the chromosomal damage that typically accompanies aging. People who consume a low-calorie diet may be less prone to diseases associated with being overweight or obese, such as metabolic syndrome, diabetes, atherosclerosis disease and cancer. Protein levels of SIRT-1 and PGC-1- α , both involved in calorie-restriction adaptation, were also increased, probably by activating AMP-activated protein Kinase in obese.

Major mechanisms involved in the anti-obesogenic effect of resveratrol

Several studies in the literature have addressed the potential anti-adipogenic effect of resveratrol under in vitro conditions. Many studies demonstrate that resveratrol shows anti-adipogenic effects at concentrations in the range of 20–100 μ M. This effect is observed in murine, porcine and human pre-adipocytes. There are marked differences among the reported studies in the treatment period length (24 h to 8 days), but in all cases resveratrol is able to inhibit adipogenesis. There is a good consensus concerning the mechanism of action underlying this effect. Thus, resveratrol inhibits C/EBP β , the early regulatory factor of adipogenesis. These changes can be

mediated by SIRT-1. ACC: Acetyl-CoA carboxylase; ACO: Acyl-CoA oxidase; BAT: Brown adipose tissue; C/EBP: CCAAT/enhancer-binding protein; CPT: Carnitine palmitoyltransferase; FASN: Fatty acid synthase; LPL: Lipoprotein lipase; PPAR: Peroxisome proliferator-activated receptor; UCP: Uncoupling protein; WAT: White adipose tissue.

Effectiveness of phone recruitment on pneumococcal vaccination

Francisca Rivera Casares, Rahalf Martin Pineda Coronel, Sebastián García De León Chocano, Silvia Pérez López, Silvana Serrano Montagud, Pilar Lorente Lorente
Centro de Salud Fuensanta (Valencia)

Background

The indication for pneumococcal vaccine (PNV) is complex due to:

- Collective to be vaccinated with very different characteristics
- Complex vaccination guidelines
- Irregular involvement of specialized level.

Aim

To assess the effectiveness of phone recruitment as a method to improve the coverage of PNV in immunocompromised patients in a Health Center

Method

- Identification of immunocompromised patients with PNV indication (hematological cancer, advanced nephropathy, or moderate nephropathy with diabetes or nephrotic syndrome, transplant, HIV disease, prolonged immunosuppressive therapy, and other) from electronic records
- Review of previous doses of PNV
- Phone recruitment of the patient by nursing
- Review immunization records of these patients one year after

Results

458 cases were included, 55% women, mean age 68.3 years. Prevalence was 4.5/100. 7.4% were hematologic cancers, chronic renal 60.3%, 4.1% transplant, HIV disease 19.9%, 14.2% had immunosuppressive drugs and 0.2% other causes.

One year after the intervention, the proportion of patients with 2 or more doses of PNV 23-valent increased from 4.5% to 5.5%, with one dose from 17.7% to 42.8%, and non-vaccinated declined from 77.7% to 51.7%. Patients vaccinated with PNV 13-valent were 52.6% (previously none). Additionally, the annual average of dose of influenza vaccine increased from 0.52 to 0.60 ($p < 0.0001$).

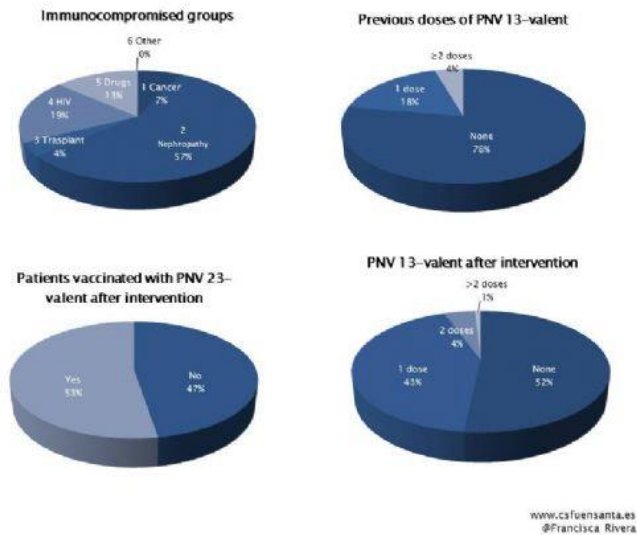

Conclusions

Phone recruitment for pneumococcal vaccination in adults is an acceptable and effective method.

The significance of early detection, diagnosis and treatment of asymptomatic primary hyperparathyroidism in primary health care

Aleksandra Petar Jesic, Aleksandra Kosojevic, Ljiljana Jandric

Department of Family Medicine, Primary Health Care Centre Novi Beograd, Serbia

Primary hyperparathyroidism occurs as a result of increased and uncontrolled secretion of parathyroid hormone due to hyper function of one or more parathyroid glands, becoming the third most common endocrine disease with the highest incidence among women in the postmenopausal period with a prevalence of 21 / 1000 women aged between 55 and 75.

The patient (1953) comes to family doctor complaining of leg muscle and LS spine pain, constant fatigue, sleepiness, and occasional bloating and nausea.

Data from health records show that patient has been treated and undergone checkups for primary hypertension and acute gastritis.

Laboratory analysis:

Alkaline phosphates 51 U/L (100-290 U /L)

The Effect of Education on Anxiety Levels of Parents of Children with Serebral Palsi: A Randomized Controlled Study

Emine Hilal Seydel, Hülya Yıkılkan, Derya İren Akbıyık, Cenk Aypak, Süleyman Görpelioğlu

Department of Family Medicine, Dışkapı Yıldırım Beyazıt Training and Research Hospital, Ankara, Turkey

Most of the disabled and their relatives aren't able to take advantage of offered services and the rights given to the disabled. Stress and the anxiety levels were found high among the relatives of disabled. In our research, we aimed to investigate the families of the children with cerebral palsy (CP) living in Ankara, for the knowledge and satisfaction level about their legal and social rights and also the effect of education programme on their anxiety level.

Eighty eight parents of children from two different special training and rehabilitation centers having CP were included into our research. Their anxiety level was evaluated by State-Trait Anxiety Inventory (STAI). Randomly selected intervention group was given the education programme which included the disabled rights. After six weeks, both groups were re-taken the STAI. The change on anxiety levels of both groups were evaluated. At the end of the study, control group also took the same education.

Randomly selected 50 parents were the intervention group and 38 the control group. In terms of the services given to the disabled, 79.5% of the parents were not satisfied. When the knowledge, satisfaction level and the recommendations about education, health, rehabilitation, vocational education, employment and social aid were asked, it was clear that the services and the regulations were insufficient. Anxiety levels of both groups were high. There was a meaningful decrease in their anxiety level in the intervention group after six weeks. There was no change in the anxiety level of the control group.

The disabled rights and services given to the disabled are insufficient. They should be regulated according to the needs of the disabled and their relatives. Education programme was shown to decrease the anxiety level in our study. Education programmes in different fields aiming the needs of the relatives of disabled are recommended.

Evaluation of Colorectal Cancer Related Knowledge, Attitudes and Behaviours and Compliance to Occult Blood Test Among Individuals Over 50 Years Old

Sinem Aslan Karaoglu, Dilek Evcik Toprak

Şişli Hamidiye Etfal Eğitim Araştırma Hastanesi Aile Hekimliği Kliniği

The aim of the present study was to evaluate of the level of knowledge about colorectal cancer (CRC), factors those can be related with CRC and the compliance to the fecal occult blood test (FOBT) which is used for screening purposes in our country in individuals aged over 50 years old. A total of 283 patients between the ages of 50-75 years who applied to Sisli Hamidiye Etfal Hospital Family Medicine outpatient clinic with any reason between February 2014-October 2014 were included the study. Sociodemographic informations, knowledge, attitudes and behaviors related CRC and its screening were questioned. After mentioning the standard training brochures about CRC, we answered their questions related with this subject. The importance of FOBT was emphasized. The compliance of patients were evaluated by following whether they gave the FOBT. The average level of total knowledge score about CRC was 6.9 ± 2.6 . Although our advise screening with FOBT 60.4% (n=171) of participants did not had FOBT. Nearly %69,6 (n=39) of the participants who had family history of CRC, did not accept to have FOBT even though our recommends and specifying that they are risky. 11 (3.8%) of the participants made FOBT for three-tier as described. There were 10 people (3.5%) who were positive. One person who was positive and underwent a colonoscopy was diagnosed as CRC. There were 5 (1.8%) people who got bowel cancer-related information from their family physicians, and there were 6 people (2.1%) who got bowel cancer screening recommendations from their family physicians. Thus, the participants do not have enough knowledge about symptoms, risk factors, screening of CRC and CRC screening were recommended and performed with very low rate in primary care. Raising the awareness of people about CRC and its screening, especially with television and internet which are most followed media; better integration of family physicians in currently existing scan program of CRC and disseminating of the scanning program will increase the chance of prevention, early diagnosis and treatment.

Evolution of flu vaccine coverage in pregnant women (2010-2014) in Valencian Community Spain

Jose Antonio Lluch Rodrigo¹, Ana María Alguacil Ramos², Rosa Martín Ivorra¹, Antonio Portero Alonso¹, Eliseo Pastor Villalba¹

¹Servicio de Salud Infantil y de la Mujer. Dirección General de Salud Pública. Valencia Spain

²Universidad Católica de Valencia San Vicente Mártir, Valencia Spain

Background and aim

Vaccination of pregnant women against influenza has been recommended since the 90s justified by increased hospitalizations when influenza affect pregnant women and also the possibility to protect the newborn against influenza by transfer of antibodies.

Following the 2009 influenza pandemic pregnancy was considered one of the groups at risk of complications from infection with influenza virus and vaccination is recommended in any trimester of pregnancy, given the absence of risks vaccination

In the Valencian Community health authorities offer free vaccination to all pregnant during the annual vaccination campaign against influenza in primary care centers

The aim of this study is to review the evolution of flu vaccine coverage in pregnant women in the last five seasons.

Method

The number of pregnant women vaccinated against influenza has been obtained from the data recorded in the system of vaccine information CV

The denominators were estimated from the data of births registered in the National Statistics Institute of Spain It has been estimated coverage (%) and confidence intervals at 95% for each of the study season.

Results

During the study period there have been a total of 236,197 births, and is estimating that 177,149 pregnancies have coincided with the vaccination period (October to December each year).

A total of 20163 pregnant women (11.38% coverage –CI95% ± 0.15-) were vaccinated. Seasonal coverage (CI95%) were 8.63 (± 0.28); 7.66 (± 0.27); 9.23 (± 0.30); 14.71 (± 0.38) and 17.88 (± 0.42) for each of the seasons from 2010-11 through 2014-15.

Conclusions.

Vaccination coverage against influenza in pregnancy remains very low despite the progressive increase that has been occurring since 2010

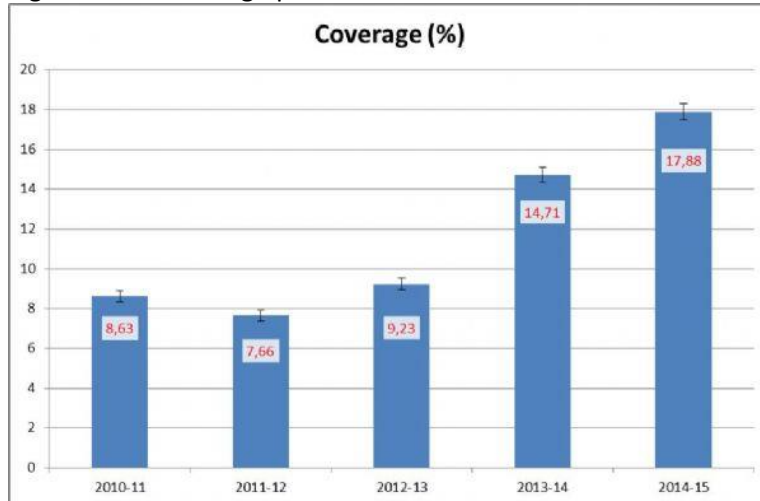

Specific strategies are needed to improve this coverage.

Pertussis vaccination pregnant women strategy in Valencian Community. Spain

Ana Maria Alguacil Ramos¹, Antonio Portero Alonso², Rosa Martín Ivorra², Eliseo Pastor Villalba², [José Antonio Lluçh Rodrigo](#)²

¹Universidad Católica de Valencia San Vicente Mártir. Valencia. Spain

²Servicio de Salud Infantil y de la Mujer. Dirección General de Salud Pública. Valencia. Spain

Background & Aim

The incidence of pertussis in Valencian Community (VC) has increased during last years. During the first 44 weeks of 2014 there were 500 cases; 60 of them were children aged less than 3 months (523 cases per 105; 81,7 % hospitalized; 3 died).

Since 1st January 2015 free dTpa vaccination is offered to pregnant women in their 27th through 36th week of pregnancy. It is recommended one dose of dTpa vaccine during each of the pregnancies. All immunizations may be registered in the Vaccination Information System (SIV)

VC Health Authorities hope to vaccinate around 27.000 women during the first year (60 % coverage).

It has been done pertussis vaccination scientific information by consensus with scientific and professional associations. It has also been make meetings with health professional and diffusion activities (including fact sheet).

The aim of this study is to present the preliminary results (coverage) of the programme.

Method

A descriptive retrospective study of pregnant women vaccinated against pertussis has been done. The coverage has been estimated using as denominator the new-borns during February and March 2015. We analyse the week of pregnancy in which they were vaccinated.

Information sources: SIV and the new-born screening registry.

Results

6,406 women were vaccinated during January and February 2015, while the estimated pregnancies were 7,117. The coverage value was 90.01 % (95%CI: 89.31-90.71). 90 % (95%CI: 89.45-90.91) of women have received the vaccine in the recommended gestational period, 1.64 % (95%CI:1.32-1.95) were vaccinated early and 8.18 % (95%CI: 7.51-8.85)after 36th week.

During the study period the Epidemiological Surveillance System has not detected any case of pertussis in young children.

Conclusions

Coverage results show excellent acceptance of vaccination, related both the importance of the problem as the developed actions. It seems that the effectiveness of the strategy will be very high.

Patients with type 2 diabetes (MD) care in general practitioner practice

Mindaugas Paulius¹, Indrė Baužienė¹, Indrė Ličytė¹, Kazys Simanauskas¹, Eglė Simanauskienė²

¹Faculty of Medicine, Vilnius University, Lithuania

²Children’s Hospital, Affiliate of Vilnius University Hospital Santariskiu Klinikos

Objective. Increasing life expectancy, changing dietary habits and physical activity decreases the family doctor is a very urgent problem of type 2 diabetes care. The aim - to evaluate patients with type 2 diabetes, a family physician supervision practice.

Materials and Methods. Onetime retrospective study was carried out, which was assessed in patients with type 2 diabetes care in 2013-2014 year (how much was carried out laboratory tests and how they were treated). A statistical analysis was done and the significance assessed by a X-square test. The statistical difference was considered spreads across if the p value was below 0.05.

Results. HbA1c has never been studied in 13% of all patients, 15% of all carried out every 3 months, and the majority of studied this indicator has been studied less frequently. HbA1c ≤7 percent were for the majority of all patients. Creatinine concentration has not been studied more than once a year up to 50%. Urea rated even lower proportion of patients. Half of the patients have not been studied lipids, only for three patients these parameters were in line with the objectives of the control of diabetes. According to treatment - oral (tablets) drugs accounted for 36 cases, insulin – 4, combination therapy (insulin and tablets) – for 6 patients.

Conclusions. Type 2 diabetes control in treatment should be carried out more actively in Vilnius University Hospital Santariškių Clinic’s Family Medicine Center. Glycosylated hemoglobin, lipids and renal function control is inadequate.

⁵Department of Family medicine, Konkuk University Medical Center, Konkuk University College of Medicine, Seoul, Korea

⁶Department of Family medicine, Ilsan Paik Hospital,, Inje University College of Medicine, Ilsan, Korea

BACKGROUND: This study proposes to investigate the relationship between depression and lifestyle associated with health.

METHODS: Cross-sectional data from a total of 509 couples from primary care participants over forty years old in 2009-2011 were analyzed for this study. Depressive symptoms were defined as ≥ 25 points on the Center for Epidemiological Studies – Depression (CES-D) scale. A data of smoking, drinking, exercise, regular diet and breakfast intake was collected with self-administered questionnaire.

RESULTS: Participants have a depressive symptoms was 92(9.6%) persons in the 1018 samples. In the multivariate analysis, low income(OR 3.74, 95%CI 1.84-7.60), risky drinking(OR 2.23, 95%CI 1.12-4.41), few breakfast intake(OR 1.83, 95%CI 1.07-3.11) were associated with depression($p < 0.05$). But obesity was associated with 48.3% reduction in depression(OR 0.51, 95%CI 0.29-0.91, $P = 0.022$). Irregular diet, smoking, exercise were not associated with depression.

CONCLUSIONS: Risky drinking and few breakfast intake were significantly increased in participants with depression in primary care.

Women's Weight Loss Strategies In The Demographic, Social And Psycho-Emotional ContextVioleta Ozeraitiene¹, Daiva Makaraviciene², Sonata Varvuolyte³¹Department of Nursing and Fundamentals of Internal Medicine, Vilnius University, Lithuania²Department of Antakalnis Outpatient, GP Center, Vilnius, Lithuania³Baltupiai Family Medical Center, Vilnius, Lithuania

BACKGROUND: About 25-30% of normal weight women are reported to have tried to lose weight. We speculate that social pressure to be thin and women's psycho-emotional stress status could influence the weight loss strategies.

AIM: To assess the relationship between women's weight loss strategies and their psycho-emotional state, social and demographic factors.

Materials and methods. 120 females (average age 28.7±9.9) were interviewed in Vilnius Outpatient Center using a structured questionnaire and Reeder stress inventory scale (Chapman, & Coulson, 1968). Anthropometric parameters were evaluated too.

Results. Women were divided into: 1st group (≤30 years old; n=84; 70%) and 2nd group (>30 years old; n=36; 30%). 33 (27.5%) females had central obesity. 95 (79.2%) subjects were physically active on a daily basis, two-thirds of their sports activities lasted from 30 to 60 minutes. Only 29 (24.2%) of them did not experience stress. There was no significant difference ($p>0.05$) between the age and stress state. Young women constantly tended to be more physically active, chose different types of activities (aerobic, muscle stretch exercises, etc.) more than older ones. Older women were less physically active, their dieting lasted longer, with more trust in doctors and dietitians, however, they were also more prone to weight loss experiments. We found a statistically significant relationship between experienced stress level and weight/hip circumference, and body mass index (BMI).

Nutrition had a significant impact on the effectiveness of weight loss ($p < 0.05$).

Conclusions. Greater psycho-emotional stress is experienced by women with increased circumference of hips, BMI and weight. There is no significant difference between education level and weight loss strategies, between the age and stress state. Young women are more physical active, while older women are more prone to various experiments with weight loss and dieting. Nutrition had a significant impact on the effectiveness of weight loss too.

Tele-Care System of Body Temperature Monitor for Prevention of Dengue Fever in a Kindergarten

Chen Cheng Yang¹, Chen Cheng Yang², Chen Cheng Yang³, Chen Cheng Yang⁴, Chao Hung Kuo³, Chao Hung Kuo⁵

¹Community Health Promotion Center, Kaohsiung Municipal Cijin Hospital

²Department of Family Medicine, Kaohsiung Municipal Cijin Hospital

³Department of Internal Medicine, Kaohsiung Municipal Cijin Hospital

⁴Department of Family Medicine, Kaohsiung Medical University Hospital

⁵Department of Internal Medicine, Kaohsiung Medical University Hospital

Background and Aim

Dengue fever is an important issue in tropical medicine, which was broadly influenced in Cijin, Kaohsiung City, southern Taiwan. In 2014 summer, a huge outbreak of dengue fever was happened, which had affected more than 15000 cases according to Center for Disease Control, Taiwan. Children are easily influenced group, especially during school years. In school, a screening tool to checking the body temperature, a sign of dengue fever, become a convenient methods for care givers to notice the sick subjects. Our purpose is to investigate whether a tele-care system of body temperature measurement is effective to preventing dengue fever in kindergarten.

Methods

Twenty six children were recruited to our study after collection of informed consents of their parents. Body temperature was measured during weekdays by the tele-care system. The system consists of a clinical thermometer and a box for dealing with data. The data were sent to call center, where nurse can make real-time reaction to their teacher.

Results

During the intervention, no fever subjects were found, neither dengue fever was diagnosed. The average measurement number was 17.77 times in the 26 children. The average body temperature was 36.25°C, the maximum was 37.0°C while the minimum was 34.6°C. The missing data was because the participants were off during the weekdays. However, we phone children with missing data to make sure no one was influenced by dengue fever.

Conclusion

Cijin district is a sandbank belonged to Kaohsiung city, the initiation place where western medicine in Taiwan, advocated by Doctor Yage Ma in 1865. Nowadays, we started a new tele-care system for disease prevention in children. In conclusion, the system is successful in dengue fever prevention. We will continue promote the new technology for community health in the future.

Physical activity and smoking behaviors among medical students of a Middle Eastern country

Lana El Osta¹, Nada El Osta¹, Badi El Osta²

¹Department of Public Health, School of Medicine, Saint-Joseph University, Beirut, Lebanon

²Georgia Regents University Cancer Center, Augusta, GA, USA

BACKGROUND AND AIM: Moderate physical exercises and non-smoking behaviors are relevant approaches to reduce the risk of cardiovascular diseases and malignancies, which are currently the major human health problems. And physicians are well positioned to provide physical activity and tobacco cessation counseling to patients. There is convincing evidence that clinical providers who themselves act on the advice they give provide better counseling and motivation of their patients to adopt such health advice.

The aim of this study was to determine the level of physical activity, tobacco smoking and alcohol consumption among Lebanese medical students, future health promoters.

METHODS: An observational cross-sectional survey using an anonymous structured self-administered questionnaire was conducted among 579 medical students (year I to internship program) at a major Lebanese school of medicine. Tobacco/alcohol consumers were defined as students who reported a daily use of tobacco and/or alcohol within the past year.

RESULTS: A total of 505 participants responded to the survey (response rate: 87.2%). The prevalence of tobacco use was 11.9%, and regular alcohol consumption was 5.3%. It was significantly higher among men and older students ($-p\text{-value}<0.0001$). More than half (58.7%) of the participants exercised once per week and more: male significantly more than women, younger students more than others ($-p\text{-value}<0.0001$). However, 15.9% of all participants rated themselves as physically inactive, mainly because of lack of time and energy. The majority (81%) of the students were aware of the importance that non-smoking status and adequate levels of physical activity confer on health.

CONCLUSION: Fortunately, our study revealed that our medical students, future health promoters, act on the advice they must provide. These results may have important implications for future studies evaluating the rate and quality of physical activity and smoking cessation counseling delivered by physicians.

Smoking as a risk factor for COPD

Amra Lasic, Neda Ferizovic, Elma Merdzanovic, Rasema Sehovic, Zlata Frasto, Dzenisa Ibisevic
Public Health Centre of Sarajevo Canton, Bosnia and Herzegovina

INTRODUCTION: The WHO estimates that 1.1 billion people worldwide smoke and that will increase to 1.6 billion by 2025. In underdeveloped and developing countries, COPD rates are growing alarmingly.

AIM: To investigate the effect of smoking on lung function of middle aged and younger patients without prior history of lung disease.

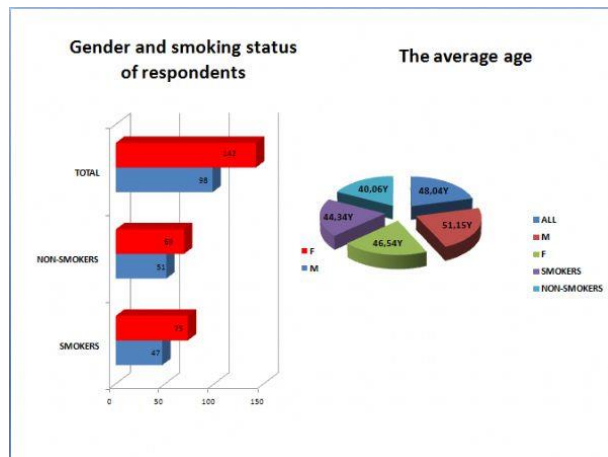

METHOD: Epidemiological research, done in 3 municipalities of Canton Sarajevo (September – December,2014) on 240 test subjects (120 smokers,120 non-smokers), age range 35 – 65. Smokers were divided into 3 subgroups based on the length of time they are smoke and the number of cigarettes smoked per day (up to 15Y, 16 – 35Y,over 35Y,up to 20 c/d, 21 – 40 c/d, over 40 c/d). Researching parameters: age, sex, smoking history, pulmonary function and the age of lungs measured with mini-spirometer (copd-6).

RESULTS: Of 240 patients, the average age of 48.04, SD 17.67., 142 women (73 -51.4% smokers) 98 men(47 - 47.9% smokers). All smokers smoke cigarettes on average 23.5 years 24.5 cigarettes/day. 40% of them smoke >15 years,> 21 cigarettes/day. 7.5% smoke >35 years, >30 cigarettes/day. 46.6% of smokers and 10.8% of non-smokers have index 1 obstruction (50% <FEV₁ <80%). According to the GOLD guidelines (FEV₁ / FEV₆ <0.73 and 50% <FEV₁ <80%) GOLD stage 2 COPD have 16 or 13.3% (10M6F) smokers (all smoking >15 years >21 cigarettes / day) and 1 (M) non-smoker. The average age of the lungs of smokers is 25 years higher than their average age while with non-smokers 9 years.

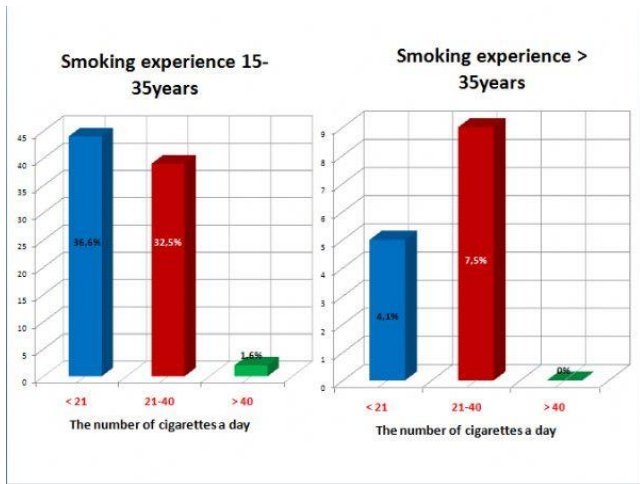

CONCLUSION: A significant difference in the measured Index 1 obstruction - 46% of smokers, while 10% of non-smokers, revealed 13,3% of COPD in smokers while 0.83% in non-smokers, as well as the higher age of the lungs of smokers, confirms the direct effect of smoking on lung function.

Hepatocellular Cancer Case: Newly Diagnosed in a University Hospital Check-up Polyclinic

Fisun Sözen, Sinem Aydemir, Yasemin Çetinel, M. Gökhan Eminsoy
Department of Family Medicine, Baskent University, Ankara, Turkey

INTRODUCTION: Everyday many people go health checks even if they are healthy. Some thoughts, it may cause unnecessary diagnoses and tests which enhances the health anxiety. But most views agree that routine health checks lead to early diagnosis of the diseases and cost effective treatments. Hepatocellular carcinoma (HCC) is the fifth most common cancer in men and eighth most common cancer in women worldwide, resulting in at least 500.000 deaths per year. So, early diagnosis and treatment of HCC is important. We report a HCC case who admitted to the check-up polyclinic for his annual health check and having no symptoms.

CASE: A 75 year old man admitted to a check-up polyclinic for his annual health check-up. He had no complaints related to his health and declared that his last annual health check-up results were in normal limits. His past medical history revealed no chronic illness, no surgery, no allergies and no medications. He smoked 37.5 packages/year and drank 3-4 glass of raki/day. Family history; skin cancer, lung cancer. In his physical examination there were no significant abnormal findings. We performed blood tests, chest x-ray, echocardiography and all abdominal ultrasound. His laboratory tests revealed no any abnormal results except CRP, GGT, alkaline phosphatase high levels. In his chest x-ray there were multiple nodules, the echocardiography was normal, in the all abdominal ultrasound report; liver was in normal sizes, parenchymal echogenicity was normal; there was a hemangioma which required further evaluation. After clinical, laboratory and radiodiagnostic evaluation we thought that there could be a malignancy in his body. Then we oriented him to the other departments of our hospital. He got the HCC diagnosed and started to the treatment.

CONCLUSION: Worldwide the spread of the cancer cases are increased and it is important to diagnose the disease and started the treatment in asymptomatic period by the interpretation of detailed history, physical examination, blood and screening tests. With this case we emphasize that check-ups have an important role in early diagnose and treatment of the diseases.

The Diabetes Care Pathway in the General Practice in a Primary Care-Trust (Pct) In Rome

Anna Chiara Bianco¹, Eleonora Leoni², Gabriele Baccifava³

¹A.C. Bianco, Junior Doctor Trainee 2011-2014, ASLRME 5° Area, Lazio, Italy

²E. Leoni, Junior Doctor Trainee 2012-2015, ASLRME 5°Area, Lazio, Italy

³G. Baccifava, General Practitioner, ASLRME, Lazio, Italy

The diabetes care pathway (PDTA) consists in a cost effective care planning and management, used to improve medical assistance and to prevent short and long-term complications for patients.

Data were obtained from a General Practitioner (GP) database in the primary care trust (PCT- ASLRME) in Rome and recorded in a specific excel file. Diabetic patients were selected. The registered variables were: age, diabetes' management (start date of PDTA, successive specialist visit, duration of the disease), review of metabolic control (HbA1C, and blood glucose monitoring, therapy assessment), review of complications (diabetic retinopathy, microvascular complications, diabetic renal disease, diabetic neuropathy, cardiovascular risk factors, hyperlipidaemia, hypertension, feet problems, erectile dysfunction), the need of care manager support, and the patients' compliance values.

The patients involved were 74: the 96% of them were adherent to suggested diagnostic and therapeutic pathway. The non-adherent 4% was identified by GP through the "case finding" and quickly visited in the diabetic centre. Using standardized database of "PDTA", the GP can easily identified the non-target patients and improve the management of their disease. The PDTA makes connections between GP and specialist practitioners using diagnostic, therapeutic and educational established standard.

In conclusion our study suggests PDTA plays an important role in the management of chronic disease, leading to an improvement of quality of life, reduction of hospitalization and patients' satisfaction and compliance.

Food and “Meds” – what a confusion

Maria Miguel Sá¹, Ana Margarida Pinho¹, Juliana Pais²

¹USF Famílias, ACeS Entre Douro e Vouga, Santa Maria da Feira, Portugal

²USF Cuidar, ACeS Entre Douro e Vouga, Santa Maria da Feira, Portugal

Background & Aim

Food is considered to be an important part of any and every culture around the world. What we eat, the quantity of food and the number of meals may bring several consequences to the health of each individual.

The existence of food-drug interaction is well known about, but many times forgotten both by physicians and patients. This interaction deserves especial attention especially if the results the certain treatments are called into question.

The purpose is to raise awareness for the importance of the drug-food interaction being that it represents a point of treatment failure, especially in Primary Care.

Method

Article search in several evidence-based medical databases using MeSH terms.

Results

Food-drug interactions can alter the purpose or the toxicity of one or both substances. These interactions can occur at several levels such as: absorption, pharmacodynamics, metabolism or renal elimination.

The absorption is the fase where most of this interaction occurs.

The pharmacodynamics demonstrate the relationship made between two compounds and it’s effect can be augmented (synergism), antagonized or can suffer enzymatic effects.

Alterations in the metabolism are another important point of this analysis because most drugs are metabolized in the liver, influenced by cytochromes which can also be affected by several foods.

The last point where this interaction can occur is at the renal elimination. These compounds can acidify the urine (which promotes a faster elimination of some drugs) or it can raise the pH level of urine facilitating the elimination of drugs with acidic proprieties (such as penicillin or warfarin).

Conclusions

A healthy and proper doctor-patient relationship makes it easier to approach these issues and to answer the questions made by the patients.

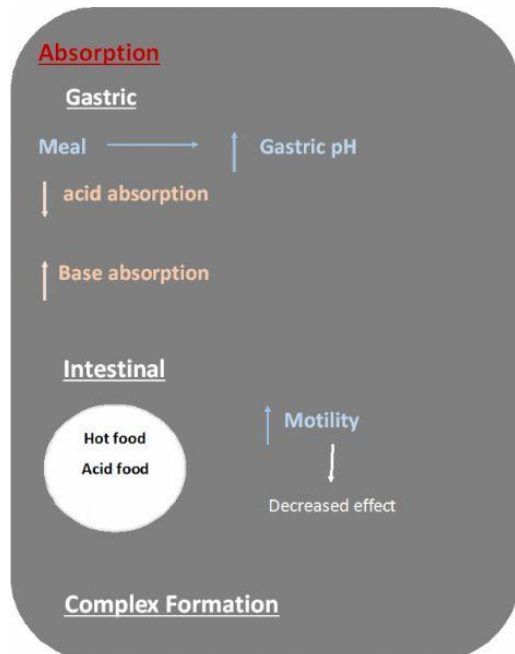

The family physician is a fundamental pillar when approaching this topic because of their especial relationship with their patients.

Structure of Public Health Nursing Work in Croatia: a Longitudinal Study 1996-2012

Dobrislav Šimić¹, Zvonimir Bendeković²

¹Family Practice »Dr. Dobrislav Šimić«, Bednja, Croatia

²Health Centre of the Varaždin County, Family Practice Lepoglava, Lepoglava, Croatia

Background & Aims

In Croatia, public health nurses (PHNs) have been members of family doctor (FD) teams for decades, performing a multifunctional and polyvalent scope of activities for the inhabitants of a catchment area. The number of visits to post-partum women, new-born babies, babies and small children are very well defined by the protocol, while the visits to other groups are not defined. The main aim of the study was to investigate the trends in the number and structure of PHN visits in the period from 1996 to 2012.

Methods

The data were obtained from Croatian Health Service Yearbooks. Data on the total number of visits and visits to the target population groups were collected for each year. The number of performed visits (visits “paid”) was compared to the number of visits prescribed by the protocol („estimated number of visits”).

Results

The obtained results indicate that the average number of visits per one PHN is relatively high, annually ranging between 1380.3 and 1826.5 visits, or between 5.5 and 7.3 visits daily. The structure of visits indicates that the visits fall out of the scope of PHN work, considering that prevention should be the main goal of public health nursing. More than 50% of visits involve visits to chronic patients. Drawing a comparison between the number of performed and estimated visits to women and children, it was found that visits to post-partum women and newborn babies were overrepresented, while visits to pregnant women and small children underrepresented.

Conclusions

The results strongly indicate that PHNs are overloaded by the number of visits, especially to chronic patients and mothers and new-born children. Bearing in mind different working conditions and differences in population needs, it will be worthwhile to reconsider the standards of PHN service.

Evaluation of The Relationship Between Sociodemographic Characteristics and Night Shifts with Smoking Habit Among Sisli Hamidiye Etfal Training and Research Hospital Nurses Who Smoke

Serap Nizam, Dilek Toprak, Merve Müge Üçüncü

Department of Family Medicine, Sisli Hamidiye Etfal Training and Research Hospital, Istanbul, Turkey

AIM: Health staff is a profession group those should be role model for healthy life style to the community. In this study, we aimed to identify the relationship between sociodemographic characteristics and night shifts with smoking habit in Sisli Hamidiye Etfal Training and Research Hospital (SHETRH) nurses who smoke.

MATERIAL-METHODS: This study is a descriptive-analytic research. Data were collected in SHETRH staff nurses who smoke. A questionnaire included sociodemographic characteristics, working and night shift conditions, smoking habit features and Fagerstrom Nicotine Dependens Test (FNDT) were performed to the subjects. In SPSS17.0 program frequency, t test, and Chi-square were used for data analyzis.

RESULTS: 78% of subjects who participated in our study were women, 22% were male and the average age was $29,47 \pm 6.44$. While 18% were working in intensive care unit, 25% were staff in emergency service. 44% were married, and 74% had no child. Regarding the FNDT 70% of them identified as "medium/low level dependency",

30% as “high/very high dependency”. There was no significant relationship between the nicotine dependence and age, gender, marital status, number of children, income level, the presence of chronic disease, working duration and mother/father's cigarette use ($p > 0,05$). It was observed that as the education level increased, the age to start smoking were also increased ($p = 0.027$). The average age to start smoking was 18.52 ± 4.99 and 57% had started smoking before 18 years. Also nicotine dependency scores were significantly higher in this group than those who started smoking after the age of 18 ($p = 0.000$).

Weekend or weekday shifts were not related with the nicotine dependency scores and amount of daily smoking ($p > 0.05$).

Despite higher dependency scores, working in intensive units wasn't a significant factor ($p = 0.076$).

CONCLUSION: No relationship was observed between smoking habit and night shift number. Smoking health workers have to receive information and extra support for smoking cessation; by this way, they would be role model to the community.

Doctor, what about my thyroid?

Juliana Pais¹, Maria Miguel Sá², Ana Margarida Pinho²

¹USF Cuidar, ACeS Entre Douro e Vouga, Santa Maria da Feira, Portugal

²USF Famílias, ACeS Entre Douro e Vouga, Santa Maria da Feira, Portugal

BACKGROUND & AIM:

The thyroid pathology is one of the most common pathologies in the spectrum of the endocrine diseases. The disseminated use of ultrasonographic techniques serves as a first-line diagnosis of the thyroid nodular pathology. As general practitioners (GP) we are on a daily basis confronted with the patients' pressure to perform complementary exams, due to the fear of neoplasia.

The objective is to alert to the importance of this matter at the Primary Health Care (PHC). Review this subject after the emergence of a portuguese guideline from 2014, once this is frequently motive of consultation at the PHC.

METHOD:

Article research on the evidence-based medicine databases without date limitations using the MeSH terms.

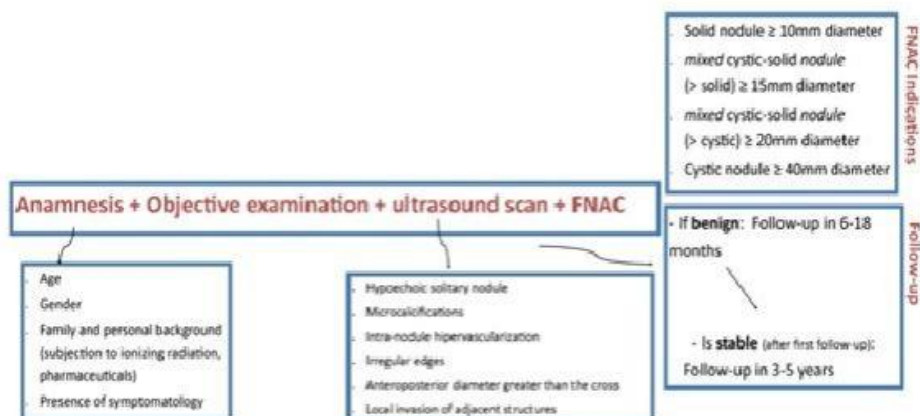

RESULTS:

The first approach to the thyroid pathology must consider its influencing factors, like age, gender, family and personal background, subjection to ionizing radiation, pharmaceuticals which interfere in the thyroid function and presence of symptomatology. The next step must be the objective examination, particularly the palpation of the thyroid and the cervical ganglion chains and then an analytical assessment of the thyroid function. The ultrasound scan serves, specially, to characterize the nodular pathology, as well as to assess the need of a fine-needle aspiration cytology (FNCA), while this last technique permits the diagnosis of malignancy.

CONCLUSIONS:

The monitoring of and decision to perform a FNAC must be done considering the patient's particular risk factors, as well as the presence of the symptomatology, changes revealed on the objective examination and the nodule's characteristics on the ultrasound scan assessment. As GP we must create a relationship with the patient that permits us to communicate and explain the relative neoplasia risk associated to the thyroid nodule, avoiding unnecessary exams and procedures and the anxiety related to the fear of cancer.

Quality of Life of Patients After Acute Coronary Syndrome

Didem Kafadar¹, Fatma Gonul Dogan¹, Nüket Bayram Kayar¹, Muhammet Çömçe¹, Hasan Ayberk Çakırlar¹, Abdurrahman Polat¹, Burak Ayça², Mustafa Hakan Dinçkal²

¹Department of Family Medicine, Bagcilar Training and Research Hospital, Istanbul, Turkey

²Department of Cardiology, Bagcilar Training and Research Hospital, Istanbul, Turkey

Background & AIM: As treatments for chronic diseases have evolved, quality of life of patients has drawn attention. Cardiovascular diseases(CVD) have become a public health problem as they affect the quality of life(QoL) of patients. QoL is subjective and there are different aspects that define it. Short Form-36 Health Survey(SF-36), developed by Ware et al, represents eight health concepts. It has been widely used for both general population and different patient groups.

METHODS: The study was conducted with the patients admitted to cardiology and family medicine outpatient clinics who have had a history of hospitalization for ACS. Patient inclusion criteria were a history of angiography proved ACS. Sociodemographic features and laboratory values of the patients at the time of the survey procedure were recorded. To assess the health related quality of life of the patients SF-36 was used.

RESULTS: A total of 100 patients, 77(77%) men and 23 (23%)women completed the study. The mean age of the group was 60.38. 50% of patients were 60 or older. Different domains of the survey were compared. There were significant differences between physical functioning(PF), role limitation due to physical problems, bodily pain, mental health and general perception of health mean scores of men and women($p=0.001$, $p=0.036$, $p=0.001$, $p=0.048$, $p=0.019$ respectively). PF scores of patients under 60 years were significantly more than patients over 60($p<0.001$). Scores of social function(SF) were the highest among all domains in both men and women patients. **CONCLUSION:** SF domain being the highest score may be explained as Turkish family structure and strong relationships among patients' relatives. Men had higher scores for all domains revealing that QoL of women have been affected more. Chronic diseases have larger effect on QoL of women patients than men. SF-36 may be utilized by family physicians for biopsychosocial approaches towards patients with a ACS history.

The importance of stretching: Prevention of muscular injury in medical office

Carolina Martins Moreira¹, Pedro Pinho Caetano², Carlos Matos¹, Raquel Correia¹, Luis Afonso Vouga¹, Pedro Cantista¹

¹Serviço de Medicina Física e de Reabilitação - CHP

²USF Nova Via - CHVNG/E

Background & AIM:

Muscular injury is one of the major problems facing today's working population and doctors aren't an exception. In predominant desk based professions, people spend many hours per day in a sitting position. Family doctors are a clear example of this situation. After some hours of consultation, muscle soreness complaints are very frequent, and with the repetitive damage, muscle skeletal injuries are the immediate consequences.

It's known that increasing the flexibility of a muscle-tendon unit promotes better performances and decreases the number of injuries. As a result, it's imperative to use the most effective means to aid in deterring these injuries.

METHODS: Bibliography research and collected data in medical databases.

RESULTS: Literature shows that people who spend many hours in a sitting position, the majority of time in inadequate positions are at higher risk of developing muscle skeletal injuries.

Some randomized controlled interventions have been published showing that great part of this lesions are preventable with posture modifications and periodic intervals doing some simple but effective stretching exercises, necessary to maintain mobility, joint health and sustain a good posture that will reduce the formation of muscle contractors, the most frequent cause of muscle soreness.

Although there's still some discrepancy in the optimal intensity, frequency and duration of the stretching protocols already published, some of these exercises were selected in an attempt to implement a simple stretching protocol to distribute among family doctors so they can do it in a short period of time in an interval between consultation.

CONCLUSIONS: Sedentary lifestyle can be considered as a silent epidemic in nowadays world population. Family doctors are increasingly included in this part of the population.

It is imperative to modify lifestyles, create new routines and promote the need of making frequent stretching exercises during a work day.

From space to medical office: Preventive measures in Osteoporosis

Carolina Martins Moreira¹, Pedro Pinho Caetano², Pedro Cantista¹

¹Serviço de Medicina Física e de Reabilitação - CHP

²USF Nova Via - CHVNG/E

Background & AIM:

Osteoporosis, a chronic and progressive disease of multifactorial etiology, is one of the most common metabolic bone diseases and can result in devastating physical, psychosocial, and economic consequences. Its hallmark is a reduction in skeletal mass caused by an imbalance between bone resorption and bone formation. A similar process occurs in microgravity and was (still is) one of the most difficult to mimic in an experimental setting. However, the research led to the design of the bed rest study as an analog for space flight that mimic microgravity and allows to study, in an controlled environment, new approaches in osteoporosis prevention and treatment.

METHOD: Systematic review in medical databases and lived experience from the author's internship in NASA-UTMB.

RESULTS: Currently, no treatment can completely reverse established osteoporosis. Early intervention with preventive measures can prevent osteoporosis in most people.

Many research have been done in this field, with a huge contribution from astronauts and from bed-rest study data, that shows the importance of exercise in osteoporosis prevention when compared to pharmacologic therapy isolated and also points the best exercise prescription for each situation.

It's important to connect all the information, in order to instruct the patient in a home-exercise program that incorporates the necessary elements for improving posture and overall physical fitness, such aerobic low-impact exercises or impact exercises, weight-bearing exercises or non-weight-bearing, high force exercise and balance training, in an individual program.

CONCLUSIONS: Osteoporosis is often undertreated, in large part because it can be clinically silent before manifesting as fracture. Thus, failure to identify at-risk patients may lead to tragic consequences.

Our gold standard for osteoporosis must focus on preventive measures, namely physical activity, education and rehabilitation that will affect patient outcome and quality of live.

Health Checks for Adults with Intellectual and Developmental Disabilities: Knowledge to Action

Ian Casson¹, Janet Durbin², Meg Gemmill¹, Laurie Greene³, Elizabeth Grier¹, Andrea Perry², Avra Selick², Yona Lunsky²

¹Department of Family Medicine, Queen's University, Kingston, Canada

²Centre for Addiction and Mental Health, Toronto, Canada

³Department of Family Medicine, University of Toronto, Toronto, Canada

Background & Aim

In 2011, Consensus Guidelines on the Primary Care of Adults with Developmental Disabilities¹ were published and distributed to all family physicians in Canada along with a book of clinical tools² to assist with guideline implementation. A key recommendation was to offer an annual comprehensive preventive care assessment, including physical exam - "Health Checks".

This recommendation was informed by international evidence regarding the benefits of Health Checks, along with recent Ontario, Canada data about primary health care in this population³. While adults with intellectual and developmental disabilities (IDD) have the same access to family physicians as adults without IDD, they have lower rates of preventive maneuvers and higher rates of emergency department visits and preventable hospital admissions.

Population health information and clinical practice guidelines provide knowledge for action. But moving guidelines into practice is complex. Implementation projects in three Family Health Teams in Ontario, Canada are evaluating how to put Health Checks into action.

This presentation will describe lessons learned, which may be helpful to other family physicians in enhancing care of adults with IDD in their practices.

Method

Data reflecting the implementation experience were collected through staff surveys, individual and group

interviews and patient medical record audits. Qualitative and quantitative analyses were done.

Results

Barriers and enablers to implementing Health Checks for adults with IDD were identified.

Conclusions

A local champion and a link to a current project in the family practice (e.g., quality improvement programming, outreach to other groups with problems in access to health care services) are helpful. Systematic efforts are required to identify adults with IDD within family practices and to facilitate appointments, especially for those patients without advocates. The content of Health Checks may take several patient encounters to accomplish, but that is consistent with the comprehensive, continuing care model of family practice.

Keywords: intellectual developmental disabilities, health checks, adults

Table 1 - Core components of Health Check

Core component of Health Check:	Process developed to deliver that component:
Identification of patients with IDD	Electronic medical record (EMR) search required verification by staff familiar with practices Diagnostic coding in EMR improved identification of patients in practice
Proactive invitation	Tasking a single clerical person to phone patients for Health Check appointments allowed that person to develop skills to adapt the invitation to needs of patient
Staff resources	Physicians benefitted from orientation and just-in-time resources in the EMR
Delivery of Health Check according to Guidelines	More time needed than usual appointment – shift to a chronic disease management model (e.g., follow-up appointments and an interprofessional team, if available)

The Health Check is a process, not a one-time appointment between a doctor and patient. Core components became evident as implementation progressed

Table 2: Self-described activities of family doctors who did Health Checks

Activity/behaviours:	Percent of respondents:
Modified approach to improve patient communication and comfort	75
Considered developmental functioning of patient	86
Reviewed preventive measures	73
Reviewed medical conditions for which persons with IDD are at risk	68
Involved other team members in care	54
Communication:	
Spoke directly to patient rather than primarily to caregiver	99
Chose appropriate language	98
Considered body language	89
Asked patient/caregiver for helpful strategies	88
Used visual aids or written instructions	54

Health checks were implemented - family doctors and nurses adapted to the special needs and carried out Health Checks according to Guidelines

Table 3 - Acceptability/Feasibility of Health Checks, according to family doctors who did Health Checks (survey respondents = 95)

	Percent of respondents
Health Checks fit with practice's mandate	94

Health Checks benefit persons with IDD 86
 Health Checks would be improved with a more explicit inter-professional approach 84
 Health Checks are feasible to provide given the required time, resources and training 68
 Clinicians and staff felt the Health Check could benefit patients and fit with practices' mandate, but some not were confident about the feasibility of providing Health Checks.

Table 4 – Effect of training on clinicians' and staff's self-assessment

	Percent response before training (N=117)	Percent response after training (N=148)
Felt prepared with skills and training to care for a person with DD	16	34
Familiar with Guidelines	41	71
Familiar with Guidelines Using Guidelines (among those familiar with them)	43	75

Family doctors felt positively about providing care to persons with IDD. But they did not feel knowledgeable about whom they should target, how to modify practice and how to access support or referral services. Training was helpful

P-0588

Analysis of Applications Made For Sports-Pool Medical Report to Family Medicine Clinic

Gulper Ozay, Fusun Artiran Igde, Mustafa F. Dikici, Fusun Yaris

Department of Family Medicine, Ondokuz Mayis University, Samsun, Turkey

BACKGROUND AND AIM: The event of death caused by undue strain during sport activities and occurring 30 seconds to 6 hours according to World Health Organization is called exercise-induced sudden death. This study's aim is to analyze the examinations and results of patients applying for having a medical report for sports-pool to the Ondokuz Mayis University Family Medicine Clinic.

METHOD: This is an incidence study belonging to the data of 195 people applied to the Family Medicine Clinic between November 02, 2011 and December 12, 2012 in order to have a medical report for pool and/or to do sports. In the course of data evaluation, SPSS packet program was used.

RESULTS: The 195 participants of the study included 103 (%53,8) women and 92 (%47,2) men. The average age was 22± 6,6 (10–51). While 158 (%81) people applied for the pool and sports report, 37 (%19) people applied only for sports report. When the blood pressure was measured, the results of 145 (%76,3) people out of 190 were normal. 9 (%4,6) people detected pathology out of 195 patients taken Electrocardiogram (ECG) were consulted to cardiology and were determined that there was not any health problems preventing him/her from doing sports. All 195 people who applied were given medical report stating that there was not any health problems preventing him/her from doing sports and/or swimming in the pool.

CONCLUSION: It is assumed that incidence of sudden cardiac death of young athletes is 0,5–1/100000 in a year. In order to prevent sudden death during and after exercise, it is required to have the history of the athlete and the 1st degree relatives, pay attention to physical examination, take electrocardiogram and, if necessary, determine the cardiovascular diseases by some exercise tests.

Evaluation of The Disease Perception of Patients Who Consulted to Family Medicine Clinic

Gulper Ozay, Fusun Artiran Igde

Department of Family Medicine, Ondokuz Mayıs University, Samsun, Turkey

BACKGROUND AND AIM: Determining the views and perceptions of patients concerning the disease by using Disease Perception questionnaire and evaluating the relation between them and the decision given after consulting to the Family Medicine Clinic.

METHOD: In this cross-sectional study is a questionnaire applied on 57 patients who consulted to our Family Medicine Clinic between May 03-June 26, 2013 with the sociodemographic data. SPSS 21 package program used for the evaluation.

FINDINGS: The 57 participants of the study included 34(59,6) women and 23(40,4) men. The average age was $23,4 \pm 5,1$ (17-40). All 25 persons having signs of burning in the throat since the start of the disease out of 31 patients diagnosed with upper respiratory tract infections (URTI) considered that this symptom was related to the disease. 22 people out of 29 patients having headache considered that this symptom was related to the disease. When the reasons of the disease of the patients with URTI complaints were questioned, it was stated that the disease of 18 people's were cleaved into a microorganism, 11 people's were cleaved into decrease in body resistance. According to short disease perception measure; 4 (7) out of the 57 patients who consulted to our clinic stated that the disease had a serious affect on his/her life, 10 (17,5) of them stated that they had no control over the disease, 23 (40,4) of them stated that the treatment may be quite helpful for the disease.

CONCLUSION: Our study gives rise to thought that while determining a special treatment for the patient, taking into account the disease perception data will increase the participation of the patient in the treatment process and the success of the treatment.

Evaluation of The Knowledge Level of The Faculty of Medicine Students at Ondokuz Mayıs University Concerning Sexually Transmitted Diseases

Gulper Ozay, Fusun Artiran Igde

Department of Family Medicine, Ondokuz Mayıs University, Samsun, Turkey

BACKGROUND AND AIM: We aimed to evaluate the knowledge level of students of the faculty of medicine at Ondokuz Mayıs University concerning sexually transmitted infections (STI) and on their differences in terms of sociodemographic variables.

METHOD: In this cross-sectional study, sociodemographic datas which consisted of 26 questions and STI Information Test adapted from 40-question STI/Human Immunodeficiency Virus(HIV) Pretest that was used to determine sexual health education knowledge levels of students in Canada, was applied to 1st and 6th year undergraduate medical students at Ondokuz Mayıs University, between January 23, 2015 and February 24, 2015. The data was evaluated by using SPSS 20 program.

RESULTS: Among 103 participants, 81 (78,6) of them were in their 1st year and 22 (21,4) of them were in their 6th year. When the source of information was asked, 27 (33,3) of 1st year undergraduate students stated that they learn about STI on internet, 19 (86,3) of 6th year undergraduate students stated that they learned about STI at university. 64 (61,5) undergraduate students stated that information about STI should have been provided during high school education. The highest score one could get in the information test on STI was 36, the average correct answer of the participants which was converted into the score was $12,6(0-28) \pm 4,3$, average wrong answers was $13,6(0-21) \pm 4,9$, average no idea answers was $9,7(0-36) \pm 7$.

CONCLUSION: In this research we have found out that the knowledge level of participants on STI is insufficient in general. It is advised that awareness level on STI should be increased and sexual health education should be widespread with regards to accession to reliable information sources.

Women, Call your Men! - Preventive care in the Slovak Republic

Beata Blahova¹, Jana Bendova², Peter Gazdik³, Kamila Bolanovska⁴, Melania Rynikova⁴, Eva Tarbajovska⁴, Michaela Machacova⁵, Stefan Krnac⁶

¹General practitioner, Krompachy, Slovak republic

²General practitioner, Velky Biel, Slovak republic

³General practitioner, Kapusany, Slovak republic

⁴General practitioner, Presov, Slovak republic

⁵General practitioner, Topolcany, Slovak republic

⁶General practitioner, Hrinova, Slovak republic

BACKGROUND: The number of cardiovascular diseases and cancer are all increasing in the Slovak Republic with cardiovascular diseases the first and cancer the second leading cause of death. One method of reducing the mortality of this disease is through earlier diagnosis. That is why preventive care is so important. According to demographics there are more men than women aged under 50 and more women than men over 50. Many doctors have observed that fewer men visit doctors' offices than women.

AIM: The first aim of the study is to find out how many men and women undergo preventive examinations. The second is to try to raise this number through women, who we know to be more frequent visitors.

METHODS: 7 medical offices participated in our cross sectional study. 1757 patients underwent a routine biennial preventive examination. Screening of colorectal carcinoma was performed in 871 patients. The first phase was performed from January to June 30th 2014. The second phase will be performed from January to June 2015.

RESULTS: We found that of 1757 examined patients, 1078 (61.3%) women and 679 (38.64%) men. Of the 871 patients screened for colorectal carcinoma 547 (62.8%) were women and 324 (37.1%) men. The second stage of our research is now in process. We will publish our findings for the second stage in July 2015.

CONCLUSION: Knowing that women visit medical offices more often than men, we decided to act through them. We designed a poster which is on display in our offices and we also verbally invite men through women, who are encouraged to call their male relatives and friends. Although according to demographic trends there are more women than men over the age of 50, the difference in numbers is not as big as the difference between numbers of women and men being examined.

Epidemiological profile in HIV-infected patients who start antiretroviral therapy

María Fernández Zambrano¹, María Cristina Garrido Laguna¹, Javier Pérez Stachowski², Javier De La Torre Lima²

¹General Practitioner, Hospital Costal del Sol, Marbella, Andalucía, SPAIN

²Department of internal medicine, Hospital Costa del Sol, Marbella, Andalucía, SPAIN

OBJECTIVE: To analyze the epidemiological profile at present in HIV-infected patients who start antiretroviral therapy (ART).

METHODS: A retrospective observational study was performed on adult HIV-infected patients who began their first ART regimen from 1 January 2012 to 1 January 2014 in Costa del Sol (South of Spain). Descriptive statistics were obtained using frequency tables for the categorical variables and measures of central tendency and dispersion for the quantitative ones (median and interquartile range-IQR)

RESULTS:

664 patients were included, 572 males and 92 women. The average age for diagnosis was 37 years (+/- 10 SD). Regarding HIV risk factors, we found 6.8% of IDUs, 31.8% heterosexual and 57.21% homosexual.

At the beginning of the treatment we obtained an average of 326 CD4. 50% of the patients at diagnosis were less than 350 CD4. Regarding hepatotropic virus serology, 43 (6.5%) were HBsAg + and 50 (7.5%) HCV RNA +. The treatment of choice for first-line ART was efavirenz / emtricitabine / tenofovir on 36% of patients, followed by Efavirenz (12.3%) and Emtricitabine / Tenofovir disoproxil / Darunavir (12.3 %). The average lead time from the diagnosis to the start of the treatment was 4 months.

CONCLUSIONS:

Among the patients in our HIV-naive cohort, a majority of infected males were found, the higher percentage of them were homosexual, and we have also observed a decrease on infected addicted to intravenous drugs.

At the moment of diagnosis, the average age was 37 years old and the mean CD4 in half of the patients were less than 350 CD4, what may cause serious infections, so we consider it a late diagnosis.

Respecting the treatment, we can conclude that an early ART was initiated and the response to this was very positive.

Workplace stressors and its effects to perception of depersonalization and job dissatisfaction in physicians

Nurka Pranjic¹, Sanda Kreitmayer Pestic², Ljiljana Maleš Bilić³, Anja Pranjic⁴

¹Department of Occupational Medicine, Tuzla University School of Medicine, Tuzla, Bosnia and Herzegovina

²Educational Centre of Family Medicine, Tuzla University School of Medicine, Tuzla, Bosnia and Herzegovina

³Department of Occupational Medicine, School of Medicine, Banja Luka University, School of Medicine, Banja Luka, Bosnia and Herzegovina

⁴Postgraduate study of Faculty of Economics of University of Tuzla, Tuzla, Bosnia and Herzegovina

Depersonalization is described as suffering from episodes of surreal experiences. Some of these experiences have been also reminiscent of panic attacks and paroxysmal anxiety.

AIM: To examine the prevalence of workplace stress, depersonalization and job dissatisfaction; to assess the association between differential levels of distress and job dissatisfaction on depersonalization among physicians in Bosnia and Herzegovina.

METHODS: A cross-sectional study was conducted in period January 2014- January 2015. Questionnaires were distributed to a convenience sample of 715 physicians employed in Hospital Clinical Centers and Health Centers in Tuzla Region. The response rate was 71% (n=511). Data were collected using the Occupational Stress Assessment Questionnaire (OSQ) and the Maslach- Burnout Inventory.

RESULTS: Twenty three percent of respondents (n=511) reported a high level of workplace stress, 13% perceived a high level of job dissatisfaction and 15% a high level of depersonalization. Feeling of moderate level of depersonalization was present in about 49% of respondents (about half of physicians). Perception of depersonalization predicted following stressors: need to using knowledge and skills during working tasks ($\beta=0.132$; 95% CI, -0.032-0.508) and work has phases that are too difficult ($\beta=0.136$; 95% CI, -0.001-0.574). Job dissatisfaction was predictor for perception of depersonalization ($\beta=0.238$; 95% CI, 0.236-0.816).

CONCLUSION: The study results underline the importance of continued education, work organization, improving job satisfaction on way to protect development of depersonalization in physicians.

Comparison of knowledge, attitude and practice of premarital thalassemia screening among thalassemia patients and public at Selangor: a protocol paper

Dayangku Hayaty Awg Dzulkarnain, Maliza Mawardi, Puteri Shanaz Jahn Kassim, Sazlina Shariff Ghazali

Department of Family Medicine, Universiti Putra Malaysia, Serdang, Selangor, Malaysia

INTRODUCTION: Thalassemia is a public health problem in Malaysia. Since the implementation of National Thalassemia Screening in Malaysia in 2004, the response towards thalassemia screening was poor and there were few studies done in Malaysia shows lack of public awareness against thalassemia screening. However there is no specific study focus at comparison of knowledge, attitude and practice towards premarital thalassemia screening especially at young adult population between those who are diagnosed with thalassemia and public who never been screened. The main objectives of this study is to determine the gap of knowledge, attitude and practice of premarital thalassemia screening among thalassemia patients and public for future justification and recommendation for mandatory premarital screening in Malaysia.

METHODS: This is a cross sectional study conducted on thalassemia patients who attended thalassemia day care clinic at Hospital Ampang and individual who attended government health clinic in district of Hulu Langat. This study will be conducted for 24 months and expected data collection is in July 2015 till January 2016. Estimated sample size is 800(400 from thalassemia patients who attended thalassemia day care clinic at Hospital Ampang and 400 individual who attended government health clinic in district of Hulu Langat). The questionnaires that will be used in this study are include the information of socio-demography, knowledge, attitude and practice towards pre-marital thalassemia screening. Data will be analysed using SPSS 21.

CONCLUSION: The outcome of this study will be a pillar for development of model of intervention of knowledge, attitude and practice towards premarital thalassemia screening in future.

educational intervention improving the screening and classification of obesity and overweight in a primary health care centre

Anna Forcada Arcarons, Laura Almendros Plana, Silvia Altimiras Rovira, Josefa Soler Arau, Diana Sanchez Martinez, Engracia Costa Atienza, Alícia Díaz Pilco
institut català de la salut

BACKGROUND

An excess of body fat is a public health problem that affects 49.2% of the population (35.9% overweight and 13.9% obesity) according to the health survey of Catalonia and provides increased morbidity and mortality in persons who suffer. The body mass index (BMI) is widely used for the diagnosis of overweight and obesity.

AIM

Determine whether an educational intervention improves the registration of obesity, overweight and BMI. There is an under-diagnosis' record of these pathologies in our Primary Health Care Area. The prevalence in our area of body fat's excess in last April was of 12.41%.

METHODOLOGY

Study before and after an Educational Intervention made to the team and led to the health professionals. This Intervention consisted in remember the management of these pathologies and how to catalogue in our informatic program.

Determine the new prevalence of body fat's excess after Intervention and analyze if improves its record in the computer program: full intelligence active program eCap (registration BMI), and logging diagnostic codes (overweight and obesity).

RESULTS

There is an increase in the diagnosis of obesity and overweight after intervention. The baseline prevalence was 12,41% and 12,82% of the final.

Incident cases: there are 78 new cases, compared to the prevalent represent 3,7%.

CONCLUSIONS

The educational intervention can increase the record of these diseases although in our study is not statistically significant. We need other strategies to raise professionals, because it's a modifiable health problem that is related to many other important diseases (Diabetes, Hypertension...).

Between the intervention and analysis of the data was not long so perhaps was the cause of not statistically significant.

Measurement of neck perimeter as a predictor os cardiovascular risk

José Carlos Sánchez Perez, Nayade Jorge Matin, José Ángel Sanchez Ortiz, Maria Ángeles Castaño Fuentes, Maria Rosa Sánchez Perez, Rocio Gil Ruiz
Andalusian Health Service

OBJECTIVE:

Studying the capacity of the measurement of neck perimeter as predictor of cardiovascular risk in patients with obesity, arterial hypertension, dyslipidemia, type 2 diabetes and/or tobacco use.

MATERIALS-METHODS:

Random samples were obtained from patients at 10 health clinics, all of whom presented some cardiovascular risk factors: arterial hypertension, dyslipidemia, obesity, type 2 diabetes and tobacco use. The following parameters were measured: age, sex, weight, waist size and bodily mass index (BMI), abdominal perimeter, neck perimeter. The samples were divided according to obesity: obese patients (BMI > 30) and not obese patients (BMI < 30). The inferential statistics were recorded with R commader program,

RESULTS:

The samples were of 251 individuals, 117 men (46,61%) and 134 women (53,39%).They were separated into 2 groups according to BMI, 120 obese (47,81%) and 131 not obese (52,19%).No statistical differences was found between the 2 groups related to the following parameters: age, sex, waist size and tobacco use.

There was, however, a significant difference found between the average neck ann abdominal perimeters of the 2 groups.Analysis of correlation between 3 variables: BMI, neck perimeter and abdominal perimeter, was record (table 1).Linear regression between neck and abdominal perimeter was analyzed with de following equation:
Abdominal Perimeter: $45,67 + 150 \text{ neck perimeter}$.

CONCLUSIONS:

A correlation exists between BMI, abdominal perimeter and neck perimeter.It would be convenient to pursue an enhanced study with a greater sample size to obtain more significant statistical data, hereby enabling the establishment of a more precise correlation.
It would already have practical importance that neck perimeter is faster and easier to obtain in a clic that BMI or abdominal perimeter.

Tobacco, an enhancer?

Nayade Jorge Martin, José Ángel Sánchez Ortiz, José Carlos Perez Sánchez, María Ángeles Castaño Fuentes, María Rosa Sánchez Perez, Juan Carlos De Sola Jurado
Andalusian Health Service

OBJECTIVE:

Determine whether or not being a smoker increases risk of cardiovascular disease an other related risk factors.

MATERIAL-METHODS:

Samples have been randomly from 16 patient facilities at a Health Clinic with at least one of the following illnesses: Arterial Hypertension, Diabetes, Obesity, Dyslipidemia, The samples were collected from both smokers and non-smokers. In both cases, circumstances such as age, weight size and bodily mass index were taken into account. For statistical analysis, R commander program was utilized with Student T, Fisher F and Chi- squared.

RESULTS:

The sample come from a total of 251 people; 76,1% were smokers, of which 45,4% were male and the other 54,5% were female. The other 23,9% of all subjects were non-smokers, 50% of whom were men and the other 50% women

We found a significant correlation between age and smoking tendencies. The smoking population generally consisted of younger people (X= 57,01 years) as opposed to the non smokers (X= 62,22 years) with an confidence interval of 95% of (1,74 - 8,66) for the difference. There is almost no significance of the relation between smoking and obesity (p = 0,059) and smoking and arterial hypertension (p = 0,075) nor was there any relevant or apparent correlation between smoking and the other previously mentioned illnesses, (see table 1). There was no relation between the smoking variable and the numerous cardiovascular risk factors present in each individual (p <0,05), (see table 2). After individually studying the smoking variable with respect to the other cardiovascular risk factors, no relation was found.

CONCLUSION:

Given the inverse relation between tobacco use and age it'd be advisable for carry out new studies aimed towards discovering wether or not said correlation is affected by sanitary educación, cardiovascular risk factors number...

Health promotion in a rural pre-settlement in the Federal District - Brazil

Ubirajara José Picanço De Miranda Junior¹, Isabelle Cristine De Jesus Macedo¹, Izza Dantas Cano¹, Carolina Martins Pereira¹, Larissa Dos Reis Rodrigues¹, Bruno Souza De Faria¹, Fernando Erick Damasceno Moreira²

¹School of Health Sciences of the Federal District - Brazil

²Health Secretariat of the Federal District - Brazil

Introduction - Students of medicine at the 1st series of the College of Health Sciences School (ESCS) participated in a social action to promote health in a rural pre-settlement, in which health care, sanitation and housing conditions are poor aimed to to describe this experience. **Method** - Realization of activity planned by a Family Health Team and the ESCS students with about one hundred families residing in the rural pre-settlement. Most homes have structure and poor hygiene, including the location of the action that took place in a wooden shed with uneven floor, making the setting of scales, chairs and tables. The team organized the location, strategically arranging the equipment to be used. There were two rooms, a waiting and screening (glycemic evaluation, blood pressure and nutritional status) and the other of vaccination, fluoride application and medical consultation. For better use and learning, there was rotation of students in the various functions. **Results** - The activity was important because it was seen the performance and operation of a foothold to a needy society. The theoretical knowledge was applied in the real scenario based on educational guidelines recommended by the ESCS. **Conclusion** - As a result, students have acquired the ability to observe the patient's perspective in relation to their difficulties, which allowed them to take a humanitarian behavior, expanding the focus to address not only the disease, but the subject and its social environment as well as the relevance of experiences of learning about the relationship of the health team with society.

Prospective cohort study of smoking cessation program in the "real world"

Ana Marqueño Ellacuría¹, Marc Tarín Martí¹, María Cordobés Millán¹, Sílvia Crespo Blas¹, Angela Inés Vieira Rodríguez¹, Rosario Hernández Ibáñez², José Miguel Baena Díez², Cristina Serrano Morales³, Natividad Martín Peña³

¹Resident de Medicina Familiar i Comunitària, CAP La Marina, Barcelona, Espanya

²Metge de Família, CAP La Marina, Barcelona, Espanya

³Infermera, CAP La Marina, Barcelona, Espanya

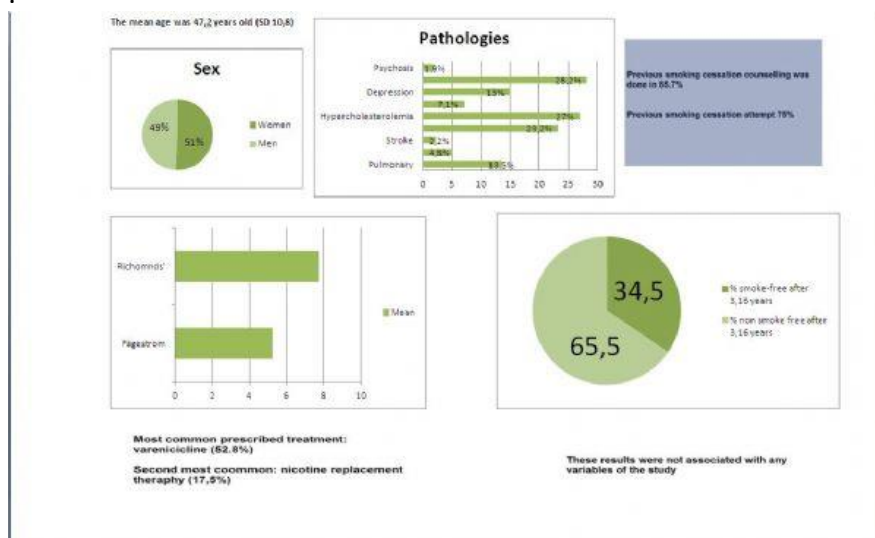

BACKGROUND AND AIM. Smoking is a major cause of morbidity in developed countries. The aim of study was to describe the characteristics of patients included in a smoking cessation program, and to estimate the "real-world" effectiveness in general population.

METHODS. We conducted a prospective cohort study in 264 adult smokers who participated in a smoking cessation program in a primary care centre. Patients were referred to the first visit with a trained nurse. The rest of the visits were performed by general practitioner or a nurse. The protocol included the following variables: age, gender, chronic pulmonary disease, cardiovascular disease, cardiovascular risk factors, psychiatric disorders, previous smoking cessation counseling, smoking cessation attempts, Fageström and Richmonds' scales, carbon monoxide (CO) in expired breath, and pharmacologic treatment.

RESULTS. The mean age was 47.2 years old (SD 10,8), and 50.9% were women. The prevalence of pathologies were: pulmonary disease 13.5%, ischemic cardiopathy 4.8%, stroke 2.2%, hypertension 23.2%, hypercholesterolemia 27.0%, diabetes mellitus 7.1%, depression 15.0%, anxiety 28.2% and psychosis 1.9%. Previous smoking cessation counseling was done in a 85.7% of the patients, and 75% had a previous attempt. The mean of the Fageström scale was 5.26 (SD 2.18), and the Richmonds' mean was 7.71(SD1.89). The mean of carbon monoxide (CO) in expired breath was 3.81 (SD 2.16). The most common prescribed treatment was varenicline (52,8%), and nicotine replacement therapy (17,5%). The 34,5% of the patients (95% confidence interval 28.6% to 40.9%) remained smoke-free after a 3.16 years of follow-up. These results were not associated with any variables of the study.

CONCLUSIONS. This study demonstrates the effectiveness of a smoking cessation program in a long term cohort in the "real world". Abstinence rates were similar to previous studies. Remark that psychiatric disorders' prevalence was high. Instead, cardiovascular diseases had a low prevalence.

P-0600

Migration between teaching scenarios and family risk in primary health care: An experience report

Ubirajara José Picanço De Miranda Junior, Ananda Dos Santos Conde, Thiago Cavalcante Magalhães, Victoria Veiga Ribeiro Gonçalves, Jessica Dos Santos Huang, Ana Luisa Ataíde Moraes
Superior School of Health Sciences of the Federal District - Brazil

Background and AIM: The School of Health Sciences - ESCS, located in the Federal District - Brazil, adopts active learning methodologies and offers an educational unit called "Interaction Teaching-Service-Community (IESC)", that promote actions of primary health care. In 2013 this educational unity changed its teaching scenario due to social instability, violence, and poor infrastructure, that made the home visits little profitable to students, making it difficult to bond with the families, but provided an opportunity to compare family risk in these two scenarios instead. **METHOD:** Quantitative, observational and cross-sectional study from secondary data of the Brazilian Informational System of the Primary Health Care in the two areas surveyed in 2013. It included 25% of records randomly selected from both scenarios, in a total of 104 records in the first place (Vila Dnocs) and 119 in the second (Vila Basevi). From that followed an evaluation according to a scale called the Family Risk Scale. An analysis of the records was made through discussions on the scores obtained from this scale of risk. **RESULTS:** According to the analysis, the maximum family risk in Vila Basevi was that of 25%, while in Vila Dnocs it was 12.54%. **CONCLUSION:** It was supposed that the families of the Vila Dnocs were at a higher family risk, due to the violence and, consequently, greater social vulnerability. The sanitation criterion directly shaped the results, since the Vila Basevi does not have such service and Vila DNOCS does. The Vila Basevi began the research with a score of three points ahead of the other community. Even though it had a greater family risk in the results, the problem is mainly focused on the inadequate sanitation, which is more feasible to solve, while Vila Dnocs shows a lack of social facilities, making the situation more difficult to resolve.

An Unusual Abdominal Pain

Maria Giovanna D'angelo, Paula Pilar Rodriguez Casal, Carmen Arca Pichel, Santiago Perez Cachafeiro
Department of Primary Care, Integrated Management Area Pontevedra-Salnes, Galicia, Spain.

INTRODUCTION: Colorectal cancer (CRC) is a common and lethal disease. It is the second most commonly diagnosed cancer in women and third most common in men. The risk of developing CRC is influenced by both environmental and genetic factors.

CASE DESCRIPTION: A 56-year-old woman with an irrelevant pathological family history. Personal history: dyslipidemia, psoriasis, tonsillectomy and uterine myoma. No drug allergies. No toxic habits. Medical treatment: Simvastatin.

She attends her general practitioner (GP) presenting two nocturnal episodes of fever in last weeks and pain in the right hypochondrium that bears relation to movement; physical examination revealed minimal hepatomegaly. Three months ago she had gone to her GP complaining of abdominal pain and constipation and her physical examination and clinical analysis were normal. We requested abdominal ultrasonography that revealed focal hepatic lesions suggestive of metastasis. We decided to contact the Emergency Department and Gastroenterology. Laboratory tests in ER showed, iron deficiency; hormonal and tumor markers were normal. The abdominal and pelvic CT scans with contrast administration confirms focal liver lesions, and also shows loco-regional lymphatic nodes, advising rule out rectal cancer. EUS confirmed CRC. Finally, genetic testing showed KRAS mutation.

CONCLUSIONS:

Early detection and secondary prevention is important in the CRC. The GP is the main link in the health action to combat cancer, although primary prevention is not always easy. Screening of asymptomatic individuals for CRC is advocated by major societies and preventive care organizations, including the Council of the European Union based on the European Code Against Cancer. The screening tests for CRC include the fecal occult blood test and look for criteria suspected of CCR. It is also important to screening in patients with a family history of CRC and ensuring the fulfillment tracking polyps.

Evaluation of Patients Admitted to the Periodic Health Examination Clinic of Family Medicine on Ondokuz Mayıs University, Samsun, Turkey

Gulumser Kir Dogru, Fusun Artiran Igde, Mustafa Fevzi Dikici, Fusun Yaris
Department of Family Medicine, Ondokuz Mayıs University, Samsun, Turkey

Background & AIM: Periodic health examinations (PHE) aims applied to healthy individuals at regular intervals, by identifying personal spesific risks aims early diagnosis and detection of diseases that can be treated. The aim of our study of patients admitted to our recently PHE outpatient clinic is to determine the general characteristics. **METHOD:** 40 cases who admitted to the PHE Clinic of Family Medicine on Ondokuz Mayıs University between the date of December 2014- February 2015 were included in the study. Necessary data were collected from files of patients.

RESULTS: 47.5%(n=19) of the cases were female, 52.5%(n=21) were male. The mean age of participants was 40.7±15.1. The majority of patients who applied PHE outpatient clinic didn't have any active complaint however abdominal pain, widespread pain, fatigue, headache was the chief complaints. When evaluating behavioral lifestyle 22.5%(n=9) of patients were using cigarettes and the majority of users were found male. 6(15%) participants are using social drinking alcohol level. 9(22.5%) participants had a history of malignancy in the first and second degree relatives. 11(27.5%) participants had a family history of coronary artery disease. 6(31.6) of the female participants have a mammogram at least a time. 8(42.1) female participants was doing a self breast exam once a month. 5(26,3) of the participants had at least once a pap-smear care. Systolic blood pressure of the participants was 121,7±14.07 while diastolic blood pressure was 78,7±8,2. Systolic blood pressure was higher in males while diastolic blood pressure was higher in females. The average of body mass index (BMI) was 26.88 ±5.8; BMI was higher in females. The results of the examinations and investigations 10(25%) patients had recommended intermittent PHE. Colonoscopy was planned to six participants. Mammography and pap-smear was planned for 10 female participants.

CONCLUSION: PHE is an important step in preventive care.

P-0603

The association between coronary calcification and adenomatous polyps of colon in Korean adults

Hongbae Kim¹, Yongjae Lee², Jaeyong Shim², Hyeree Lee²

¹Department of Family Medicine, Myongji Hospital, Goyang, Republic of Korea

²Department of Family Medicine, Yonsei University, Seoul, Republic of Korea

Background and Aim

Adenomatous polyps of colon is a precancerous lesion. Many studies have shown that the adenomatous polyps of colon and disease share several common risk factors. This cross-sectional study aimed to investigate whether coronary calcification is associated with the adenomatous polyps of colon.

Method

Among 1637 Korean adults, we examined the association between coronary calcium score (CCS) as a measurement of coronary calcification and the presence of adenomatous polyps of colon via multi-detected row computed tomography (MDCT) and colonoscopy, respectively. CCS values were categorized as follows: 0, 1—17, 18—105, or ≥106. The odds ratios (ORs) and 95% confidence intervals (CIs) for the presence of adenomatous polyps of colon were calculated across CCS groups.

Results

After adjusting for confounding variables, the adjusted ORs (95% CIs) for the presence of adenomatous polyps of colon in each of the four CCS groups were 1.00 (reference), 1.44 (0.91—2.33), 1.88 (1.15—3.01) and 3.61 (2.23—5.74). And higher CCS values were associated with multiple polyps ($p \leq 0.001$), villous histologic features or high-grade dysplasia ($p = 0.02$), and advanced adenomatous polyps ($p \leq 0.001$).

Conclusions

A higher level of CCS was found to be strongly and independently associated with the presence of adenomatous polyps of colon in Korean adults. This finding suggests that people at high risk for coronary atherosclerosis through MDCT should be considered for further evaluation of adenomatous polyps.

Keywords: coronary calcium score, adenomatous polyps of colon, cross-sectional study

Comparison of the prevalent adenomatous polyp of colon according to the coronary calcium score

The prevalence of adenomatous polyps of colon increased as CCS values increased as follows: 17.6% (224/1271), 31.7% (39/123), 37.7% (46/122), and 58.7% (71/121) for CCS groups 0, 1–17, 18–105, and ≥106, respectively ($p < 0.001$).

Characteristics according to coronary calcium score value

	CCS value				P-value
	0 (n=1271)	1-17 (n=123)	18-105 (n=122)	≥106 (n=121)	
Age (years)	50.3 ± 8.4	55.2 ± 8.9	57.2 ± 9.0	61.6 ± 8.8	<0.001
Male sex(%)	51.7	77.6	87.2	86.0	<0.001
Current smokers(%)	35.6	29.3	23.2	21.5	<0.001
Body mass index(kg/m ²)	23.1 ± 2.8	24.5 ± 2.8	24.0 ± 2.4	24.5 ± 2.4	<0.001
Systolic BP (mmHg)	119.5 ± 15.9	123.7 ± 16.8	125.0 ± 14.8	128.6 ± 13.1	<0.001
Diastolic BP (mm Hg)	74.5 ± 9.6	77.9 ± 8.3	78.8 ± 9.1	80.5 ± 7.8	<0.001
hsCRP(mg/L)	1.4 ± 2.4	1.7 ± 2.1	1.6 ± 2.3	1.9 ± 2.8	0.16
Fasting glucose (mg/dL)	92.0 ± 13.7	95.6 ± 12.6	99.2 ± 21.4	105.8 ± 29.8	<0.001
Total cholesterol (mg/dL)	201.4 ± 78.2	197.5 ± 69.8	210.4 ± 80.2	205.9 ± 67.3	0.46
Triglyceride (mg/dL)	113.1 ± 70.3	124.7 ± 68.5	134.8 ± 83.1	125.9 ± 56.4	0.002
HDL cholesterol (mg/dL)	47.8 ± 11.4	41.8 ± 9.9	54.3 ± 12.0	48.8 ± 17.2	0.42
LDL cholesterol (mg/dL)	122.4 ± 30.0	125.8 ± 30.5	124.7 ± 31.2	121.0 ± 31.4	0.53
ALT (IU/L)	23.9 ± 15.2	29.1 ± 18.3	24.6 ± 10.0	27.7 ± 14.7	<0.001

Table 1 shows the demographic and biochemical data for all subjects according to CCS group. The average age was 51.7 ± 9.5 years. The mean BMI (kg/m²) was 23.5, and the percentage of patients that were current smokers was 32.6%. The mean age, number of male subjects, BMI, SBP, DBP, FPG, and ALT level were higher in the CCS ≥106 group, whereas the percentage of current smokers was lower in that group. Triglyceride levels were highest in the CCS 18-105 group. Abbreviations: BP = blood pressure; hsCRP = high-sensitive C-reactive protein; HDL= high density lipoprotein; LDL = low density lipoprotein; ALT =alanine aminotransferase. Data are expressed as the mean ± standard deviation or percentage. P-value was calculated by ANOVA test for continuous variable or chi-squared test for categorical variable.

Odds ratio and 95% confidence intervals for adenomatous polyp of colon according to CCS value

	CCS value			
	0	1-17	18-105	≥106
Model 1	1.00	2.16 (1.41 – 3.34)	2.92 (1.90 – 4.38)	6.77 (4.54 – 10.08)
Model 2	1.00	1.64 (1.03 – 2.56)	2.28 (1.41– 3.54)	4.45 (2.82– 7.03)
Model 3	1.00	1.44 (0.91 – 2.33)	1.88 (1.15 – 3.01)	3.61 (2.23– 5.74)

Table 2 shows the risk of developing adenomatous polyps according to CCS values. After adjusting for all confounding factors (age, sex, smoking status, body mass index, blood pressure, fasting glucose level, total cholesterol, triglycerides, HDL cholesterol, LDL cholesterol, ALT and hs-CRP) the adjusted OR (95% CI) for having adenomatous polyps in the highest CCS group was 3.61 (2.23 – 5.74) compared to the lowest group. Model 1: unadjusted. Model 2: adjusted for age, sex, smoking status, body mass index, blood pressure, fasting glucose, total cholesterol, triglyceride, HDL- cholesterol and LDL-cholesterol Model 3: adjusted for age, sex, smoking status, body mass index, blood pressure, high sensitive C-reactive protein, fasting glucose, total cholesterol, triglyceride, HDL-cholesterol, LDL-cholesterol and alanine aminotransferase High sensitivity C-reactive protein and triglyceride were log transformed for analysis. Reference values of all variables are lowest quartile except HDL-cholesterol. Reference value of HDL-cholesterol is highest quartile.

Characteristics of adenomatous polyp of colon categorized by CCS

	CCS value				p-value
	0 (n=1271)	1-17 (n=123)	18-105 (n=122)	≥106(n=121)	
Colon polyp (%)	224(17.6)	39(31.7)	46(37.7)	71(58.7)	<0.001
Size(mm)					0.67
<10	202 (90.2%)	36 (92.3%)	44 (95.7%)	64 (90.1%)	
≥10	22 (9.8%)	3 (7.7%)	2 (4.3%)	7(9.9%)	
Number					<0.001
<3	198 (88.4%)	31 (79.5%)	34 (73.9%)	41 (57.7%)	
≥3	26 (11.6%)	8 (20.5%)	12 (26.1%)	30 (42.3%)	
Villous feature or high-grade dysplasia					0.02
Yes	0(0%)	0(0%)	1(2.2%)	4(5.6%)	
No	224 (100%)	39 (100%)	45 (97.8%)	67 (94.4%)	
Advanced lesion					<0.001
Yes	39 (17.4%)	9 (23.1%)	13 (28.3%)	32(45.1%)	
No	185 (82.6%)	30 (76.9%)	33 (71.7%)	39(54.9%)	

As shown in Table 3, compared to the group with a CCS of 0, higher CCS values were more frequently associated with multiple polyps (p<0.001), villous histologic features or high-grade dysplasia (p=0.02), and advanced adenomatous polyps (p<0.001). However, there was no correlation between CCS value and polyp size. And no association between CCS value and advanced adenomatous polyps was found.

P-0604**Doctor's role in colorectal cancer screening**

Gintare Jakstaite¹, Neringa Burokiene¹, Virmantas Kvedaras²

¹Clinics of Internal Diseases, Family Medicine and Oncology, Faculty of Medicine, Vilnius University, Vilnius, Lithuania

²Department of Econometric Analysis, Faculty of Mathematics and Informatics, Vilnius University, Vilnius, Lithuania

BACKGROUND: To evaluate impact of family doctor on rate of colorectal cancer screening.

METHODS: 530 health's histories were analyzed retrospectively in the Vilnius University Hospital Santariskiu Klinikos (VUL SK) Family Medicine Center. The participation in the colorectal cancer screening was assessed for two time periods: July 2009 – July 2011 and August 2011 – September 2013. Correlations between the number of visits to a family doctor and participation were analyzed. Colorectal cancer screening results of four (A, B, C, D) family doctors were compared.

RESULTS: 73.4 percent of the patients did iFOBT test during the first period and 64.5 percent during the second period in VUL SK Family Medicine Center. Patients, who did the test during the first period, were significantly less active during the second one. Family doctor A had significantly higher rate of patients who did iFOBT test than other family doctors. Correlation between visits to a family doctor and participation were found (probability of participation is increasing with number of visits).

CONCLUSION: Family doctors play a very important role in screening programs. Invitations to participate in screening sent to patients who rarely visit a family doctor should lead to better results of the colorectal cancer screening program.

P-0605**Colorectal cancer screening in Lithuania**Gintare Jakstaite¹, Neringa Burokiene¹, Virmantas Kvedaras²¹Clinics of Internal Diseases, Family Medicine and Oncology, Faculty of Medicine, Vilnius University, Vilnius, Lithuania²Department of Econometric Analysis, Faculty of Mathematics and Informatics, Vilnius University, Vilnius, Lithuania

BACKGROUND: To evaluate the extent of colorectal cancer screening in Vilnius University Hospital Santariskiu Klinikos (VUL SK) Family Medicine Center and in Lithuania in general.

METHODS: 530 health histories were analyzed retrospectively. The results of colorectal cancer screening during the period from July 2009 to September 2013 were assessed in VUL SK Family medicine Center. Statistical data from the Ministry of Health of Republic of Lithuania was interpreted.

RESULTS: 88.3 percent of patients did iFOBT test by themselves at least once between July 2009 and September 2013 in VUL SK Family Medicine Center. 59 iFOBT tests were found positive, 49 colonoscopies were performed, 26 biopsies were taken. Premalignant changes were found for 23 patients. Carcinoma was diagnosed in 1 case. About 160 thousands patients made iFOBT test in Lithuania during the period between July 2009 and July 2011. The results were positive for 12118 patients. 7730 colonoscopies were performed and 2635 biopsies were taken. 186 colorectal carcinomas were diagnosed.

CONCLUSION: Rate of participation in colorectal cancer screening is high in comparison to literature's data, but only two thirds of iFOBT-positive patients perform colonoscopy.

An epidemiological study in obese patients assisting to a dietetic therapeutic programme in Primary Care

Cristina Navarro Robles¹, María Cristina Garrido Laguna¹, María Fernández Zambrano¹, Agustín Benítez De La Poza¹, Maria Dolores Romo², Idoia Arrillaga Ocampo¹, Irene Padial Reyes¹

¹General Practitioner, Las Lagunas Health Center, Mijas Costa, Andalucía, SPAIN

²Psychologist, Las Lagunas Health Center, Mijas Costa, Andalucía, SPAIN

INTRODUCTION: Knowing the dietetic habits in obese patients is essential for the achievement of a variation in the daily life habits.

OBJECTIVE: to analyze the epidemiological profile in obese patients who start an interventional group.

METHODS: A retrospective observational study in obese patients was performed between 2013- 2014 in Mijas Costa Health Center (Málaga, Spain).

RESULTS: The programme was composed of 78 patients, 60 women and 18 men, including 86% of obese patients (IMC > 30).

In this study we observed that 38.5% eat only three meals a day. 83% reported eating at home and 64% accompanied. It is observed that 44% eat between meals despite having a fixed schedule for main meals (78%). Most of those attending the program are responsible for the family diet, 68% was in charge of cooking and 76% perform daily shopping. 53% recognize continuous sensation of appetite. 68% acknowledged binge eating. The way of cooking of the 30% was making stew dishes against an 11% who reported eating grilled food.

We have found that 72% of our patients tried previous unsuccessful diets.

CONCLUSIONS: Among patients in our cohort, we found a minority of them with BMI 25-30 so we conclude that the programme would be more useful in early stages, preventing progression to morbid obesity, when it is more complicated that the programme could be successful.

Most of our patients are responsible of cooking and doing the shopping, as well as they eat at home with fixed schedules and accompanied, therefore bad habits extend to the household and the results of the intervention come indirectly to the patient family environment.

About the realization of previous diets, most admitted having done many previous diets without results. In addition we observed low adherence to the Mediterranean diet with an increase of unhealthy habits.

¹Community health centre Ljubljana, Ljubljana, Slovenia

²Community health centre dr. Adolfa Drolca Maribor, Maribor, Slovenia

Because of prolonging life span and the increasing number of people with various chronic diseases the health policy in Slovenia took a big step forward in 2011 regarding solving the current issues in this field by introducing a "model practice" (MP) together with the Ministry of Health, which emphasises the organisation and operation of primary health care activity, namely the field of family medicine. Model practice is a type of family practice, in which a doctor and nurse are joined by a nurse practitioner. The main purpose of model practices is to carry out thorough prevention of chronic non-communicable diseases and cardiovascular risk, detect risk factors, manage chronic patients, and provide medical advice and education. The results of such preventive screening (for 2014) are evident in the number of newly-diagnosed patients - during the 97 spirometries performed, 8 new COPD patients were diagnosed; the 195 conducted preventive screenings for chronic non-communicable diseases resulted in 14 newly-diagnosed type 2 diabetes patients and 13 patients with arterial hypertension. The presented data is the result of the work of a nurse practitioner who is currently working in two model practices, that is for two family physicians. Considering the fact that there were 436 model practices active in Slovenia in December 2014, one can imagine the approximate "profit" of such a work method, which proves the purpose and importance of working in such a broad team of model practices in Slovenia.

The purpose of this paper is to present the project of model practices, the role of a nurse practitioner in managing and treating patients in model practices and some of the results obtained so far by the new work method, which, generally speaking, confirm the positive effects of the complex treatment of patients provided by model practices.

P-0608**Evaluation of quality of life in people without chronic illness living in a district of Istanbul**

Sedat Ay¹, Asiye Sezer², Okcan Basat¹, Dilek Toprak²

¹Department of Family Medicine, Gaziosmanpaşa Taksim Training and Research Hospital, Istanbul, Turkey

²Department of Family Medicine, Şişli Hamidiye Etfal Training and Research Hospital, Istanbul, Turkey

BACKGROUND and AIM: In this study, we aimed to investigate the quality of life in people without known chronic illness living in a district of Istanbul.

METHOD: 336 subjects who are between 18 to 65 years and without chronic illness admitted to Gaziosmanpaşa Taksim Training and Research Hospital Family Medicine outpatient clinic between August to November 2014 were included in the study. A questionnaire form including the sociodemographic features and the Turkish validated short-form of the quality of life questionnaire version (WHOQOL-BREF TR) developed by WHO was performed. For statistical analysis frequency, chi-square and t-test were performed.

RESULTS: Our study was carried out on a total of 336 subjects, of which 136 were male and 200 were female. Mean scores of the physical, psychological, social and environment domains were 16.8, 15.8, 15.5 and 14.1 respectively. Males had higher Quality of Life scores than female participants, however this difference was statistically non-significant. Social domain scores were higher in males than females ($p < 0.05$), otherwise no significant difference was observed in other domain scores between male and female participants. Subsequent analyses showed that Quality of Life domain scores were not affected by age, literacy, marital status and alcohol & tobacco consumption.

CONCLUSIONS: Family physicians have the advantage in primary care patients with biopsychosocial approach with continuous care, therefore evaluating the quality of life must be one of family physicians' primary concerns.

Keywords: quality of life, no chronic illness, urban district

P-0609**Effect of Body Mass Index on the Quality of Life**

Asiye Sezer¹, Sedat Ay², Okcan Basat², Dilek Toprak¹

¹Department of Family Medicine, Şişli Hamidiye Etfal Training and Research Hospital, Istanbul, Turkey

²Department of Family Medicine, Gaziosmanpaşa Taksim Training and Research Hospital, Istanbul, Turkey

BACKGROUND AND AIM: Obesity prevalence is rapidly increasing all over the world as well as our country. Nowadays it is considered as a chronic disease resulting in many serious health problems and a reduced health-related quality of life. We aimed to investigate the relationship between body mass index and quality of life.

METHOD: 18-65 years and without chronic illness 336 people Taksim GOP Hospital Family Medicine outpatient clinic with any complaint between August 2014- November 2014 were included in the study. After body weight and height were measured, a questionnaire including the sociodemographic features and the Turkish short-form of the quality of life questionnaire version (WHOQOL-BREF TR) developed by WHO was performed. For statistical analysis frequency, Chi-square and t-test were used.

RESULTS: Our study was carried out on a total of 336 patients of which 136 were male and 200 were female. Body mass index distribution of participants in our study, 3.3% low weight (BMI <18), 44.0% normal (BMI: 18-24), 34.2% overweight (BMI: 25-29), 18.5% obese. In our study, by the BMI distribution there was no significant difference in mental, social, physical and environmental area scores. There were no significant differences in scores of mental, social, physical area at waist circumferences under and above 80 cm in women. Environmental area scores were significantly higher in above 80 cm than under 80 cm ($p < 0.05$). There were no significant differences in scores of mental, social, physical, environmental area at waist circumferences under and above 102 cm in men.

CONCLUSIONS: We detected that quality of life is affected by gender, alcohol use, waist circumference but not affected by age, BMI, education level, marital status, tobacco use. Family physicians, with biopsychosocial approach and continuous care, have a key role in prevention and treatment of obesity and subsequent effects on quality of life.

Prevention of running-related injuries in primary care

Mariana Fonseca¹, Mafalda Gonçalves¹, Isabel Melo¹, Sara Miranda³, Andreia Pinto²

¹Unidade de Saúde Familiar de Anta, ACES Grande Porto VIII

²Unidade de Saúde Familiar de São Miguel, ACES Grande Porto VIII

³Unidade de Saúde Familiar de Espinho, ACES Grande Porto VIII

Background and AIM:

Running in the adult population is one of the most popular physical activities around the world and the number of runners and running events has increased steadily in the last few years.

Although running is an effective way to achieve many health benefits, it is associated with a high risk of injury, diminishing pleasure in exercise and leading to a temporary discontinuation of running, increased costs and absence from work.

The aim of this review was to present an overview of the most common running-related injuries, risk factors and prevention strategies.

METHOD:

A review was performed for papers published between January 2005 to March 2015, in Portuguese/English, in the medical databases Medline/Pubmed and Cochrane Library, using MeSh terms “running” “injuries” “prevention” and “risk factors”.

RESULTS:

Acute running injuries are rare, consisting mainly of muscle injuries, sprain, or skin lesions. More than 80% of the complaints are due to overuse injuries, mainly affecting the leg, the ankle, the hip/pelvis/groin and the lower back. Risk factors for running injuries can be clustered into three areas: personal factors (age, sex, height, weight); running/training factors (running intensity, distance, running shoes, hip muscle weakness), and health/lifestyle related factors (smoking, comorbidity and previous injuries). There is evidence that insoles, the use of more than one pair of shoes, external supports and training programs with different components (mileage and rest, warm-up, footwear, nutrition and recovery, supplemental strength training) are effective to prevent running-related injuries.

CONCLUSIONS:

Frequency of running injuries tends to increase in a society awakening to the importance of engaging an active lifestyle. Family Physicians, as health managers, have the opportunity to first identify recreational runners and in an actively manner question, educate and guide healthy men and women that might not have any other contact with health professionals.

Keywords: Running, Injuries, Prevention, Risk factors

Incidence of Leg Running-Related Injuries

Main risk factors for RRI and respective preventive attitudes

Risk Factor	Evidence	Prevention
	Personal Factors	

Gender	No association found (1, 2)	
Age	Limited evidence (1, 2)	
Body Mass Index	No evidence (1) Evidence in the subpopulation of individuals with low weekly volume and with previous injury (3)	
Cavus Feet	Moderate evidence (4) Inconsistent results (2)	Orthotics use (4)
Leg Length Inequality	Weak evidence (4)	Heel lifts on the shorter leg (5)
	Running and Training Factors	
Duration	Weak evidence (6)	Run for 15-30 minutes a day (5)
Surface	Limited evidence (1, 2) Evidence of running on asphalt (hard) surfaces (5)	Variation in training surfaces (2,5) Optimal running surface should be smooth, resilient, flat and even and fairly soft (like grass or treadmill) (2,5)
Mileage	Limited evidence (1) Evidence of running greater than 40 miles (64 km) weekly in men (2, 4, 6) Unclear (3)	Limit total mileage to 65 km per week (2)
Orthotic/Insert	Moderate evidence (1)	Might lessen risk of stress fracture and symptoms of cavus feet (4)
Shoes	Limited evidence (1) Evidence when exceed 700 miles (5) Weak evidence (2)	Comfortable and well suited to the foot's shape (2) Good shock absorption (2) Replace shoe once it is worn out (2)
Stretching	Weak evidence (2, 4, 5)	After running, complementary to warm-up and strength training (2, 4, 5)
	Health and Life Factors	
Previous Injuries	Strong evidence (1, 2, 5, 6, 7)	Rehabilitation program (5) Gradual increase in training (5)

P-0611

Do I need malaria prophylaxis (last-minute travelers)

Paola Lievano, David Idoipe, Alvaro Irigoyen, Miguel Lopez Del Pueyo, Sara Lainez, Carlota Canet, Oscar Zepeda, Jesus Maria Tenias, Belen Gay, Cristina Marco, Laura Urieta, M^a Nieves Lozano, Raquel Martinez, Maria Barba, Amparo Cantin, Jose Antonio Ibañez, Miguel Rivas
Department of Community & Family Medicine. Sector III. Hospital Clínico Universitario Lozano Blesa, Zaragoza, Spain.

Background & AIM:

Most tourists who develop malaria do not adhere to an effective chemoprophylactic drug regimen not consulted before traveling (visiting friends and relative) and frequently fail to use personal protection actions for mosquito bite prevention.

It has been seen an increase number of consultations on the days before travelling and it is necessary our fast recommendation and accurate intervention.

METHOD:

Review available information of tropical medicine tools in primary care consultation.

RESULTS:

An interactive malaria map recommendations of chemoprophylaxis for specific destination according to the level of risk are available in the Spanish Ministry of Health website. Individual programs should be reviewed to determine the appropriate approach to chemoprophylaxis. More resources are available at the CDC website and the WHO provides useful online information including maps and malaria data.

Primary care intervention key objectives:

- Determine the risk of the area visited by the interactive malaria map website.
- Choose antimalarial drugs and prophylaxis protocols and considering an individual risk assessment, taking into account destination country, detailed itinerary, including specific cities, types of accommodation, season, and type of travel.
- Conditions such as pregnancy or the presence of antimalarial drug resistance at the destination may modify the risk assessment.

CONCLUSIONS:

Despite last minute consultations we can make an appropriate intervention. Travelers to malaria zones should understand that their planned itinerary puts them at risk for malaria, a serious infection that can be fatal. Prevention actions include avoiding mosquito bites and uses correctly an antimalarial chemoprophylaxis. Travelers should also know that no chemoprophylaxis regimen guarantees complete protection and that a fever during or after travel is a medical emergency requiring urgent medical attention.

Keywords: Malaria prophylaxis, last-minute travelers, antimalarial drug

Assessment and management of the nutritional status of the adult population in the West of Ireland GP practice

Malgorzata Wawrzynek¹, Wojciech Wawrzynek²

¹Castle Street Surgery, Roscommon

²The Medical Centre, St.Coman's Park, Roscommon

Background

Obesity is a frequently unrecognised prevalent condition, leading to several chronic illnesses. Its management is often unsatisfactory, as its causes are multi-factorial and difficult to rectify.

Aim

To explore the prevalence of overweight/obese patients in the West of Ireland, its recognition by patients and doctors, as well as to explore the ways patients and doctors are managing excessive weight with identification of barriers to obesity management in the General Practice.

Method

Adult patients attending for their GP appointments in Roscommon were asked to fill in a questionnaire in relation to their weight, then their weight, height and BMI were checked by the GP during the consultation. All GPs working in the surgery were interviewed to explore the present obesity management and barriers to it.

Results

112 adult patients participated in the survey. 58% of them were either overweight or obese, although only 45% of patients suspected to be of excessive weight. Minority of patients (41%) were of a healthy BMI. Doctors were monitoring patients' weight less frequently than they believed (62%) and were often reluctant to discuss the weight although more than 90% of patients were happy for weight discussion even if not directly related to the purpose of the consultation. The main barriers to obesity management identified by doctors were: limited time, inadequate obesity counselling training, fear of harming doctor-patient relationship, lack of access to multidisciplinary support team, especially psychology.

Conclusions

Although 75% of patients actively manage their weight, only half of them combines increased physical activity with diet modifications. Patients in general are more open to discuss weight than doctors are. Routine, frequent weight checks will help to diagnose overweight/obese patients. Open discussion of the illness and structured follow up, based on an established, honest doctor-patient relationship and continuity of care facilitates change and successful weight management.

Evidence-based information on screening for people with a positive family history of colorectal cancer - quality vs. time constraints in a cross-sectional study

Jasper Plath¹, Insa Koné², Anne Dahlhaus¹, Maja Taubenroth², Sylvia Schulz Rothe², Sandra Rauck², Andrea Siebenhofer³

¹Institute of General Practice, Goethe University Frankfurt, Frankfurt am Main, Germany; German Cancer Research Center (DKFZ), Heidelberg, Germany; German Cancer Consortium (DKTK), Heidelberg, Germany

²Institute of General Practice, Goethe University Frankfurt, Frankfurt am Main

³Institute for General Practice and Health Services Research, Medical University of Graz, Graz, Austria; Institute of General Practice, Goethe University Frankfurt, Frankfurt am Main, Germany; German Cancer Research Center (DKFZ), Heidelberg, Germany; German Cancer Consortium (DKTK), Heidelberg, Germany

Background

The primary aim of the cross-sectional study "FRIDA.Frankfurt" is to detect individuals aged 40-54 years with a positive family history of colorectal cancer (CRC) in a general practice setting. Approximately 875 affected patients are expected to require advice from participating general practitioners (GP) on increased risk and prevention strategies. For this purpose we developed an evidence-based decision aid on screening for persons with affected 1st degree relatives.

Methods

Information for people with a positive family history of CRC taken from a systematic review published in 2013 (search date -2011; Oxman/Guyatt=7) was added to an existing decision aid for the general population. We further performed a systematic update search on the risk of developing CRC (search date 2011-2014, PubMed/CDSR/DARE/CENTRAL), and checked whether information on the usefulness of the described screening-methods from the existing decision aid was transferable to people with a positive family history of CRC. Finally, we piloted the new brochure in two focus-groups.

Results

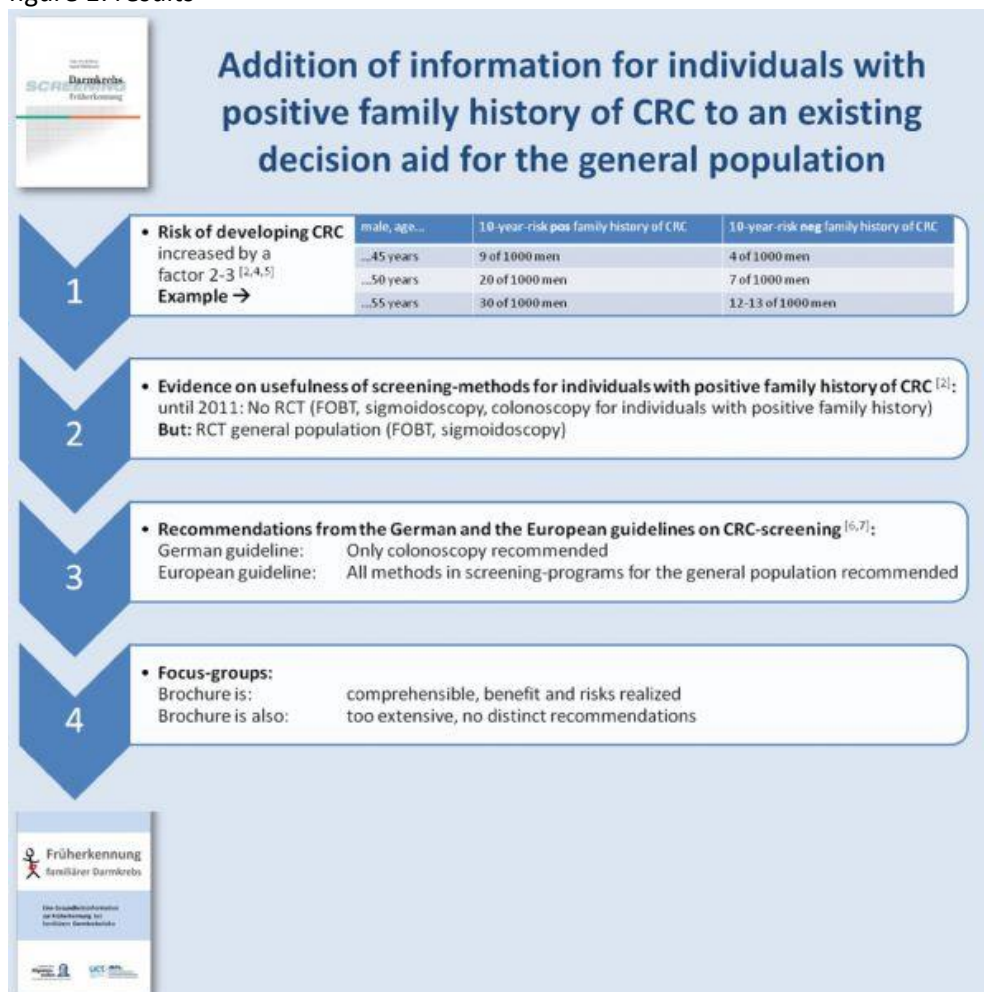

The brochure mainly contains information on the specific risk of developing CRC. Besides the systematic review, we included 1 relevant publication identified during the update search. The risk of developing CRC in the defined age group increases by a factor of 2.7 in case of a family predisposition. The results are shown as natural frequencies. Further contents of the brochure are information on the usefulness of screening-methods and recommendations from guidelines on CRC-screening. Results from the two focus-groups led to minor changes in the layout.

Discussion

On the basis of an existing decision aid, a systematic review and an update search, we developed a high quality brochure for our study within a limited time frame. Profiting from existing trusting relationships between GPs and patients, we expect the distribution of the brochure to result in an increase in the number of study-participants making informed decisions.

Tobacco Control: Building integrative approaches on tobacco use and smoke cessation in Primary Care – example of a Portuguese Healthcare Unit

Ana Sofia Pena, Ana Sofia Inácio, Jacinta Regente, Ana Paula Cardoso, Mariana Anete Mira, Susana Cordeiro Rita
USF Samora Correia, ACES Estuário do Tejo, ARSLVT, Portugal

BACKGROUND:

Tobacco use is the major cause of preventable disease and death and represents a huge burden. The health interventions for tobacco control are effective and efficient. In its latest National Health Plan, Portugal defined tobacco use as a priority health problem and established the main action axis for smoke control.

In our primary healthcare unit, tobacco use in our population was understudied when compared with the national prevalence of tobacco use.

METHODS:

In June 2013, our primary healthcare unit professionals designed an action plan to systematically map the reality of tobacco use in our patient population, so that tailored strategies could be designed and developed to control this health problem.

OUTCOMES:

In 6 months (till December 2013), the number of identified smokers raised about 9,7% compared to the initial value. The plan also allowed a demographic characterization of smokers, enabling us to design appropriate interventions in the future. The whole health team became more aware and motivated to manage this health problem in a daily basis and decided to enlarge the action plan for 2014.

In 2014 the team continued to systematically mapping tobacco use in the unit population and stepped forward with an intervention strategy, by proposing an intensive smoke cessation consultation following specific technical requirements (including skilled team members and specific measures to monitor practice) which was approved and has started in August 2014.

Till December 2014 the number of identified smokers raised about 21% and 56 smoke cessation consultations were performed, assisting 23 patients.

CONCLUSION:

It was possible to improve knowledge about tobacco use in our population and to develop intervention strategies, such as community interventions and a smoke cessation consultation. Specific evaluation indexes were defined and will be available for disclosure by August 2015, when this consultation completes one year of existence.

Alcoholism orientation protocol in Primary Health Care

Teresa Pereira Martins¹, Helena Ferreira², Maria João Abreu³

¹USF Novos Rumos - ACES Alto Ave, Portugal

²USF Uarcos - ULS Alto Minho, Portugal

³USF Duovida - ACES Alto Ave, Portugal

BACKGROUND & AIM: All over the world, alcohol is a major public health problem, with a total of 5.9% of deaths caused by alcohol consumption. Recent data from the World Health Organization, revealed Portugal as one of the countries with the highest annual consumption of alcohol: 12.9 liters of pure alcohol per adult. With the alcoholism being a chronic and progressive disease, affecting physical and mental health, and with marked social impact, the aim of this protocol is to unify the approach and orientation of this psychiatric illness in Primary Care.

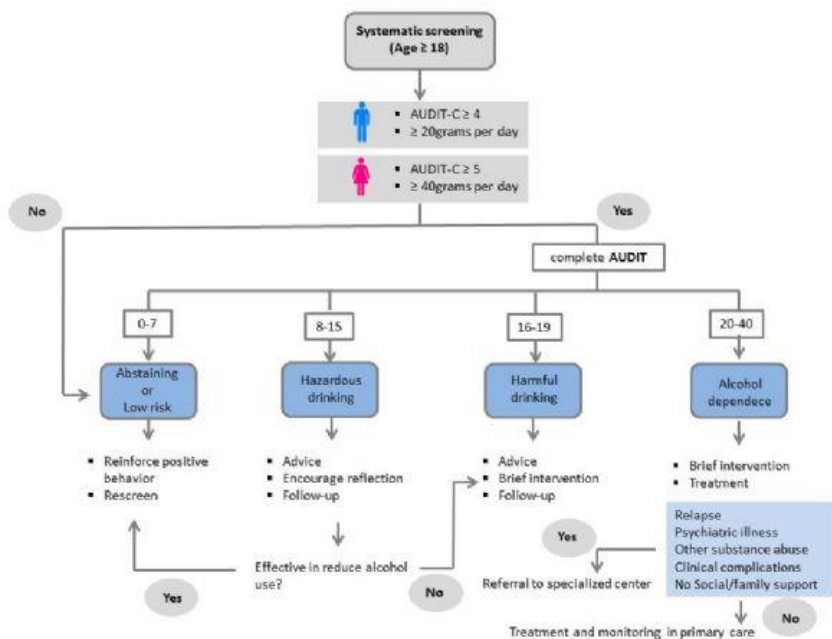

METHOD: Articles research in several databases using the MeSH terms alcoholism and Primary Health Care. The research was limited to the last five years and to articles written in English, Portuguese and Spanish.

RESULTS: Given the high prevalence of use and abuse of alcohol, the family physician, as a professional with continuous follow up of his patients, has diverse opportunities for screening unhealthy drinking. In the presence of alcohol consumption, the amount and dependence of the same should be established, followed by consumption stratification. Whenever pertinent, patient perspective of his consumption and motivation for change should be known. A careful clinical history, physical examination and additional diagnostic tests, allows the proper orientation of the patient in Primary or Secondary Care. Beyond screening and initial approach, the alcoholic dependence treatment includes detoxification and withdrawal phases, with a close follow up from health professionals.

CONCLUSIONS: Several studies have shown that screening and brief intervention in Primary Health Care leads to a reduction of harmful alcohol consumption. This performance may lead to a start point for treatment of alcoholic dependence and consequent or associated diseases.

"Phytotherapy and its Place in Alternative Medicine"

Özlem Özer, Halime Pınar Demiröz, Esin Oğuz, Yasemin Nur Makas, Zafer Erdin Demirbaş, Kenan Taştan
Atatürk University, Medical Faculty, the Department of Family Medicine, Atatürk University, Research and
Application Center for Methods of Acupuncture and Complementary Medicine, Erzurum

INTRODUCTION: Phytotherapy is an alternative treatment method that can be described as a treatment approach using plants. According to the World Health Organization, Alternative Medicine is a set of skills, knowledge and practices based on theory, belief and experience specific to different cultures employed to maintain good health as well as protection from physical and mental illnesses, and the diagnose and improvement or treatment of them.

BACKGROUND: The first written document on the therapeutic use of plants dates back to 3000 BC. Civilizations such as Sumer, Assyria, and Akkad in Mesopotamia region are known to have utilized herbal medicine. There are important works of Ibn Sina and Al Gafini on herbal medicine in Islamic Civilization. Ibn Sina wrote about medicinal plants and their use comprehensively in his book called "El KanunFi'tTıbb".

Medical Uses of Phytotherapy:

- Dermatological diseases (allergies, skin rashes, eczema, dermatitis)
- Vascular diseases
- Migraine and similar psychosomatic headaches
- Blood pressure problems (hypertension, hypotension)
- Liver and gall bladder diseases (hepatitis, gallstone)
- Diabetes mellitus
- Rheumatic diseases
- Respiratory diseases

The statement of WHO that 80 % of people believe this natural treatment is a good indicator of this popularity. 600 million people a year in the USA consult alternative medicine specialists to get therapy support and 60 % of the population over 18 years of age use a product of herbal medicine at least once a year. This rate reaches 70 % in Japan.

CONCLUSION: Phytotherapy is widely used all over the world and in our country. However, it can lead to many health problems if used incorrectly. Therefore, the use of phytotherapy by right health care practitioners and the administration of training in this field will be a significant gain in terms of both preventive and therapeutic medicine.

World Diabetes Day and World Food Day – General practitioners providing health information and screening in a local science museum

Gonçalo Envia, Inês Lima, Rita Brochado, António Branco, Madalena Rapazote, Hugo Dias
USF Monte da Lua, Várzea de Sintra, Portugal

BACKGROUND AND AIM: Cardiovascular and metabolic conditions such as obesity, diabetes and hypertension are known to be important causes of morbidity and mortality, particularly in developed countries. It is well established that a healthy lifestyle, namely through a balanced diet and physical exercise, is not only the best preventive measure but also the first step in the treatment of such conditions. Family physicians have the responsibility to promote healthy behaviours, either with individual patients or through their unique connection to the community. For that purpose, we developed two activities in a science museum near our primary care centre, to provide information in a fun interactive way and screen the population for cardiovascular risk factors.

METHOD: The first activity (at the World Diabetes Day) aimed to clarify some aspects of the disease, its

prevention and treatment. At the end, attending people were offered the possibility of cardiovascular screening (measurement of blood pressure, blood glucose, body mass index and advice regarding diet, exercise and smoking cessation). The second activity (at the World Food Day) was intended for local students (6th graders) in order to stimulate better lifestyle choices regarding diet and exercise. This activity included a screening for obesity and malnutrition and personal advice.

RESULTS: Both activities were successful, with dozens of participants and a general sense of satisfaction. When cardiovascular risk factors or conditions were identified, people were advised to seek their doctors.

CONCLUSIONS: Family physicians have the unique opportunity to interact with the community. Activities such as these contribute to promote common wellbeing and health. It is desirable that this partnership of the primary care centre with the science museum continues, with new activities in the future.

Do our teenagers want to quit smoking?

Ruth Muñoz Maya¹, Álvaro Alonso Flores¹, Carmen María Jiménez Herrera²

¹CS Don Paulino García Donas, Alcalá de Guadaíra. AGS Sevilla-Sur, Andalusia, Spain

²CS Ntra. Sra. de la Oliva, Alcalá de Guadaíra. AGS Sevilla-Sur, Andalusia, Spain

Background: Smoking is nowadays the first preventable cause of death worldwide and contributes greatly to the increasing number of non-transmissible diseases. It's been estimated that nearly six million people die every year because of tobacco smoking related conditions. It also entails a major cost to the sanitary system.

Studies launched in 2012 in our area show that nearly 50% of smokers between 16 and 65 years wanted to quit smoking; 30% of individuals from 16 to 24 years smoked every day. Tobacco consumption is consolidated in secondary education students.

The age of starting smoking is not clearly established in our town, but alcohol drinking begins at about 13 years-old. We presume alcohol and tobacco consumption starting are alike in teenagers.

Andalusian Health Service offers a programme for helping to cease tobacco smoking. Since we've been performing this programme, no adolescent between 12 and 16 years has come to our office asking for help.

Aim: To bring out the reasons why teenagers between 12 and 16 years old in our town don't ask for help to quit smoking

Method: We provided a questionnaire to the pupils in the high school next to our center asking about smoking and information about the ceasing smoking programme we display. We can measure the incidence and prevalence of smoking habit among our young population and the reasons leading them not to ask for help

Conclusions: At this moment we are still collecting data that will be shown at the conference. We find this study interesting because knowing why and how often adolescents smoke and why they don't are motivated to come to our ceasing smoking programme will help us to improve both the service we are providing at our consultation and the health promotion campaigns we display at high schools.

Keywords: adolescent, smoking, smoking cessation, health education

Active ageing is not a new concept

Ieda De Paula¹, Vanessa Carvalho¹, Leonor Troni², Inês Abreu Mendes³, Pedro Alves³, Mileta Gomes⁴

¹USF Cynthia, ACES Sintra, Portugal

²UCSP Torres Vedras- extensão Silveira, ACES Oeste, Portugal

³USF D.Sancho I, ACES Lezíria, Portugal

⁴UCSP Almeirim, ACES Lezíria, Portugal

The World Health Organization (WHO) defines active ageing as “the process of optimizing opportunities for health, participation, life-long learning and security in order to enhance quality of life as individuals age”.

Active ageing is a topic deserving an increasing attention in scientific and policy discussions on ageing.

This paper reflects the stance of the WHO on this subject and addresses the challenge of rapid ageing population, especially in developing countries.

Our research was done in databases of Evidence Based Medicine, using the following key words: active ageing, elderly and primary care. It was limited to articles in English, Portuguese and Spanish, published from 2010 until February 2015.

Active Aging promotes elderly living as fully as possible in all areas of life—physical, social, spiritual, emotional, intellectual, vocational and environmental.

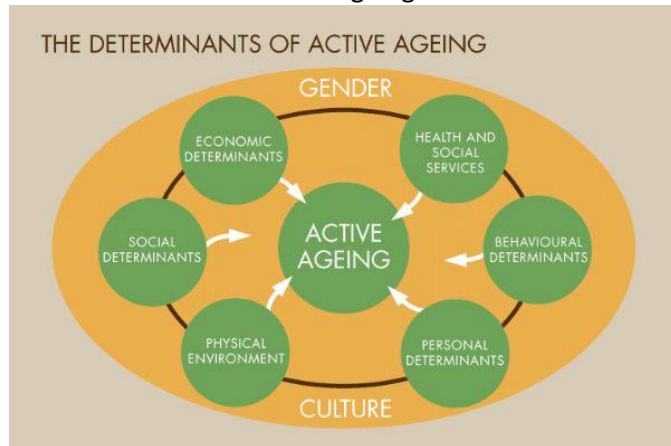

The concept of active ageing is based on three pillars mentioned in the definition: participation, health, and security. The proposed model encompasses six groups of determinants (each one including several aspects): social and health, behavioral, personal, physical, social and economic.

As people age, their quality of life is largely determined by their ability to maintain autonomy and independence and healthy life expectancy.

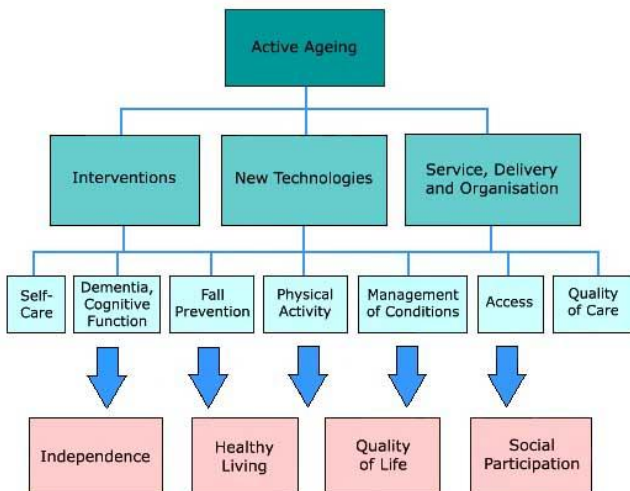

Healthy elder people are a resource to their communities and families. It is important to get involved in groups according individual preferences. They can put their experience, their abilities and their enthusiasm in the volunteering associations or cultural groups. Benefits are double for the society and for the elder people. Active ageing appears as an outcome of different determinants that should allow us to identify particular profiles that are more at risk or, on the other hand, more inclined to age actively.

Comprehensive treatment of patients with Diabetes mellitus type 2 in model practice

Katerina Bubnič Sotošek, Andriana Sotirov, Antonija Poplas Susič

Community Health Centre Ljubljana, Ljubljana, Slovenia

Background, AIM: Chronic hyperglycemia presents in patients with Diabetes mellitus type 2 (DM2) is cause for chronic complications. Proper and long term joint cooperation between the medical team and patient improves outcome of treatment. Efficient treatment requires defined quality criteria. The aim is to analyze and search for improvements in treatment of patients with DM2.

METHODS: The study consisted of 150 patients with DM2 from model practice, treated according to the guidelines and quality criteria: examination of feet and fundus, regularity of blood pressure and laboratory tests: glucose level, HbA1C, lipid profile, glomerular filtration rate and proteinuria/albuminuria.

RESULTS: The 98.56% of patients had annually measured glucose level and HbA1C. Goal values achieved 61.54% of them. For 90.77% of patients laboratory tests were performed, while 36.92% had goal value for LDL cholesterol. Unfortunately, only 35.38% of patients had feet examination. On the other hand, 56.92% of patients had fundus examination. All patients, however, had measured blood pressure, with 49.23% of them having goal values.

CONCLUSIONS: Results show that medical team cares for patients adequately in sense of performed measurements (>90%). The goal values were achieved in less than 50% of all cases. Feet examination had 35% of patients, where main responsibilities have graduate and patronage nurse. To achieve goal values easier patient cooperation is mandatory. For this purpose additional individual education and training would be reasonable. Improvements in treatment should also incorporate regular fundus examination, care for older less mobile patients having difficulties coming to model practice. During treatment in model practice patient should acknowledge essential facts about the disease, accept it as part of everyday life, gain skills and knowledge for its control. Ultimately, the goal is to ensure high quality of life of patients with DM2 regardless of age and controlling the disease and its chronic complications.

Assessment of a Sexually Transmitted Infections circuit in an urban primary health care centre

David García Hernández, Santiago Lancho Lancho, María Cecilia Casano Carnicer, Kristýna Klevarová, Agnès Salvador Mateo, Laura Eroles Mallolas, Judit Martínez Téllez, Aina Piera Salmerón, Natàlia Subirats Duran, Maria Inês Dos Reis M. Van Zelst, Ana Romagosa Pérez Portabella, Laura Romera Liébana
EAP Raval Nord Primary Health Care Centre, ICS, Barcelona, Spain

Background and AIMS: Sexually Transmitted Infections (STIs) represent a European public health problem, specially in the last 15 years. Hereby, a STIs circuit was accomplished in an urban primary health care centre (PHCC) in order to: 1) Improve patient accessibility; 2) Provide a global STI care (including diagnosis, notification, treatment, contacts tracing, STIs screening, follow up, prevention and counselling); 3) Increase Primary Care professionals' training and 4) Enhance collaboration between care levels. In addition, patient and doctor satisfaction with this circuit was analysed using questionnaires.

METHOD: The project was initiated in April 2014 by a Family Doctor (FD) with special interest in STIs (FDSISTI), who was previously trained for one year. The FDSISTI performs (with a FD trainee) a weekly STIs consultation in the PHCC. All patients and contacts receive treatment (if necessary), STIs screening, follow up and counselling; and they are referred to other specialists if needed. STIs briefings are held bimonthly for the PHCC professionals. The satisfaction survey consisted of 4 questions to the patients and 3 questions to the referring FDs, with possible score going from 1 (dissatisfied) to 5 (highly satisfied).

RESULTS: Until December 2014, 288 consultations of 93 different patients were performed (82% men, 51% foreigners, average age 34.78). The main diagnoses were: condyloma (50), nonspecific urethritis (10), herpes (10), chlamydia (8), gonorrhoea (8), syphilis (7). The main treatment was cryotherapy. Regarding patient satisfaction, the mean score of the answers was as follows: information given (4.74/5), care provided by the FDSISTI (4.81), treatment-result of the problem (4.41) and the circuit in general (4.43). In terms of FD satisfaction, the mean score of the responses was: learning about STI (4.75/5) and circuit usefulness (4.82).

CONCLUSIONS: Patient and care providers' satisfaction was very high. The circuit can improve accessibility, FDs knowledge and coordination between specialists.

Behavior risk in a teenage population of a Lisbon Primary Care Unit

Diana Sofia Duarte¹, Andrea Pova Antunes¹, Catarina Ameixa Morgado¹, Inês Vinga Martins¹, Miguel Marques Ferreira¹, Avelina Pereira Moniz²

¹Family Physician resident, USF Tejo, Lisbon, Portugal

²Family Physician, USF Tejo, Lisbon, Portugal

Introduction

Adolescence, between 10 and 18 years-old (DGS), is characterised by physical, psychological and social changes. The search for a wider autonomy and socialisation may lead to risk behaviours.

The family doctor has a privileged role in the promotion of healthy life styles.

The scarce search for health care services motivated the USF Tejo medical team to implement a session.

Objectives

To know the risk behaviours (alcohol, cigarette smoking, illicit drugs), sexual activity and contraceptive methods used by the teenagers.

Methodology

Study - descriptive and transversal

Population – teenagers between 15 and 18 years-old

Inclusion criteria – teenagers between 15 and 18 years-old affiliated in the USF Tejo during last year

Variables – age, alcohol, cigarette and illicit drugs consumption, age of beginning of sexual activity and contraceptive method used

Methods – Elucidation sessions about risk behaviours

Data collection – fulfilment of an anonymous enquiry

Results

Teenager population: 431 individuals (212 female and 219 male).

The feminine sex was represented by 54 teenagers: age average 15,7 years-old.

11,1% smoke, 48,1% admitted to drink alcohol, 14,8% have experimented illicit drugs, 14,8% have already started sexual life and 75% used condom in the first relation.

The masculine sex had 28 participants with an average age of 16.5 years-old.

7% are smokers, 18% have experimented illicit drugs, 18,5% have already started sexual life, 87,5% mentioned the use of condom in the first relation.

Discussion and conclusions

Information and awareness are protection factors near the adolescent population. The family doctor has the opportunity to act precociously. Teenagers are difficult to convoke. This kind of actions allows the empowerment of this group and improves the visibility of the health services.

Understanding the life style of this sub-population is important for planning the services and to increase the access to health care.

Evaluating potential foods as a cause of foodborne disease

Nikolaos Prassas¹, Panagiota Tsiatsiou¹, Emmanouil Velonakis³, Kassiani Mellou⁴, Konstantina Kontopoulou⁵, Alkiviadis Vatopoulos²

¹AHEPA University Hospital, Thessaloniki, Greece

²Department of Microbiology, National School of Public Health, Athens, Greece

³Central Public Health Laboratory, HCDCP, Athens, Greece

⁴Office Foodborne Diseases, HCDCP, Athens, Greece

⁵General Hospital of Thessaloniki, G. Gennimatas, Thessaloniki, Greece

BACKGROUND-AIM: In the light of current market conditions, the consumers' habits and the mass food production are changing rapidly, therefore, a vast number of consumers run the risk of foodborne diseases. Thus, the purpose of this study is twofold. First, it is aimed at examining the effect of preceded disease from food illness or not on the respondents' perception of the contagiousness of a disease through foods and second to identify which food might be a potential vehicle of foodborne disease by comparing the results of two groups (preceded or no infection).

METHOD: In order to accomplish the objectives of this study, a structured questionnaire was used. The data was collected by intercepting patients, companions and employees from AHEPA hospital and Health Center of Sohoh, Thessaloniki, during the period of 01/09/2014 to 28/02/2015 and yielded a usable sample of 401 completed questionnaires. The sample was comprised of 197 respondents without any previous foodborne illness and 204 respondents who had already suffered from a foodborne disease.

RESULTS: The study was conducted by pearson chi-square analysis. The analysis results indicated that significant differences between the two groups were found in all categories of foods, such as eggs ($\chi^2=18.775, sig.0.000$), milk ($\chi^2=42.159, sig.0.000$), vegetables ($\chi^2=17.480, sig.0.000$), seafood ($\chi^2=10.239, sig.0.001$), meat ($\chi^2=30.862, sig.0.000$), water ($\chi^2=33.919, sig.0.000$). The analysis indicated meat, seafood and eggs as the most dangerous kinds of food for an infection by respondents who had already been infected. Unlike meat (lower from the other group), water and milk were blamed for foodborne disease by the previously non-infected respondents.

CONCLUSIONS: The study shows that various foods prompt respondents to be careful with their daily food consumption. However, the differences between groups show that they have not received all the appropriate information on how to protect themselves by everyday food threats and judge subjectively the food categories.

Study Of Relationship Between Female Literacy And Health Status Of Families And Community Among The Female Patients of CHC Muradnagar

Piyush Jain

Community health centre (chc), Department of health and family welfare, Uttar Pradesh, India.

BACKGROUND:

Low female literacy have been shown to result in less healthy choices, riskier behavior, poor health of families and community, less self-management and more hospitalization. They significantly drain human and financial resources in the health system.

This paper explores the impact of female literacy on the general health status of the families in the community, their awareness about the various health issues and utilization of the health facilities present at their nearest health centre.

Aim

To Assess the relationship between the female literacy and health status of families in the community and to raise awareness about health and female literacy among the patients attending OPD of the hospital.

MATERIALS-METHODS:

A cross-sectional, questionnaire-based study was carried out and information was obtained about the general awareness of female patients about health, daily habits, utilization of health facilities, preventive health habits, status of child immunization, number of children, socio-economic status, access to health services, presence of sanitation facilities, employment outside the home and child care management.

RESULTS:

The results shows that relationship between the female literacy and health status of families and community is directly proportional. More the literate female is – better is the health status of her family and community. Study shows that more awareness about the health related issues and health facilities is found among the most literate group of the females. They are more aware about the use of health facilities, size of family, vaccination and other.

Low literacy leads to poorer overall health, misuse of medication or misunderstanding of health information, preventable uses of health services, including emergency care, avoidance of initial symptoms to seek medical help.

CONCLUSION:

Low literacy rate among the females are associated with riskier behavior, poorer health, less self-management and more hospitalization and costs. Thus, it is required to concentrate more on female literacy with the whole-of-society approach by working together to improve the literacy status and health of females in the community.

Escherichia coli lysates in recurrent urinary tract infection prevention – Evidence based review

José Silva Russo, Bruno António Covelo De Almeida, Ana Margarida Romão, Sara De Sousa Rocha
Unidade de Saúde Familiar Descobertas, Belém, Lisboa, Portugal

Background & AIM: Urinary tract infections (UTIs) are the second most common community acquired infection and E.coli is the agent responsible for 75% to 95% of cases. The most frequent UTI is acute cystitis, which affects mostly premenopausal women. About one quarter of patients with one UTI infection will be infected again. Recurrent UTI is defined by 2 episodes in 6 months or more than 3 episodes in 12 months. With the emergence of antimicrobial resistance to antibiotics and those being the first line treatment for UTIs it is necessary to find alternative solutions for recurrent UTIs. The use of prophylactic immunotherapy of Escherichia coli lysates can make an important contribution in reducing recurrences without interfering with resistance to antimicrobials. Our aim is to determine the scientific evidence about the effectiveness of therapy with bacterial lysates of E.coli in the prophylaxis of recurrent UTI in women.

METHODS: Literature research in the main databases using the following MeSH terms: UTI terms, Uro-vaxom and OM-89. We selected the articles that met the inclusion criteria. To assess the level of evidence and strength of recommendation, we used the Strength of Recommendation Taxonomy scale (SORT) of American Family Physician.

RESULTS: we obtained 33 articles from which we selected 5 that complied by the criteria set in METHODOLOGY: 2-meta-analyzes, 2-clinical trials and 1-standard clinical guidance. The clinical trials found a 34% reduction (level of evidence 1) in UTI recurrence in a 12 months follow-up. In the meta-analysis, there is a risk reduction of around 39%. The clinic orientation norm selected, by the European Association of Urology, recommends the use of bacterial lysates in recurrent UTI in women.

CONCLUSION: Treatment with lysates of E.coli is indicated in recurrent UTI prophylaxis in women (SORT B). The use of this therapy is safe with low incidence of clinically significant adverse reactions.

Health Diagnosis of Es Coll d'en Rabassa neighbourhood

Enrique Alvarez Porta¹, Catalina Isabel Bisbal Navarro¹, Pablo Alexander Rosario Dourthe¹, Atanasio Garcia Pineda¹, Sebastià March Llull², Rosa Duro Robles¹, Antonia Fe Pascual¹, Josep María Méndez Guillaumet¹

¹Es Coll d'en Rabassa / UBS Es Molinar Health Center. Palma de Mallorca. Spain.

²Research Technical Office of the Teaching Unit of Family and Community Medicine of Palma de Mallorca. Spain.

BACKGROUND: The Health District (ZBS) of Coll d'en Rabassa encompasses the neighbourhoods of Can Pere Antoni, El Molinar and Coll d'en Rabassa and is forming part of the district Playa de Palma (Palma de Mallorca).

OBJECTIVES:

- Principal: Analyze the health status of the population of the Coll d'en Rabassa ZBS.
- Secondary: 1) Gather social determinants and health information for this population. 2) Know the expectations in health of population and health professionals. 3) Identify actives in health in the ZBS.

METHODS:

- Design: quantitative and qualitative, cross-sectional, descriptive study.
- Population: Residents of Coll d'en Rabassa ZBS.
- Sampling: 6 representative informants of the population of the ZBS.
- Collection of information: quantitative information on health determinants and indicators are prompted to official institutions; semi-structured individual interviews were conducted in depth to reach saturation of information, selecting participants through subjective sampling by reasoned decision, with the help of key informants in the field. The interviews will be tape recorded and later transcribed. The content will be analyzed by everyone in the team.

RESULTS: Results of this study will be available in May 2015.

Conclusiones: Conclusions of this study will be available in May 2015.

Internet addiction- Only a theoretical problem?

Pedro Moreira Castro¹, Sofia Paulino², Ana Rocha³, André Lourenço³, Inês Macedo³

¹USF Modivas, ACeS Grande Porto IV, Vila do Conde, Portugal

²Serviço de Psiquiatria, Centro Hospitalar Lisboa Norte, Lisboa, Portugal

³USF Modivas, ACES Póvoa do Varzim, Vila do Conde - Portugal

BACKGROUND AND AIM: Given the widespread use of the Internet, researchers have begun to examine the personal and social consequences associated with excessive online involvement. We made a review of the published literature on Internet Addiction (IA) in young adults with the aim of defining the problem and the most effective therapeutic intervention.

METHOD: multiple database search (textbooks, guidance manuals, systematic reviews and articles published in scientific databases selected for their adequacy and scientific relevance).

RESULTS: Internet Addiction can be conceptualized as an inability to control one's use of the Internet. Although pathological gambling is currently the only confirmed behavioral addiction, Internet Gaming Disorder emerges for the first time in the DSM-5 appendix as an entity under study.

IA is not only positively correlated with psychopathology and psychiatric disorders but also has severe consequences in several bio-psychological areas of life such as loss of occupational and social functioning, sedentary lifestyle, weight gain, insomnia, interrupted sleep and decreased total sleep time, changes in circadian rhythm, social isolation and disruption of interpersonal relationships.

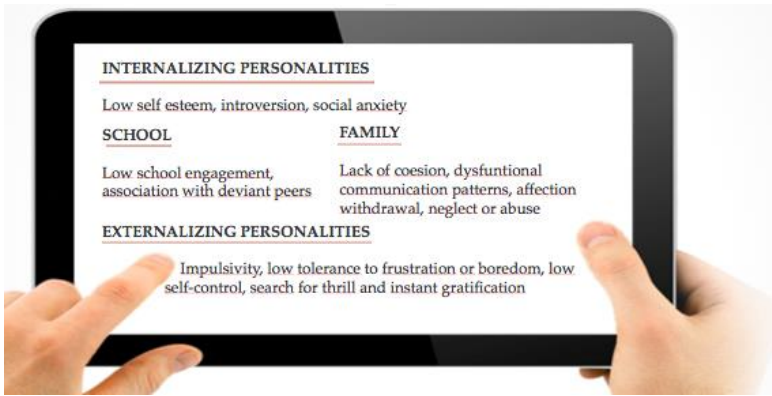

CONCLUSIONS: Health care services can and need to raise awareness of this entity and of the associated interventions. Family doctor is usually the first contact within the health care system so it's essential to know how to identify major risk factors and be able to recognize the issue earlier.

OM-89 for prevention of recurrent urinary tract infections: An evidence based review

Ana Margarida Pinho, Célia Gomes Silva, Ana Catarina Rodrigues

ACES Entre Douro e Vouga I Feira/Arouca, USF Famílias, Lourosa, Santa Maria da Feira, Portugal

Background & Aim

Recurrent urinary tract infections (UTIs) are very common in women and responsible for considerable morbidity and health care use.

Recurrent uncomplicated UTIs may be defined as 3 or more uncomplicated UTIs in 12 months.

In individuals with recurrent UTIs, low dose antibiotic prophylaxis for several months can be recommended.

Escherichia coli is the predominant uropathogen isolated in acute community-acquired uncomplicated UTIs. The increasing prevalence of this bacteria isolates that are resistance to antimicrobial agents has stimulated interest in nonantibiotic methods for the prevention of UTIs.

The aim is to review the available evidence on the efficacy of OM-89 in preventing recurrent uncomplicated UTIs.

Method

A search for clinical practice guidelines, meta-analysis, systematic reviews, evidence-based reviews and clinical trials published between January 2005 and March 2015, in English, Spanish and Portuguese was performed using

the MeSH terms: UTIs and OM-89. The Strength of Recommendation Taxonomy scale of the American Family Physician was used to assess the quality of the studies and the strength of the recommendation.

Results

Of the eleven articles found, only three fulfilled the inclusion criteria and were selected. These included one practice guideline, one meta-analysis, and one systematic review.

The practice guideline recommended OM-89 for immunoprophylaxis in female patients with recurrent uncomplicated UTIs. The meta-analysis and the systematic review are concordant and suggest that OM-89 seems to effectively decrease the recurrence of UTIs in adult women without associated comorbidities.

Conclusions

Evidence from available studies suggests that the oral immunostimulant OM-89 can be beneficial for preventing recurrent UTIs in women (Strength of Recommendation B).

However, this recommendation is limited by the heterogeneity of studies.

More studies are needed to establish safety and tolerability in other populations as well as the efficacy relative to antimicrobial prophylaxis and other nonantibiotic prophylaxis products.

Keywords: Urinary Tract Infection; OM-89; Vaccination.

Inclusion Criteria

P Population/patient	Adult female patients with recurrent uncomplicated UTIs
I Intervention/indicator	OM-89
C Comparator/control	Placebo or other prophylactic therapy
O Outcome	Prevention of recurrent uncomplicated UTIs

Pharmacological Treatment of Obesity and Excess Weight in Adult: A review

Sara Quelha, Bruno Morrão, João Dias, Rita Miranda
 USF Arca d'Água; ACeS Porto Oriental; Porto; Portugal

Background and AIM: Obesity and overweight are the most common nutritional disorder in Western society whose prevalence has increased globally. The General Practice (GP) deals daily with the consequences of this epidemic, the higher risk that this entails the development of major health complications. Thus, it is essential to act early and treat excessive weight gain. The aim of this study is to summarize the pharmacological therapy available for the treatment of obesity and overweight.

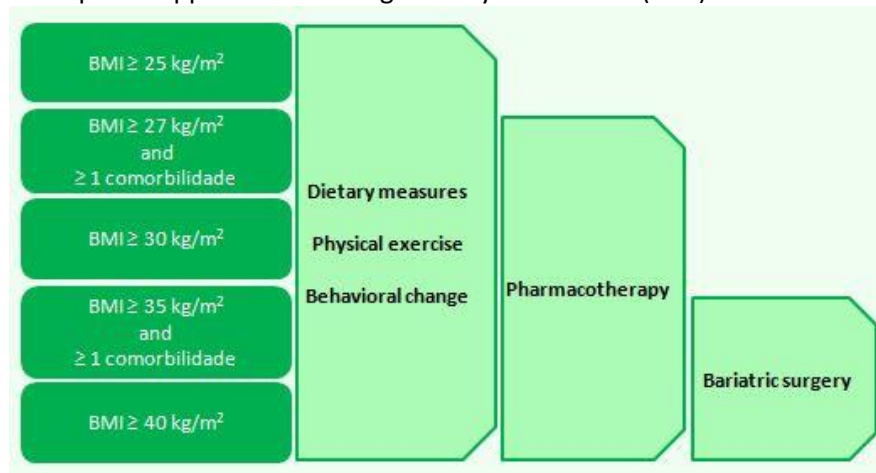

METHODS: Classic literature review, based on articles in the PubMed, referring to promoters of weight loss drugs.

RESULTS: The mainstay of treatment is lifestyle changes (diet and exercise) and behavior, which can be combined pharmacological and / or bariatric surgery. However, not always the diet and exercise are enough to reverse the underlying biological and psychological disruption. Currently there are eighteen drugs available to treat these diseases, all effective in weight loss, though minor is not associated with the above changes.

CONCLUSIONS: The anti-obesity drugs have been become an added therapeutic value, being only two approved and available in Portugal. Since this is a constantly evolving area, the launch of new drugs are perspective-in combating this disease.

Keywords: obesity, anti-obesity agents, drug therapy

Therapeutic approach according to Body Mass Index (BMI) and comorbidities

Pulmonary Lymphangitic Carcinomatosis due to Breast Cancer: A Case Report

Daniel Beirão Sousa, Sofia Marçalo, Maria Cândida Guedes

Unidade de Saúde Familiar S. Félix da Marinha, ARS Norte, Vila Nova de Gaia, Portugal / Family Medicine Center of S. Félix da Marinha

Background and AIM: Breast cancer remains the most lethal malignancy in women across the world. It is known to metastasize to the lung, liver, bone and brain. However, manifestation through lymphatic spread to the lungs is rare. In fact, Pulmonary Lymphangitic Carcinomatosis (PLC) accounts for only approximately 6 to 8% of all intra-thoracic metastatic disease. The occurrence of PLC is most common in lung cancer, followed by breast cancer and gastric cancer.

CASE: A 55-year-old women, with a breast carcinoma on 6th year remission, initially presented to our clinic with dry cough of one month duration, which became productive at the time of our examination. The patient reported no further relevant symptoms. A chest radiograph was requested and empiric and ambulatory antibiotic therapy was initiated to treat a suspected community acquired pneumonia. One month later, she appears with progressive dyspnea, weight loss and a single cervical adenopathy. Lymph node biopsy was inconclusive, but computerized tomography (CT) scan of thorax and abdomen revealed abnormalities in the right lung and PLC with pleural and pericardia effusion. The patient was immediately referred to an Oncological Hospital, where she went for further disease studies. About 3 weeks after our referral she was admitted for hospitalization due to a rapidly progressive dyspnea. She died of respiratory failure 7 days later.

CONCLUSION: PLC is a rare clinico-pathological entity, and its presentation can mimic several lung disorders. A high index of suspicion is required to diagnose this condition. To date, no effective strategies have been developed for PLC treatment and so, the prognosis remains extremely poor.

Keywords: pulmonary lymphangitic carcinomatosis, breast cancer, respiratory failure.

Evaluation of the alcoholic habits of a sample of the population of registered users in a primary health care unit

Catarina Bica, Lílíana Carvalho, Nuno Sena De Barros, Andreia Gonçalves, Ana Sofia Rua

USF Marquês de Marialva, Cantanhede, Portugal

BACKGROUND: Alcohol is the third leading cause of disease and premature death worldwide. In Europe, where alcohol consumption is highest, it's also the third leading risk factor for morbidity and mortality for various diseases, increase in crime rates, domestic violence and road accidents. A recently published study showed that

the prevalence of consumption at levels above the recommended can reach 34% and that 70% to 98% of cases are not identified.

AIM: To explore the drinking habits of a sample of the registered users in a primary care health unit, through the application of the AUDIT questionnaire.

METHOD: Observational, cross-sectional study with analytical intention. Convenience sample of users asked to fill an anonymous questionnaire, from 21/10/2014 to 11/07/2014, with a section on cardiovascular disease history, smoking habits and another with the AUDIT. Inclusion criteria: users with consultation, above 18 years old, literate (or illiterate if aided by a third party). The selected variables: age, education, profession, disease, CVD history and results of the AUDIT. Statistical analysis with Microsoft Office Excel 2010®.

RESULTS: Of the 482 questionnaires returned, 441 were considered valid. Of these, 35.1% were men. The average age was 50 years. In AUDIT, 98% had a score between 0 and 7; 8 users reported a score between 8 and 15 (harmful use); 2 users scored between 16 and 19 (risk drinking) and only 1 user earned a score between 20 and 40 (alcohol dependence).

CONCLUSION: We can conclude that the vast majority of users who responded to the survey have acceptable alcohol consumption, requiring only preventive education in this area. However, these results were unexpected, since it is a population living in a wine region, leaving the authors to wonder about the veracity of the statements and the reality of alcohol consumption in the population studied.

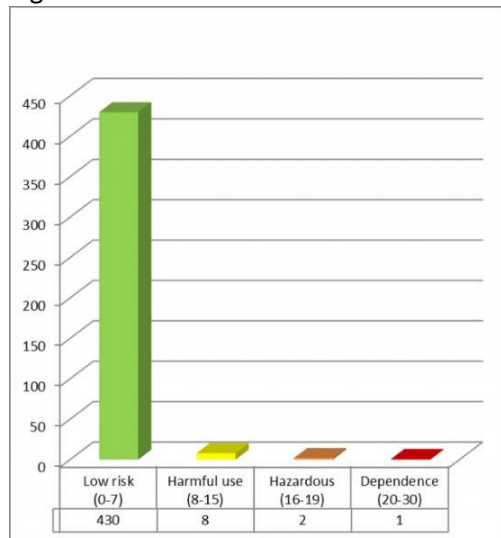

Keywords: alcoholic habits, AUDIT questionnaire, premature death

Initial compliance evaluation to Mediterranean diet of a population of a Primary Health Care Unit

Nuno Barros, Catarina Bica, Andreia Gonçalves, Sofia Rua, Luis Ribeiro

USF Marquês de Marialva, Cantanhede, Portugal

Background and Aim

The Mediterranean diet (MD), originated from countries in the Mediterranean basin, is characterized by a nutritional model that has been considered, by current evidence, as one of the healthiest, translating into a lower risk of mortality from cardiovascular disease (CVD), cancer and lower probability of dementia.

This study's main goal is to explore the dietary habits of a population of patients from a Primary Health Care Unit, regarding their level of adherence to this type of diet.

Method

Observational, cross-sectional study with analytical intention. Convenience sample of users asked to fill an anonymous questionnaire, The MEDAS (MD adherence screener) adapted, for a period of six days. Inclusion criteria: users with consultation, over 16 years old. We selected the variables Body Mass Index (BMI), waist circumference Height Ratio (WCHR), smoking habits and physical activity. Statistical analysis was made with Microsoft Office Excel 2010®.

Results

Out of the 80 questionnaires distributed, 43 were correctly filed. Of these, 39.5% were male. The mean age value was 48.84 years old (17-80). Regarding BMI and WCHR, the mean values were 29.15kg/m² (19.28-46.25) and 0.60 (0.39-0.83), respectively. Obesity was found in 39.54% of patients and 41.18% had BMI over 35; 11.63% smoke regularly, whereas 44.19% were former smokers. Only 24.1% claimed to practice exercise regularly.

The MEDAS Score had a high mean value of 9.07 (4-13), meaning a high adherence to the MD.

Conclusions

Despite the high level of adherence to the MD, the sample shows high prevalence of obesity and low levels of exercise. Because many previous studies support the role of the MD on lowering the risk of metabolic syndrome when associated with regular physical activity and no smoking habits, our study showed us that we need to focus on the encouragement of physical activity and smoking cessation programs.

Immunization Status of Young People Attending a Youth Clinic in Geneva, Switzerland

Anne Meynard¹, Lydia Markham Genequand², Emilien Jeannot³, Claire Anne Wyler Lazarevic⁵, Bernard Cerutti⁴, Françoise Narring¹

¹Unité Santé Jeunes, Division of General Pediatrics, Department of Pediatrics, University Hospitals, Geneva, Switzerland

²Private Practice, Nyon, Switzerland

³Faculty of Medicine, Institute of Social and Preventive Medicine, University of Geneva, Geneva, Switzerland

⁴Faculty of Medicine, University of Geneva, Geneva, Switzerland

⁵Department of Public Instruction, Geneva School Health Service, Geneva, Switzerland

AIM:

To assess immunization status and analyze potential variations according to sociodemographic variables in a youth clinic in Geneva

BACKGROUND:

Worldwide, adolescents are under-vaccinated and have limited access to preventive health care. In Europe, vaccination of adolescents is brought to focus because of ongoing measles epidemics, increasing cases of whooping cough, Hepatitis B and Human papillomavirus (HPV) vaccination campaigns. Still, data about adolescent vaccination in Europe are scarce.

METHOD:

Immunization status was assessed retrospectively with Tetanus and measles as indicators of childhood immunization as well as Hepatitis B and HPV. Sociodemographic data was collected (age, sex, nationality, duration of stay in Switzerland for foreigners).

RESULTS:

All new patients (N=390) of Geneva University Hospital 's Youth clinic were included between January 2010 and June 2011. Vaccine coverage was low for all vaccines regardless of sex or country of origin. 89% of young people tested (mostly recent immigrants with no available immunization data) had tetanus antibodies indicating adequate childhood immunization. Hepatitis B and HPV coverage was low especially in recent immigrants.

CONCLUSION:

This is one of the few studies showing data on Tetanus antibodies in a clinical sample of adolescents and young adults. Systematic assessment of immunization status and individually adapted catch-up plan allows better adolescent vaccine coverage and improves safety by avoiding unnecessary dosis. It also allows addressing barriers to vaccination and individual counselling of various health and preventive issues with the adolescent.

Non-alcoholic fatty liver disease, an actual problem!

Susana Grilo Lourenço¹, David Rodrigues¹, Marta Lopes¹, Nídia Nunes¹, Teresa Pereira Leite²

¹USF Planície, ARS Alentejo, Évora, Portugal

²USF Alcoides, ARS Alentejo, Montemor-O-Novo, Portugal

Non-alcoholic fatty liver disease is the accumulation of fat in the liver of people who drink little or no alcohol. Is more common than alcoholic liver disease owing to the rapid rise in the prevalence of obesity and it usually causes no signs, no symptoms and no complications. In some people can progress to liver failure. Biographical research of clinical guidelines, systematic reviews, and meta-analysis in English and Portuguese, published in the last 5 years, in Medline database employing the MeSH terms: "non-alcoholic fatty liver disease". Non-alcoholic fatty liver disease is now the commonest cause of abnormal liver function tests. The exact prevalence is not known, but affect up to a third of the population in many developed countries and up to 70% in patients with type 2 diabetes mellitus. Between 10% and 30% of patients can progress to cirrhosis. It usually causes no signs and symptoms. Many patients remain undiagnosed, and recognizing those at risk is the first step. Liver biopsy is the gold standard method for diagnosis and staging, but the majority of patients can be effectively diagnosed non-invasively with tests that are routinely available in the clinic nowadays. No standard treatment exists. Lifestyle interventions aimed at weight loss and increased activity are essential for all patients in its treatment. For patients who fail lifestyle intervention, liver-directed pharmacotherapy with pioglitazone or vitamin E can be considered. Features of the metabolic syndrome and cardiovascular risk factors are very common, so all patients should be screened for these and have they managed aggressively. For patients who develop advanced disease, they require surveillance for and management of the complications of cirrhosis. Non-alcoholic fatty liver disease affected approximately 30% of the population and can cause significant liver disease. Accurate diagnosis and staging are important in determining the appropriate long-term management for patients.

Keywords: NON-ALCOHOLIC FATTY LIVER DISEASE, LIVER DISEASE

Sattar Naveed et al: "Non-alcoholic fatty liver disease". BMJ. July 2014.

Dyson JK et al: "Non-alcoholic fatty liver disease: a practical approach to diagnosis and staging". Frontline Gastroenterology 2014.

Dyson JK et al: "Non-alcoholic fatty liver disease: a practical approach to treatment". Frontline Gastroenterology 2014.

Non-alcoholic fatty liver disease is now the commonest cause of abnormal liver function tests. The exact prevalence is not known, but affects up to a third of the population in many developed countries and up to 70% in patients with type 2 diabetes mellitus. Between 10% and 30% of patients can progress to cirrhosis.

Non-alcoholic fatty liver disease usually causes no signs and symptoms. When it does, they may include fatigue, pain in the upper right abdomen and weight loss.

Many patients remain undiagnosed, and recognizing those at risk is the first step. Liver biopsy is the gold standard method for diagnosis and staging, but the majority of patients can be effectively diagnosed non-invasively with tests that are routinely available in the clinic nowadays.

No standard treatment exists. Lifestyle interventions aimed at weight loss and increased activity are essential for all patients and if sustained are effective in its treatment. For patients who fail lifestyle intervention, liver-directed pharmacotherapy with pioglitazone or vitamin E can be considered.

Features of the metabolic syndrome and cardiovascular risk factors are very common, so all patients should be screened for these and have them managed aggressively. For patients who develop advanced disease, they require surveillance for and management of the complications of cirrhosis (hepatocellular carcinoma, varices, and osteoporosis).

Is obesity more than just excess of fat? An analysis using impedanceometry on overweight patients and type I obesity (OI)

Clara Casas, Inmaculada Gil, Yuri Ochiai, Isabel Boba, Mariam De La Poza, Guadalupe Fernandez, Roxana Zevallos
Dr Carles Ribas Health Center. Barcelona city. Institut Català de la Salut.

Obesity is a major health issue worldwide, both for its economic impact as well as the various pathologies it implies. In our facilities we are using basic weight and height scales to calculate the body mass index (BMI) to classify overweight patients. The aim of this study is to test the use of impedanceometry in primary care to add further valuable information on the patient's body composition in order to better adjust its treatment.

Goals:

1. Assess the proportion of visceral fat (VF) in patients with OW and OI.
2. Describe the presence of decreased levels of lean mass (LM) in these patients, which might condition the appearance of sarcopenia.

METHOD: Descriptive observational study. Sample: Randomly selected the first 100 OW or OI patients who attended the primary care consults during two weeks time.

Variables: BMI, % fat mass (FM), % fat-free mass (LM) and VF measured with OMRON BF 511.

Analysis executed with SPSS 20 statistic, chi-square test.

RESULTS:

Sample description:

56% women, average age 63 years (25-89). OW: 49%; OI 51%

54% hipertension, 22% diabetes mellitus, 42,4% dislipaemia.

Global impedanceometry:

Low Normal High Very high

FM 0 4% 17% 79%

VF 0 20% 45% 35%

LM 77 22 1 0

LM and VF analyzed by sex:

Low Normal High

LM men 90,9% 9,1% 0%

LM women 66,1% 32,1% 1,8%

P<0,03

Normal High Very high

VF men 6,8 29,5 63,6

VF women 30,4 57,1 12,1

P <0,000

CONCLUSIONS:

1. We observed a high prevalence of high or very high visceral fat in overweight and type I obesity patients, more predominantly in men.
2. In these patients, a low percentage of lean mass is noted.
3. When prescribing a diet, to assess its progress we should be able to monitor the loss of visceral fat, aiming to lower the risk of cardiovascular events.
4. It is crucial to prescribe physical activity along with diet in these patients, to improve lean mass and thus lower the effects sarcopenia might have on their global health.

Evidence of prostate cancer in general practitioner clinic – evaluation of screening

Jana Luptakova¹, Lucia Kukuckova²

¹General practitioner clinic, Lucenec, Slovakia

²General Practitioner clinic, Dunajska Streda, Slovakia

Background & AIM: Prostate cancer is the most common cancer of the urogenital system. The incidence of prostate cancer is continuously increasing in Slovakia as well as worldwide.

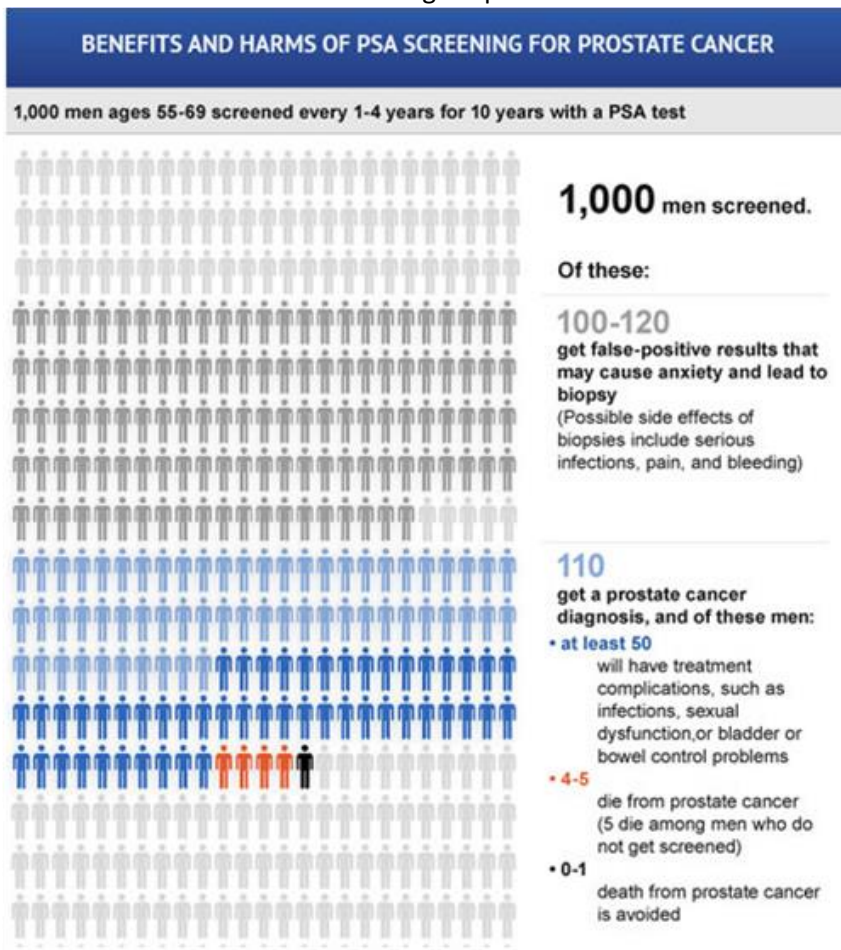

METHOD: The screening of male over the age of 50 years contributes to increasing incidence of prostate cancer. This article analyses the outcomes of preventive examinations of males over the age of 50 years over the period of 3 years in our general practitioner clinics.

RESULTS: Prostate cancer is the third most common malignant tumor in males, following lung cancer and colorectal carcinoma, as it was seen in our results too.

CONCLUSIONS: Our conclusion was to emphasise the importance of periodic preventive examination at general practitioners with recommendation of necessity of preventive urological screening over the age of 50 years, and in the case of positive family case history of prostate cancer over the age of 40 years.

Consultation in Family Medicine – the importance of systematization

Sara Martins, Catarina Fernandes, Helena Beça
Espinho Family Health Unit, Espinho, Portugal

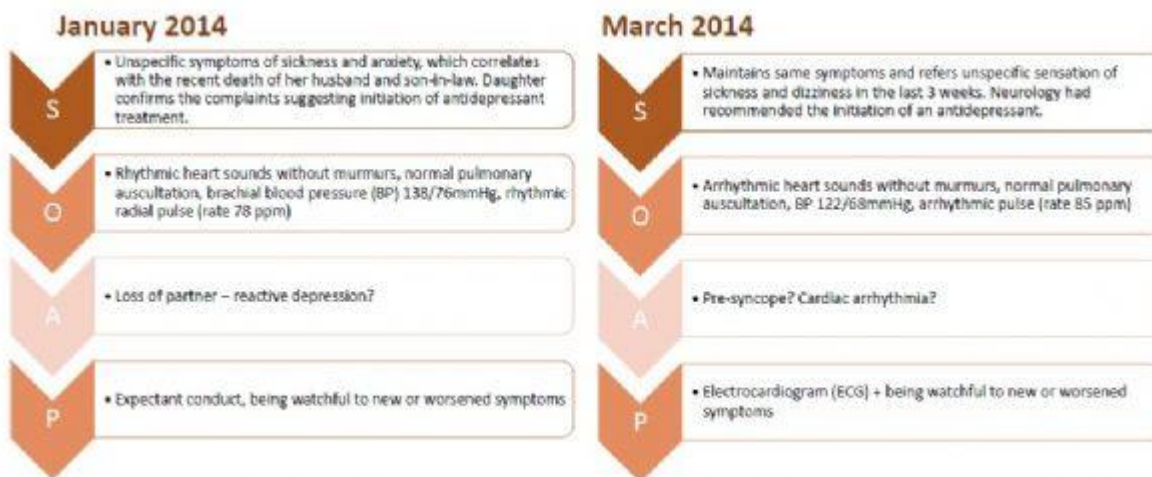

Context: For Family Medicine (FM) it is well recognized the importance of a person-centered care, where problems are approached in a holistic model, which makes FM unique. This discipline enhances a singular consultation process that improves the patient-doctor relationship, which will keep evolving. Compared to secondary care the decision process differs, since a reasoning based on probabilities is necessary. In spite of the well-known advantages, there is a possibility that they can lead to a predisposition of medical errors if pre-defined and systematized strategies are omitted from the clinical practice.

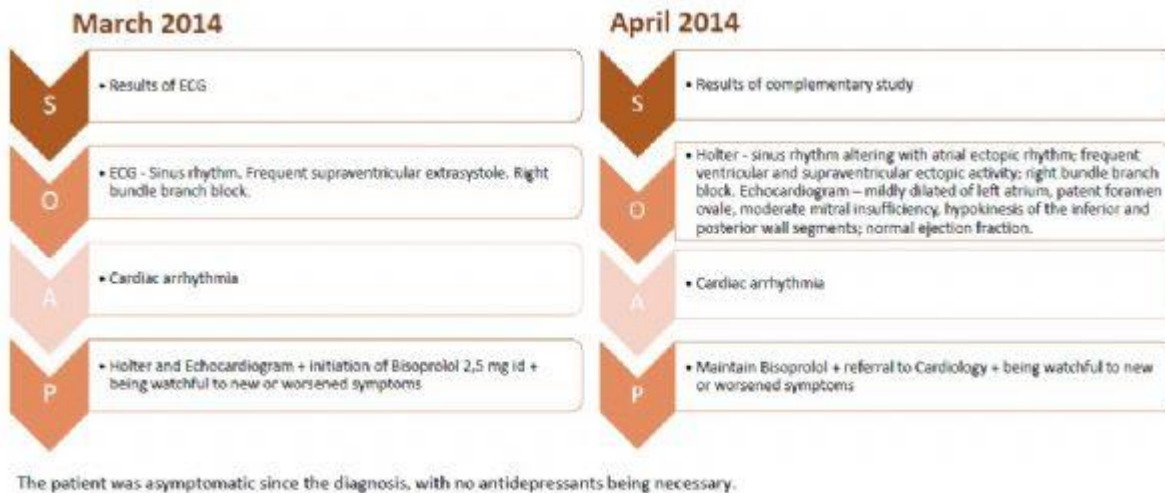

Case description: CF, 83 years, female, widowed, retired, with a personal history of ischemic stroke in 2011 (without sequelae). In January 2014 she visits her family physician (FP) expressing unspecific symptoms of sickness and anxiety, which correlates with the recent death of her husband and son-in-law. Her daughter confirmed the complaints suggesting initiation of antidepressant treatment. After complete physical examination, with no significant alterations, it is negotiated with the patient to maintain an expectant conduct, being watchful to new or worsened symptoms. In March 2014, the patient returns describing signs compatible with a pre-syncope. Meanwhile, during an appointment with her neurologist, an antidepressant is suggested. The patient decided to wait for her FP’s opinion who, at newer complete examination, detected an arrhythmic pulse and heart sounds. The complementary study revealed a cardiac arrhythmia. Clinical improvement was verified with no antidepressants being necessary.

DISCUSSION: The profound knowledge of the bio-psycho-social patient context is one of the most fundamental tools for decision making in primary health care. Paradoxically, it can also confuse it, in the absence of a solid systematized model for anamnesis and objective examination, applied to all consultation with no exceptions. But is this systematization need sustainable? What strategies should be adopted to avoid missing the fundamental steps?

Keywords: systematization; consultation; decision making; holistic model

Dealing with uncertainty in Family Medicine – Medically Unexplained Symptoms

Joana Pinto Carneiro¹, Sofia Correia Pinto², Inês Bento¹, Albina Oliveira³, João Julio Cerqueira⁴

¹usf garcia de Orta, porto, portugal

²usf s.João do Porto, porto, portugal

³usf oceanos, matosinhos, portugal

⁴usf horizonte, matosinhos, portugal

Background and AIM: In Primary Health Care, 15 to 50% of the symptoms are not explained by a specific underlying known condition. Recent studies admit the existence of a distinct health issue – Medically Unexplained Symptoms (MUS). MUS has earned increasing interest due to the significant morbidity, frequent absenteeism from work and economic burden associated to it. It is also associated to higher risk of iatrogenesis due to increased “doctor shopping”, investigation and hospitalization. Doctors and patients often experience frustration and helplessness in consultations around MUS.

We intend to raise awareness regarding this entity, it’s epidemiology, characteristics and adequate management to ultimately improve health outcomes.

METHOD: Bibliographic research using the MeSH terms “medically unexplained symptoms”, “management” and “primary health care”, including articles in english and portuguese.

RESULTS: The management of patients with MUS can be divided into 5 steps – prevention and self-management, identification of MUS, physical and psychological assessment, intervention (according to MUS intensity - low, moderate or high) and reassessment.

CONCLUSION: When managing MUS it is essential to assess the patient in a holistic manner approaching both physical and psychological needs whilst motivating the patient in taking part of the decisions. Family doctors have an important role in optimizing the management of MUS, improving patient-doctor relationship, improving life quality and consequently diminishing health costs.

Keywords: medically unexplained symptoms, primary health care, management.

Obesity and overweight - primary care intervention

Inês Espiga Macedo¹, André Lourenço¹, Ana Rocha¹, Pedro Castro¹, Sofia Baptista²

¹USF Modivas, ACeS Póvoa Varzim/Vila do Conde, Vila do Conde Portugal

²USF Serpa Pinto, ACeS Porto Ocidental, Porto, Portugal

INTRODUCTION: Obesity and overweight are nowadays considered an epidemic and a public health problem. Unhealthy diet and physical inactivity are amongst the major risk factors for these health problems. Primary care physicians have a privileged place for intervening in this problem.

PURPOSE: The purpose of this study was to evaluate the results of an intervention in overweight and obesity in a primary care consultation.

METHODS: Retrospective analytical study based on data from the electronic file of patients with codification of obesity and overweight in the years of 2013 and 2014. The exclusion criteria were patients with less than 2 consultations from the date of the initial intervention (diet and physical activity recommendations and motivational interview).

RESULTS: A total 43 patients were analyzed, with a mean age of 54 years (min: 26; max:80), 67% were women. BMI at the last evaluation had a mean value of 34,5. From the total, 53% achieved a mean loss weight of 3.3kgs.

DISCUSSION: Obesity has major social and psychological consequences therefore primary care health services can and need to have a concerted sustained multidisciplinary sustained action towards the main purpose of the global strategy of WHO. The results demonstrate the importance of a brief but sustained intervention based on simple strategies of motivation for a healthier lifestyle.

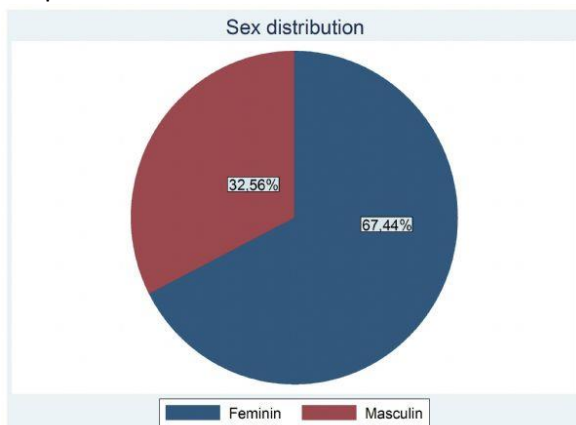

Note: These are still the preliminary results of the study that will attend to consultations made until June 2015.

Keywords: obesity, overweight, primary care, intervention.

Vitamin D supplementation: actual evidence recommendations

Silvia Martins¹, Pedro Cardoso Ferreira²

¹Unidade de Saúde Familiar Lagoa, Unidade Local de Saúde de Matosinhos

²Unidade de Saúde Familiar Dunas, Unidade Local de Saúde de Matosinhos

Background & Aim

Vitamin D (VitD) deficiency is a highly prevalent condition and is a worldwide public health problem, affecting all age groups. Some studies have shown an association with increased fracture risk, functional limitations, cancer, hypertension, diabetes, cardiovascular disease, dementia, depression and death. There is evidence that timely diagnosis allows early therapy in risk groups.

The aim of this review is to summarize the most common indications of VitD supplementation based on actual evidence.

Methods

PubMed based review was made of English and Portuguese publications: reviews, guidelines and clinical orientation norms between 2005 and 2015 were included.

MeSH terms: vitamin D deficiency; treatment;

Results

Endocrine society recommends measuring serum VitD levels as also its supplementation only in risk patients: malabsorption syndromes; reduced VitD intake; medication that interferes with VitD metabolism; darker skin pigmentation; low exposure or contraindication to sunlight radiation; laid up or nursing homes patients; obese; patients with personal history of falls or fractures; pregnant; infants; postmenopausal women; rickets; osteomalacia; osteoporosis; chronic kidney disease; hyperparathyroidism; granulomatous diseases and lymphomas.

Actually, there is no consensus about VitD serum levels to diagnosis of VitD deficiency.

Supplementation is recommended with D2 or D3 vitamin. A loading dose is recommended followed by a maintaining dose and which depend on severity of VitD deficiency and complications prevention.

Discussion

Actual evidence is not consensual respect either risks or benefits of VitD levels screening and VitD supplementation to prevent VitD deficiency in general population.

Its cost-effectiveness is demonstrated only in risk groups.

Having a patient-centered care, it is important to family physician to be warned to risk patients and initiate proper investigation before beginning VitD supplementation. It should be aware about referrals to secondary care of chronic disease patients with difficult management.

Keywords: MeSH terms: vitamin D deficiency; treatment;

Suicide Prevention: The Role of Primary Health Care Services

Monica Mota¹, Sara Vieira¹, Joana Silva², Rui Correia¹, Ricardo Santos¹, Inês Melo Sousa¹, José Carvalho¹, António Filipe¹

¹Family Health Unit Alpendorada, Agrupamento de Centros de Saúde Tâmega I, Marco de Canaveses, Portugal

²Department of Psychiatry and Mental Health, Centro Hospitalar Tondela Viseu, Viseu, Portugal

Background & AIM: Suicide is the tenth leading cause of death worldwide and a complex and important public health issue. In Portugal, suicide rate is higher than the average European rate. About 80% of patients who commit suicide have resorted to primary health care service (PHCS) in the year preceding it, and half did so in the month of their death, which are numbers above those recorded for mental health services (MHS). PHCS providers often have the opportunity to intervene in suicide prevention. This work intends to make a review of the existing literature on suicide prevention within the PHCS.

METHOD: A review of the literature was performed by the terms "suicide", "prevention" and "primary health care", using online databases, textbooks and scientific journals.

RESULTS: Literature shows that suicide risk can be minimized by detection of individuals at higher risk and by starting appropriate treatment. For the assessment it must be considered the age, sex, race, marital status, religious involvement, presence of mental illness, social support, domestic violence, certain medical conditions, access to lethal methods, existence of previous attempts and analysis of verbal and non-verbal language. It is essential to inquire the patient about the existence of suicidal ideation or plans. The identification of individuals at high/imminent risk and the existence of family and social support networks are essential to decide for an outpatient based treatment or referral for evaluation in MHS.

CONCLUSIONS: A visit with to the primary care provider may be the only chance for the suicidal patient to engage with the health care system and access treatment. The particularities of the PHCS and the fact that its professionals monitor patients not followed in MHS, give them an important role in the identification and orientation of individuals at risk for suicide, and thus to act on its prevention.

Warning Signs... Which Patients Should be Evaluated for Suicide Risk? Factors to Consider in Suicide Risk Assessment

Warning signs... Which Patients Should be Evaluated for Suicide Risk?	
"IS PATH WARM?" Ideation; Substance abuse; Purposelessness; Anxiety; Trapped; Hopelessness; Withdrawal; Anger; Recklessness; Mood change	
Factors to Consider in Suicide Risk Assessment	
Risk factors	<ul style="list-style-type: none">- Previous suicide attempt, family history of suicide- Mental disorders (depression, schizophrenia, anxiety and personality disorders, alcohol and other substance abuse)- Impulsive and/or aggressive tendencies- Anhedonia, severe anxiety/panic, insomnia, command hallucinations, intoxication, self-hate- Major physical illnesses (especially chronic conditions like chronic pain)- History of trauma or abuse- Lack of social support and increasing isolation- Easy access to lethal means- Barriers to accessing health care
Precipitants or triggering events	<ul style="list-style-type: none">- Important loss (of a relative/ friend/ relationship/ health or financial status)- Family conflict- Life events leading to humiliation or shame- Exposure to suicide of other people from the same community or famous people
Protective factors	<ul style="list-style-type: none">- Life satisfaction- Easy access to health care and development of strong therapeutic relationships- Social and family support; belongingness; sense of responsibility to others- Coping and problem-solving skills- Religious faith

Mnemonic IS PATH WARM? based on the recommendations of the American Association of Suicidology and the

American Psychiatric Association.

Modified SAD PERSONS Scale

Modified SAD PERSONS Scale		
S	Male Sex	1
A	Age < 19 or > 45 years	1
D	Depression/ hopelessness	2
P	Previous attempts/psychiatric monitoring	2
E	Ethanol or other substance abuse	1
R	Rational thinking loss	2
S	No Spouse (if divorced, widowed, separated, or single)	1
O	Organized plan	2
N	No social support	1
S	Stated future intent	1

Modified SAD PERSONS Scale, according to Oxford Handbook of Emergency Medicine (2006). The score is calculated from ten yes/no questions, with points given for each affirmative answer as shown in the figure. If the patient scores 0-5 points it may be safe to discharge (depending upon circumstances); if scores 6-8 points probably the patient requires psychiatric evaluation; if scores >8 probably the patient requires immediate Hospital admission.

Orientation of the Patient with Suspected Suicide Risk in Primary Health Care Services

Orientation of the Patient with Suspected Suicide Risk in Primary Health Care Services		
Suicide Risk	Risk Factors, Warning Signs and Protective Factors	Action Based on Level of Risk
High acute risk	<ul style="list-style-type: none"> - Persistent ideation - Strong intention to act/existence of plan - Not able to control impulse - Recent suicide attempt/ preparatory behavior - Acute state of mental disorder - Precipitating events - Inadequate protective factors 	<ul style="list-style-type: none"> - Maintain direct observational control of the patient - Limit access to lethal means - Immediate transfer with escort to Emergency Care Setting for Mental Health Service (MHS) support
Intermediate acute risk	<ul style="list-style-type: none"> - Current suicidal ideation - No intention to act - Able to control the impulse - Without recent attempt/ preparatory behavior - Presence of risk factors or warning signs in a patient with limited protective factors 	<ul style="list-style-type: none"> - Refer to MHS for evaluation (contact the MHS provider to determine the acuity of referral) - Limit the access to lethal means
Low acute risk	<ul style="list-style-type: none"> - Recent suicidal ideation or thoughts - No intention to act/no plan - Able to control the impulse - Without previous attempts - Existence of protective factors - Limited risk factors 	<ul style="list-style-type: none"> - Treat presenting problems (depression, anxiety, ...) - Address safety issues - Promote strengthen of social and family support networks - Document the therapeutic strategy - Consider consultation with MHS provider if the patient has an unsatisfactory response to treatment
<p>If no increased acute risk, continue routine care/ treatment of the underlying condition and periodically reassess the risk.</p>		

Orientation of the Patient With Suspected Suicide Risk in Primary Health Care Services. According to the recommendations of VA/DoD Clinical Practice Guideline for Assessment and Management of Patients at Risk for Suicide (2013), Evaluation and Treatment of Patients with Suicidal Ideation (published in American Family Physician, 1999) and Suicide Prevention Toolkit for Rural Primary Care (Suicide Prevention Resource Center, 2013). MHS - Mental Health Services.

Overweight asymptomatic patients in GP practice-biochemical approach to understand illness

Ilze Skuja¹, Gita Krievina¹, Inga Stukena², Aivars Lejnicks²

¹Riga Stradins University

²Riga Eastern Clinical University Hospital

Background and Aim. Adiposity is a world-wide problem which leads to Diabetes Melitus Type2 (DM), nonalcoholic fatty liver disease (NAFLD) and coronal heart disease (CHD). Unfortunately patients with enhanced BMI think that they are healthy. They often do not have any symptoms or limitations of life quality and don't notice how illness is approaching stealthily. The aim of this work is to find patients with DM, NAFLD, CHD in early asymptomatic stages.

Methods. In 159 patients (30-45 years, asymptomatic) glucose (Glu), HOMA-IR, Total cholesterol (TC), HDLC, non-HDLC, LDLC, triglycerides (TG), GGT, AST and ALT were estimated. VCAM, tPAI-1, chemerin and E-selectin levels were measured by Luminex xMAP technology. Patients were divided into three groups according to BMI- normal weight, overweight and obese. All biochemical parameters and cytokines were compared between groups.

Results. Significant ($p < 0.05$) positive correlations between BMI and ALT ($r = 0.28$), AST ($r = 0.42$), GGT ($r = 0.43$), TG ($r = 0.49$), Glu ($r = 0.36$), HOMA-IR ($r = 0.67$), tPAI-1 ($r = 0.33$), VCAM ($r = 0.54$) and negative correlation between HDLC ($r = -0.36$) and chemerin ($r = -0.33$) were found in the whole group. There were significant ($p < 0.05$) differences in levels of glucose (Glu), HOMA-IR, HDLC, non-HDLC, TG, GGT, AST, ALT, VCAM, tPAI-1, chemerin and E-selectin between normal weight, overweight and obese patient groups.

Conclusions. Differences in cytokine levels between groups showed the inflammation process and higher risk of CHD, NAFLD and DM of overweight and obese persons. It is too expensive to make such cytokine analyses in GP practice, but even every day used biochemical analyse such as HDLC, Glu, HOMA-IR, TG, ALT, AST and GGT had statistically significant differences. It is wise to measure level of Glu, ALT, AST, GGT, HDLC and TG in overweight and obese patients in GP practice to diagnose illnesses in earlier stages and to start quicker treatment and prophylaxis.

Iron deficiency anemia in young adult man after wet-cupping therapy (Al-hijamah)

Didem Sunay, Nevgül Demir, Feyza Yücel, Rukiyye Türker

Department of Family Medicine, Keçiören Training and Research Hospital, Ankara, Turkey

Background and AIM: Wet cupping therapy (WCT) that was used in Europe at middle ages, at the present time has been used as an alternative treatment method throughout the world. In Asia, Muslim people, because of religious beliefs, are very interested in Al-hijamah, which is one of the WCT methods used in prophetic medicine and is recommended by prophet Muhammad. Al-hijamah was reported to decrease serum ferritin in healthy subjects. In this case report we submitted a young adult man with iron deficiency anemia which was developed probably after Al-hijamah.

METHODS: A 40-year old man attended to the out-patient clinic of family medicine department with dizziness and weakness. No pathological finding was determined in his physical examination. Laboratory findings were; hemoglobin 11.1g/dl, hematocrit 36.3%, MCV 69.7f L, RDW %30.5, iron 25ug/dl, ferritine 6.3 ng/ml.

RESULTS: The patient was diagnosed with iron deficiency anemia. Research for gastrointestinal bleeding was planned, but he refused advanced research and noted that he occasionally gave blood for polycythemia by himself, that once he had told to have this disease. Although he has not give blood for several years, last year he received Al-hijamah for hot flushes and heat intolerance, and lost 500 ml blood in this intervention. This blood lost was thought to be the reason of his anemia but fecal occult blood assessment was done. 100 mg per day iron supplementation was started to the patient after the negative results of 3 times repeated fecal occult blood assessment. One month later his laboratory results were; hemoglobin 12.5g/dl, hematocrit 39.7%, MCV 74.2f L, RDW %21.7, iron 45ug/dl, ferritine 14.3ng/ml.

CONCLUSION: It can be said that our patient had had anemia before procedure that became deeper after it. As primary care physicians we should question our patients with anemia for such procedures.

Organisation of Turkish Speaking Healthcare Professionals Associations Around Europe

Cemal Kavasogullari¹, Cemal Sakalli¹, Cankut Yuksel², Serdar Dalkilic², Kandemir Berova²

¹Turkish Cypriot Healthcare Professionals Association

²European Federation of Turkish Healthcare Professionals

Background and Aim

Literature shows patients who belong to minority groups are more likely to consult healthcare professionals of the same race or ethnic group. It is also well documented that minorities or ethnic communities are less likely to have access to healthcare services or are worse at utilizing available healthcare resources compared to the native population. Research from Germany, UK and various other European countries show that Turkish Speaking Population living in European countries do belong to this under-served population with particular problems in accessing healthcare. We hereby present European Federation of Turkish Healthcare Professionals (EFTHP), an umbrella organisation established around Europe. EFTHP and member organizations aim to provide Turkish speaking community in their respective countries with educational and informative activities locally in order to improve their health, well-being and access to healthcare.

Method

Number of Turkish speaking population in each country have been obtained from embassy and consulate resources where available. Member sizes of each organisation has been obtained from EFTHP archives and graphed according to population served. Countries and locations of each organisation has been shown on a map and contact details have been provided.

Results and CONCLUSIONS:

Turkish speaking communities in Europe has significantly worse access to healthcare resources. Number of Turkish speaking healthcare professionals across the European continent has constantly increased over the last 10 years but this raise is not proportional to the increase in Turkish speaking migrant population. Activities of member organisations have been well perceived by the communities but there is significant gap between demand and supply. There currently are 11 member organisations from 5 EU countries -Germany, France, Austria, United Kingdom, Switzerland- and 2 Non-EU countries -Turkish Republic of Northern Cyprus, Turkey-. There are 2004 registered members in total as of May 2015.

Patient-Centered Medical Home Curricular Development Utilizing Weight Management Group Visits to Teach Group Facilitation and Leadership Skills

Susan Saffel Shrier, Katherine Fortenberry, Rebecca Cannon, Sydney Abbott

Department of Family and Preventive Medicine, University of Utah School of Medicine, Salt Lake City, Utah, USA

BACKGROUND & AIMS:

Group visits are an ideal venue for teaching Patient-Centered Medical Home concepts and meeting ACGME Milestones competency requirements. The primary goal of this project was to develop a program to teach resident group facilitation and leadership skills, while improving patient access and team-based delivery. Secondary goals include enhancing residents skills in nutrition knowledge, weight management, and motivational interviewing.

METHODS:

Group Visits

Family medicine resident participates in three consecutive group sessions, along with either a faculty clinical psychologist or registered dietitian nutritionist. Residents first review online group facilitation and leadership material, and complete pre/post nutrition/obesity knowledge and obesity attitudes surveys. Each resident observes and participates in the first two sessions, and leads the third session. The faculty member provides debriefing and feedback using the group facilitation competency evaluation.

Material Development

Evidence based program topics were selected based upon an exhaustive literature review. Literature review for program development included: international and national obesity guidelines, weight management RCTs (diet, exercise, and behavior), recent systemic review articles. A similar process was conducted in the development of the group facilitation education materials, resident evaluation, and obesity attitude surveys. Periodic review and revision of materials is ongoing.

RESULTS:

An eight week workbook was created based on the identified evidence based topics, Figure 1. The program involves a holistic approach to weight management to include biological, psychological and social aspects, Figure 2. Each session emphasizes individual goal setting, Figure 3. In addition, a resident Group Facilitation Skills Checklist was developed to evaluate effective teaching, group dynamics, problem solving and motivational interviewing, Figure 4.

CONCLUSION: The Patient-Centered Medical Home concept includes care delivery via group visits. Group visit development and resident facilitation training are enhanced with a weight management and team approach format. The group visit is ideal for addressing the global obesity epidemic.

Oral and Dental Health Conditions of Patients Attending to Ankara University Faculty of Medicine, Family Medicine Polyclinics with Family Medicine Perspective

Zeynep Bayraktutar Daldal¹, Zehra Dağlı², Mehmet Urgan²

¹mamak onur uğurlu family helath center, ankara, turkey

²department of family medicine, ankara üniversity,ankara,Turkey

Children or adults do not visit a dentist regularly, but do consult only when they have symptoms. Through primary care preventive medicine practices, disorders that could affect general health can be prevented by early detection and early intervention as a result of periodic health examinations. Thinking each family physician consultation as an opportunity for oral and dental health, we aimed to identify our patients' oral and dental health status during physical examination due to other reasons for encounter. Between April 1, 2014 – June 31, 2014 three hundred twenty-eight people were interviewed face to face. Oral and dental examinations were performed by the same family physician in family medicine clinical setting..While 53.7% of the respondents had at least one decayed tooth, 64% had at least one missing and 87.5% had at least one filled tooth, and 65.2% of the respondents had tartar. In the presence of cardiovascular and respiratory diseases, diabetes mellitus and rheumatic diseases, DMFT index was significantly higher. In comparison of DMFT index with medical treatment, usage of antihypertensive, antidiabetic, antihyperlipidemic and anticoagulant drugs increased the DMFT index, that increase was statistically significant. While first dental examination gets older, DMFT index also increased. Increased frequency of tooth brushing gradually decreased DMFT index. The ratio of daily use of the auxiliary cleaning products was 15.5%. In conclusion, individual oral hygiene habits are inadequate. Patients do not share their problems on oral health status, unless they are especially questioned. Family physicians have an important role in ensuring periodical health control habits, provision of oral hygiene and proper nutrition education, and informing individuals especially since early childhood. it may turn the attendances of the patients to primary care into an opportunity to protect oral and dental health of the patients who do not receive regular dental care.

Vaccination Rates of The Students Studying in Primary and Secondary Schools in Yenişehir, Diyarbakir

Funda Gökğöz Durmaz¹, Fatma Gökşin Cihan², Ahmet Yılmaz³, Hamza Aslanhan³, Halil Yendim¹

¹Diyarbakır Yenişehir Toplum Sağlığı Merkezi

²Necmettin Erbakan Üniversitesi Meram Tıp Fakültesi Aile Hekimliği Ana Bilim Dalı

³Dicle Üniversitesi Tıp Fakültesi Aile Hekimliği Ana Bilim Dalı

AIM: In this study, we aimed to determine the immunization rates of the students studying in primary and secondary schools, in a vaccination operation conducted by Yenişehir Community Health Center and to reveal the difficulties encountered.

METHOD: This study was a cross-sectional descriptive study. Previously, a written consent form was sent to the school administrators and parents. Doctors and nurses went to schools in Yenişehir district between 27.11.2014-29.12.2015. Vaccines, procured by Diyarbakır Public Health Directorate, were implemented to kindergarten, first class and eighth class students. The number of applied vaccinations were recorded to the ministry information systems.

RESULTS: During the vaccination operation, 47 central and 20 rural schools, a total of 67 schools, were visited. According to the national vaccination schedule, Measles, Mumps and Rubella (MMR) vaccine were administered to kindergarten students. Diphtheria, tetanus, acellular pertussis, inactivated polio vaccine (quad combination vaccine) and MMR were administered to first class students; tetanus adultive diphtheria (Td) were administered to eighth class students. 1295/2609 (49.63%) of kindergarten students were vaccinated. 4042/5477 (73.79%) of first class students were vaccinated with MMR and 75.36% (n: 4128) were vaccinated with quad combination vaccine. 2930/5086 (57.60%) of eighth year students were vaccinated with Td.

CONCLUSIONS: The vaccination schedule differs by socio-economic conditions, migrations and the geographic location associated with epidemics of infectious diseases for every nation. To implement the booster doses in vaccination schedule without any missing is very important in terms of ensuring full immunity and disease eradication. In our study, vaccination rates in the district of Yenisehir was found well below the expected level. The preconception "MMR vaccine constitutes SSPE" in parents of kindergarten and first grade students, reduced vaccination rates. Training seminars should be organized to increase public awareness and to correct misinformations.

The Relation of Asthma and Allergic Diseases Diagnosed by Doctor with Fast Foods in Schoolchildren

Betül Battaloğlu Inanç

Muğla Sıtkı Koçman University, Faculty of Medicine, Family Medicine Department

OBJECTIVE: It would not be right to link the reasons for the worldwide increase in incidents of childhood obesity and those of allergic diseases only to genetics. Obesity, asthma and allergic diseases can be prevented through the consumption of healthy food. In this study, children's eating habits, obesity, asthma and other allergic diseases were intended to determine their relationship with each other.

METHODS: In a high socioeconomic level school in Mardin, asthma and allergic diseases of children aged between 7-15 were diagnosed by a doctor, and their eating habits between meals, food types they buy from the school canteen and their family data were determined by survey.

RESULTS: Obesity and overweight was higher with the boys than the girls. 21.7% of the girls, 13.4% of the boys had allergic diseases. Allergic diseases were remarkably frequent with girls ($p<0.0001$). 1.6% of the girls and 2.3% of the boys had asthma. Allergic diseases was higher with the overweight and obese groups. Children who had breakfast regularly had significantly less tendency to be overweight or obese ($p<0.00001$).

CONCLUSION: Genetic predisposition is the most important factor in emerging obesity and allergic diseases. However, it is not possible to explain the worldwide increase of obesity, allergic diseases and asthma only by genetics. The part played by complex dietary factors should be explained for obesity, asthma and other allergic diseases and understood through a multidisciplinary approach.

Short stature and low weight in schoolchildren

Betül Battaloğlu Inanç

Muğla Sıtkı Koçman University, Faculty of Medicine, Family Medicine Department,

AIM: Evaluated the frequency of short stature and low weight between two primary school children aged 6-16 years of children in Mardin province in 2010 and 2011. **MATERIAL-METHOD:** Two elementary school children', heights and body weights were measured. Body mass index (BMI) was calculated with the formula; body weight (kg)/ body height (m²). Short stature and low weight were statistically analyzed. **RESULTS:** There were 834 (51%) boys and 804 (49%) girls. The mean body height, weight, BMI and age was 143.21 ± 13.58 , 38.38 ± 13.06 , 17.86 ± 3.56 and 11.07 ± 2.00 , respectively. Boys mean body height, weight were 142.58 ± 13.92 , 37.87 ± 12.83 , respectively. Girls mean body height, weight were 143.86 ± 13.19 , 38.90 ± 13.29 , respectively. Height and weight difference was so significantly between gender ($p<0.05$), there was no difference between BMI ($p>0.05$). ≥ 85 p. presence of children was statistically significant among the children with short stature ($p<0.00$) There was no one of the children tall in short stature children' ($p<0.00$). There were no difference between growth speed ($p>0.05$). Between schools' in the children BMI ($p<0.00$), height ($p<0.05$) and weight ($p<0.00$) were statistically different

with each other. DISCUSSION: Evaluate of growth and development status for children anthropometry is widely known as a very useful instrument. In school health working children' and family education should be handled together and teachers cooperation should be provide. Growth references lower and upper percentiles. should given to the teachers low or high measurement values should be advise to send the physician control.

Pilot study: dance and anxiety in primary care

Marta Arbolí, Carla Carreras, Jesus Garbayo, Sara Davies, Ana Garcia, Ainhoa Toscano, Joan Campos, Clara Ortí, Maria José Pujol, Maria Dolors Carvallo, Angeles Santos, Pilar Molas
Primary Care Center Chafarinas, Barcelona. Catalan Health Institute. Spain.

BACKGROUND & AIM

The recurring nature and the prevalent condition of the anxiety disorder, specially in women, represents a significant burden to families and society having a high negative impact on the quality of life.

To asses the effect of a dance program in order to reduce the score of anxiety.
Knowing whether there are significant changes in the self perception of health status before and after the intervention.

METHOD

It is a pilot study of a randomised controlled trial (N=30). There are two groups: control and intervention. It has been approved by the Scientific Research Ethics Committee IDIAP Jordi Gol.

The intervention consists in dance sessions, once per week, during 3 months. The purpose is that the patients express themselves with creative movement, not to create a choreography in order to do a performance. The therapist is a young general practitioner with lot of experience in dance and expression.

Inclusion criteria: women from 55 to 65 years old with diagnosis of anxiety disorder, confirmed by a clinical interview and Goldberg's questionnaire.

Both groups were follow up at the beginning of the intervention, at the end of it and three months after it had finished.

Primary outcomes: level anxiety measured through the Goldberg questionnaire.

RESULTS

Including 30 women randomised into two groups initially homogeneous for all variables. Only differences for hypertension ($p=0,025$), dyslipidemia ($p=0,028$) and the intervention group feeling of more walking limitation than the control group ($p=0,032$). The 70% of the participants in the intervention group have done 90% of the sessions. Anxiety score decreases i the intervention group and increases in the control group ($p=0,053$) after the dance therapy intervention. No significant differences in the Euroqol scale.

CONCLUSIONS

Dance therapy could be a useful method to decrease the score of the anxiety disorder measured through Goldberg's questionnaire.

Rational Drug Use Among Nurses Working at University Hospitals

Edibe Pirincci¹, Turgut Bozan²

¹Firat University School of Medicine. Department of Public Health, Elazig

²Training and Research Hospital Diyarbakir

BACKGROUND & AIM: This study aims to examine the attitudes of nurses at university hospitals toward rational drug use and their knowledge about the drugs administered both to themselves and to patients.

METHOD: This is a cross-sectional and descriptive study. The author did a questionnaire form with all the nurses (416 persons) at Elazig Firat University (response rate: 71%). The data collected were entered into the SPSS package program. The confidence interval of the results is 95%, and the threshold for statistical significance is $p < 0.05$.

RESULTS: Of these nurses, 69.2% consult a physician first when they get ill, 96.3% use the drugs prescribed by their doctors, and 76.9% use the drug for the period of time suggested by their doctors. Of them, 87.8% are informed about the effects of the drug they use, 69.2% are informed about the side effects of the drugs they use. The correlation between nurses' checking the expiration date of the drug they use and their age and educational

levels is not statistically significant ($p>0.05$), while their rate of checking this date increases in direct proportion with their length of professional service ($p<0.05$). To the question, "Which drug would you use without consulting a physician when you get ill?" the most frequent response is pain killers, the second is the drugs for colds and the third is antibiotics. The most frequent clinical drug administration error is failing to recollect to administer the drug (40.7%), and the second most frequent error is administering an incorrect dosage of the drug (39%). Of the nurses, 90.2% would like to be trained about rational drug use.

CONCLUSION: The nurses have a lack of knowledge about rational drug use and reported that they do make drug administration errors. These deficiencies should be ameliorated by providing on-the-job training to them.

Keywords: nurse, rational drug use, hospital

Saudi Female School Teachers' Knowledge on and Opinion of Physical Exercise for Children

Ghada A. Al Arfaj, Abdulaziz Al Odhayani

College of Medicine in King Saud University

BACKGROUND:

Studies showed a correlation between physical activities in children and cardiovascular disease risk factors. In Saudi Arabia, there is significant lack in studies evaluating physical activity levels among children.

AIM:

To assess the teachers' level of knowledge regarding the female students physical activity

Methodology

A cross-sectional study.

Place: Al-Abna'a school.

A sample size was 314

Three focus group were conducted to develop and improve the research questionnaire.

Ethical and Legal Considerations were considered.

Results

the research results showed the followings:

- 86.2% of the teachers thought that all female students should have physical activity and physical education classes in school.
- 88% believed that female students are not doing enough physical exercise as they should due to many reasons which include
 - o school-related reasons including availability of fatty and unhealthy food in school (67.3%) and unavailability of PE classes (56.6%);
 - o student-related reasons such as students' preference to do other types of activities (64.8 %) and lack of student motivations (56.1%); and
 - o family-related and other reasons like parental inactivity (61.7%), cost of sport facilities (63%) and cultural disapproval of PE for girls (51%).
- 87.7% represented low levels of knowledge regarding physical exercise recommendation for children.

The CONCLUSION:

The majority believe that physical exercise is important. Teachers' levels of knowledge regarding the recommendation are low. Some barriers were identified such as lack of social and parental support, and lack of suitable facilities.

Falls and Home Accidents at Old Age: A Qualitative Research about the Home Ergonomy and Aging in Place

Suzan Yazici, Serkan Karkuş
Akdeniz University

Background & AIM: Falls are among the main indoor accidents leading to increased morbidity and mortality in old age. It is possible to decrease the rate of accidents and falls at homes. The aim of this study is to evaluate the ergonomy of houses regarding the risk of falls and home accidents, to identify the risky areas at home and to advise recommendations of home adaptation for those areas.

METHOD: Qualitative methodology has been used. 15 interviews have been done at 10 homes in Adiyaman, Gölbaşı district. The Ergonomic Evaluation form has been used to evaluate the ergonomy of the houses. Interviews were audiotaped and pictures were taken. The elderly have been informed about risky areas at their homes and advises were given.

RESULTS: In majority of the houses, the ergonomy was not suitable concerning the physical limitations of the elderly. The stairs have been found as the main place for previous falls. Some participants experienced multiple falls at the same location.

CONCLUSION: Building a safe environment in old age is crucial for the prevention of falls and for an independent life. There is lack of resources available for in-home adaptations which could be beneficial for the elderly living at home.

Acupuncture Treatment for Metabolic Syndrome

Esra Pektaş¹, Sultan Oksuz Zortul¹, Abdussemet Zortul², Özlem Özer¹

¹Department of Family Medicine, Ataturk University, Erzurum, Turkey

²Department of Radiation Oncology, Ataturk University, Erzurum, Turkey

Obesity is the most common public health problem in modern society. It is preventable problem has decreasing rates in developing and developed countries, also in Turkey. Although genetic factors are responsible for %30-70 of obesity, age, gender, consumption diet with high caloric intake, changing conditions of lifestyle and behaviours, decreased physical activity have caused increasing of obesity rate.

Obesity prevalence varies as country and region. Obesity prevalence in adults is %15-60. Obesity may cause both cardiovascular diseases, certain cancers, diabetes, dyslipidemia, digestive, pulmonary, musculoskeletal system diseases and psychologic, psychosocial effects might affect time and quality of life negatively. In addition to diet and exercise programs, affinity of complementary and alternative medical applications have been increased on a large scale to prevent and treat obesity. These treatments are such as phytotherapy, acupuncture and non invasive body shaping. Although some of limitations, effectiveness of these treatments has been seen in scientific literature.

Effectiveness of acupuncture treatment for obesity was exposed in many clinical trials. It can affect appetite, intestinal motility, and metabolism, as well as emotional factors such as stres. Benefits of acupuncture are weight loss, decreased BMI, decreased weight circumference, decreased TG and LDL, decreased fasting blood glucose levels, these are all, components of metabolic syndrome. Metabolic syndrome is related with many kinds of diseases such as, insulin resistance, diabetes mellitus, hypertension, polycystic ovarian syndrome, obstructive sleep apne syndrome. Thus if metabolic syndrome is prevented, other diseases related with it are also prevented. Mechanisms of acupuncture treatment are regulation of neuropeptides, the adipokins, hypotalamus-pituitary-adrenal cortex axis and sympathetic-adrenal cortex axis. Acupuncture treatment is compared with anti-obesity drugs and surgery technics; adverse effects and complications are rare seen and is not invasive and expensive as other methods and it also balances the whole person. It gives them an oppurtunity to experience health.

Evaluation of smoking characteristics and success prevalence of the patients admitted to a smoking cessation clinic in Turkey

Kamile Marakoğlu

Department of Family Medicine, Selcuk University Medical Faculty, Konya, Turkey

Prof. Dr. Kamile MARAKOĞLU1, MD. Nisa Çetin KARGIN1, MD. Rahime Merve UÇAR1, MD. Muhammed KIZMAZ1

1 Department of Family Medicine, Selcuk University Medical Faculty, Konya/TÜRKİYE

OBJECTIVES: In this study, it was aimed to evaluate the prevalence of smoking cessation success in the 1stmonth, 3rdmonth, 6thmonth, 1styear and 2ndyear after smoking cessation in patients who stopped smoking with medical treatment accompanied by behavioral therapy at our smoking cessation clinic.

METHODS: In this cross-sectional and descriptive study, 3322 people who applied to quit smoking were advised one of the most suitable medical treatments accompanied by behavior therapy after their health queries and examinations were made, and Fagerström scores were evaluated. Smoking cessation patients were followed-up clinically and calling after smoking cessation.

RESULTS: The frequency of success in the cases using varenicline in the 1stmonth was 63.5%, in the 3rdmonth 46.8%, in the 6th month 32.1%, 1styear 25.6%, and success rates was 19.9% in the 2ndyear. The success rate in the cases using bupropion in the 1stmonth was 49.9%, in the 3rdmonth 35.6%, in the 6thmonth 26.4%, 1styear 21.9%, and success rates was 16.0% in the 2ndyear respectively. The success rate in the cases using NRT was 53.2%1stmonth, 24.3% in the 3rdmonth, and 27.3% in the 6thmonth, respectively. The frequency of smoking cessation in the cases using varenicline in the 1st,3rd,6th,12thand 24thmonth was significantly higher compared to the cases using bupropion.

CONCLUSIONS: It has been observed in this study that varenicline as a smoking cessation drug is better tolerated than other medications and it seems to be more effective.

Physicians How Much They Know and How Much Aware of the Chronic Hepatitis C: A Study With Questionnaire

Nuket Bayram Kayar¹, Yusuf Kayar², Ahmet Danalioglu², Vusale Gozutok¹

¹Department of Family Medicine, Bagcilar Education and Traditional Hospital, Istanbul, Turkey

²Department of Internal Medicine, Bezmialem Vakif University, Istanbul, Turkey

INTRODUCTION: Hepatitis C virus seroprevalence was reported as an average of 3% across the world and 0.9% in our Country. One of the reasons for the inadequate diagnosis and treatment of hepatitis C is inadequate knowledge and awareness of physicians.

AIM: The aim of this study is to measure the level of knowledge and awareness of physicians about chronic hepatitis C infection.

METHOD: 125 family physicians and 76 internal medicine specialists working in Istanbul were included in the study. The participants were requested to complete questionnaire at the same meeting.

RESULTS: Of the physicians, mean age was 30.9±7.1 years (range 23-45) and 84(42%) male. Four of physicians (2%) had chronic hepatitis C and 12(6%) had never the test. Physician of 17(8.4%) had chronic hepatitis C in relatives.

Answers to questions were as follows: HCV can be transmitted by sexual contact 89%. The maternal transmission is possible 74%. Sharing of shaving materials may cause transmission % 69. In addition, the physicians answered as HCV can transmitted by kissing (17%), by using the same toilet (3%), by working in the same environment (4%). Positive family history of hepatitis C and specialties of physicians were not significant factors to increase the awareness of hepatitis C infection. Physicians between 23-28 age were significantly less aware of hepatitis C.

CONCLUSION: The knowledge and awareness of physicians about hepatitis C infection are not enough to effectively prevent the transmission of infection and to catch the patients who need therapy. So attention should be given to screening programs and the training of physicians in primary care.

The Elli-Khemsin project: Community based participatory research about the loyalty conflict in second generation migrants after 50 years of Moroccan and Turkish immigration

Hulya Tatli¹, Geoffroy Laurent¹, Sabine Wibaut¹, Sergio Costa², Lidwuina Deneys², Lula Baguet², Erol Telyak³, Hamza Assadi³, Meltem Kizil³, Basma Challal³, Yuksel Karaca³, Nassima Bouazziz³

¹ETMS. Private health center Espace Temps, Gilly, Belgium

²AJMO Accompagnement Jeunes en Milieu Ouvert, Charleroi, Belgium

³High school students, Charleroi, Belgium

Introduction

“Would you consider yourself more Turkish or Belgian”? To make a choice between Belgium and Turkey is like making one between my mother and father claims a Belgian-Turkish teenager. That reveals the deep feeling of descendants of Moroccan or Turkish immigration in Belgium we commemorate the 50th anniversary this year. When two objects of desire are in contradiction, that may give rise to loyalty conflict. And that is exactly what we are interested in: the loyalty feeling between parental culture and the one of the native country. This project aims to take interest in the fruits of the immigration and more particularly in the teenagers born of immigrant parents in Belgium by the realization of a video by whom it concerns first, with the help of professionals. How do these teenagers daily manage this far-out situation? The aim of this project is to illustrate these silent questionings. The realized video will be broadcasted in schools to allow other teenagers to identify with the characters and to open up the debate.

Methods

The association ETMS (Private health center Espace Temps) has signed a partnership declaration with the Center of Immigration of Charleroi and the association Accompaniment of Teenagers in Open Custody (AJMO) to elaborate a participatory research in community health. Recruitment of participants, meetings with teenagers, storylines writing, shooting, editing and presentation of the video to an interested audience were the following steps.

Results

A psychologist, a family doctor, a nurse practitioner, a cameraman, social workers, and six teenagers of Turkish, Moroccan or Algerian origin take part to the project that has lasted for one year.

The video will be ready end 2015 and will allow to debate sensitive topics and the creation of a partnership with schools that are interested in using this tool for educational purposes.

The importance of health education in eradicating scabies morbidity: a family case study in Indonesia

Fika Ekayanti

Department of Community Medicine, State Islamic University of Syarif Hidayatullah, Jakarta, Indonesia

Background and Aim

Scabies is a common disease in developing country such as Indonesia. Health education has an important role to prevent the infestation and reinfection of the parasite. The case study aimed to describe the importance of health education for eradicating the morbidity because of scabies.

Case presentation

A male patient showed into clinic on May 2015 with itching. He said the predilection was around hands, inguinal and genital. He said that the symptom occurred first to his son. The nephew who stayed in the boarding school stay for some night and slept in his son's room. They were brought to the clinic around a month ago and have been healed. However, it occurred to him, his wife and his daughter. The morphology of his lesion was unclear. When it was inspected on his wife, it showed clear canalculated lesions. They were medicated with cream permethrin 5% and asked to clean all the household contacts. They were told about the importance of that action to end the transmission of mites.

Discussion

First encounter of the patient's son, the education about importance of prevention for eradicating the mites seemed to be neglected. WHO has recognized scabies as one of community neglected tropical diseases (NTDs). Children who stay in boarding school in Indonesia, which has a tropical climate, is the most vulnerable sector of society. They become the agent for scabies transmission. Education to the patient and family or other related person has an important role to eradicate the manifestation. Commitment of health provider to explain reason for the action, is needed as preventive care.

Conclusion

Scabies as an NTD, has to be prevented by early detection and education to the vulnerable community. Neglecting education would suggest further distribution and recurrence of the disease.

Keywords: scabies, health education, morbidity.

³SUH Hospital de la Ribera

We know from previous studies that smoking is a key factor of production exacerbation and chronic pulmonary disease (EPOC). Given that we see in our consultations a number of high exacerbations because of snuff decided to try to get in EPOC and asthma and even the decline of smoking cessation for control of such patients

Prospective multicenter study of patients with EPOC and asthma intention to leave the snuff and control both exacerbations and subsequent treatment to try to stratify the improvement and the cost of such patients after leaving the snuff

38 patients with COPD / Asthma motivation were selected according to maximum Richmond test (test score October 7 points) and also had a moderate to high dependence (Fragerström test) established and monitored by nurses and doctor to assess progress and adjusting treatment.

the average age of the patients was 50.66 years (55.5 years for men and less for women, 47.9 years). 34.2% of patients were COPD and Asthmatic rest (65.8%)

Three months 70% of patients left the snuff (50% of men but 100% of women) and at 6 months was achieved increase tobacco cessation 80% (rising to 60% men) with a decrease of habit smoking next 90% of patients COPD 40 queries primary care physician were required with a single and 2 emergency hospitalizations and managed to leave the patient at the end of work with 2 drugs bass

Asthma primary care consultations 29 8 fieron necessary and emergency department without specifying income Through this study we show that the involvement of medical and nursing can achieve control of patients with moderate to high motivation to leave the snuff to achieve a clear improvement in the number of exacerbations and complications of chronic respiratory diseases in our consultations

Importance of primary care at fighting against obesity: A case report

Burcu Aykanat, Elif Altunbaş Ateş, Turan Set

Department of Family Medicine, Karadeniz Technical University Medical Faculty, Trabzon, Turkey

BACKGROUND&AIM: Obesity, which is the base to the emergence of many diseases, is a major health problem affecting the survival and quality negatively with increasing incidence. In this study, we aimed to explain the importance of primary care fighting against obesity, by showing a patient who present to primary care, how she lose weight with the implementation of a diet, exercise program and motivational approach.

CASE: A 36-year-old female patient who cannot lose weight for years and who failed in her diet programs before was included in our slimming program by accepting our proposal. When she was attended to our outpatient clinic she was 104.3 kg. She was 1.64 m in height, 118 cm in waist circumference and 133 cm in hip circumference. Her BMI was 38.8 and fat ratio was 44.5%. According to her laboratory findings biochemical values were normal as fasting glucose and thyroid functions. We performed a diet, suggested her to chew food while eating, drinking at least 2 liters of water per a day and walking at least 120 minutes per week. She called for controls to be weighed at intervals of 15 days to our family medicine clinic. Patient was motivated to be weakened and reminded recommendations on each visit. Patient was satisfied with the diet program and loses weight without starving. She lost about 2 kilos in measurements every 15 days. The patient weighed 89.3 kg at the end of 3.5 months and fat ratio measured as 39.8%.

CONCLUSIONS: Applying diet program in family medicine clinic, making checks in 15 days and motivation during the controls helped patient to lose weight. As a result, our patient lost 15 kilos at 3.5 months. This shows effectiveness of regular follow-up and motivation. In this respect, family physicians who can give continuous care has an important role in the fight against obesity.

The Study of The Presence Of Depression Among The Employees Of Medical Centre 'Zitishte'

Tamara Draskovic¹, Anelya Roshu², Xenia Pantic¹

¹medical centre zitishte, emergency unit

²medical centre zitishte, general practice

The INTRODUCTION:

The depression is a common mental disease which can be described as being in a sad mood with loss of interest and satisfaction, lack of energy, the sense of guilt and low self – esteem, eating or sleeping disorders, problems with concentration. These problems can be chronic or repetitive and prevent a subject from executing his duties on a daily basis.

The OBJECTIVE:

The aim of this study is to determine the frequency of the state of depression among the employees and to examine the relations between depression and stress and the presence of somatic disorders.

METHOD:

This research was conducted from 11/1/2014 till 4/1/2015 at Medical Centre 'Zitiste'. Using the method of the random choice we included 100 employees from different Medical Centre departments, 51 female and 49 male subjects. Beck's depression inventory has been used in this research. We have gathered the data based on gender, education and years of the employment. The statistics has been done by X2 tests to estimate the significance of the gained results.

RESULTS:

The presence of different states of depression has been found with 38/100 subjects. The rest of 62 subjects showed normal state of humor. We can conclude that the majority of our subjects are in a good, positive mood. We have noted that there is a considerable link between depression and the years of service as we have

perceived that the women suffer from depression more. This survey is anonymous, therefore we can not determine if depression is connected to a working place.

CONCLUSION:

It is very important to identify the symptoms of depression in time and start the treatment as soon as possible, for this is the best way to prevent the grave consequences depression can lead to.

Key words: Depression, humor, Beck's inventory

Applying personalised medicine to healthcare: raising awareness, preventing and treating diseases

Helene Alavere

Estonian Genome Center, University of Tartu

Effective treatment of hypertension is an important part of preventing many cardiovascular diseases. Effective treatment requires good medication adherence. Information about personal genetic risks gives the subject the opportunity to consciously participate in the decision making process of the treatment, including making the decisions that are realized through compliance.

The Estonian Genome Center, University of Tartu (EGCUT) is ready to provide the physicians and subjects with the information about personal genetic risks of cardiovascular diseases. However, before finalising the development of the information providing service, it is essential to study the effect of providing individual genetic feedback on medication adherence, health behaviour and treatment effectiveness in ambulatory medical practice of hypertension. The information which shall be collected during the study is about the acceptability of providing and receiving genetic feedback and it is important in developing the marketing strategies for the service. So far, there has been little research on the association between the feedback on personal genetic risks and medication adherence. That is why the planned study has the potential to significantly contribute to the international scientific discourse concerning personalised medicine.

The general objective of the study is to evaluate the applicability of personalised medicine (providing individual feedback about genetic risks) in ambulatory medical practice of hypertension.

Sub-objectives are to evaluate the effect of providing individual feedback about genetic risks on medication adherence (the primary outcome); and to evaluate the effect of providing individual feedback about genetic risks on treatment effectiveness of hypertension and health behaviour (the secondary outcomes).

The participants will be recruited at family practices in Estonia.

Genetic analysis will be conducted at the Estonian Genome Center of the University of Tartu and the feedback about the personal genetic risks will be given by family practitioners.

Keywords: personalised medicine, genetic testing, prevention and treatment of hypertension

Associations of Physical Activity with Sleep Quality and Perceived Stress Scale Among Medical Students

Bahriye Arslan, Funda Yıldırım Baş

Department of Family Medicine, Süleyman Demirel University, Isparta, Turkey

AIM: We conducted this study to investigate the association of physical activity with sleep quality and perceived stress level among Turkish medical students.

METHODS: This study was conducted in the Faculty of Medicine at Süleyman Demirel University in Turkey. The students reported with questionnaires. The questionnaires contained questions regarding each student's age, sex, height, weight, smoking, alcohol and drug use, and disease history. Physical activity was assessed using the International Physical Activity Questionnaire (IPAQ), sleep quality was measured via the Pittsburgh Sleep Quality Index (PSQI) and perceived stress was examined using Cohen's Perceived Stress Scale (PSS). Non-normally distributed continuous variables are expressed as median and interquartile range (median [IQR25-IQR75]) and were compared with Mann-Whitney U tests. The relation between IPAQ score and PSQI and PSS scores was determined using Spearman's correlation coefficient.

RESULTS: Of the 905 students, 462 students (54.2%) were female. The age of participants ranged from 18-28 and the mean age was 20.73±1.9. Participants were classified according to their IPAQ scores; some 256 (30%) students were physically inactive. On the other hand, when classified according to their PSQI global score, 392 (46%) students had a poor sleep quality. There was a strong correlation between IPAQ score and PSQI and PSS scores. Physically active students had significantly higher levels of sleep satisfaction and lower levels of stress. Similarly, the PSS score was well correlated with the PSQI score. Students with low levels of stress were more likely to express satisfaction with their sleep

CONCLUSION: The results of the present study indicate that an increased PA level is associated with higher quality sleep and decreased perceived stress levels.

Subclinical hypothyroidism and psychiatric symptoms

Patricia Elena Oscanoa¹, Max Alexander Encarnación¹, Marta Bandrés², Susana Elisabeth Riesgo², Nerea Trecet¹, José Romero²

¹CAP Amadeu Torner

²ABS Santa Eulalia Sud

Background & AIM:

To determine the prevalence of anxiety and depression in patients with a previous diagnosis of subclinical hypothyroidism (SH) using Goldberg and Beck anxiety and depression inventory, and the therapeutic management.

METHOD:

A cross-sectional study was conducted in an urban primary care center in January and February 2015. All patients ≥ 18 years diagnosed with SH without previous diagnosis of anxiety or depression or cognitive impairment were included, recorded in the medical record. Of 673 patients with SH, 187 randomly selected were administered: 161 Goldberg inventory (patients without anxiety or depression after SH) and 26 Beck inventory (those with anxiety or depression after HS to assess the current intensity of symptoms). Statistical analysis was conducted in SPSS.

RESULTS:

N = 187, 77.5% women, mean age: 57.48 years (SD: 16.7), 65.2% were married, 26.7% with secondary education, occupationally active 35.8% and 92.5% were Spanish.

44.4% had arterial hypertension, 2.7% atrial fibrillation, 10.7% diabetes mellitus 2, 58.3% dyslipidemia and 22.5% obesity.

The average duration of SH was 5.6 years (SD: 4.8). Of the sample, 34.8% received thyroid hormone, 15% anxiolytics and 12.8% antidepressants.

Regarding Goldberg inventory, 26.7% were positive for anxiety (CI: 19.9%-33.5%, $p < 0.05$) and 33.5% for depression (IC: 26.2%-40.8%, $p < 0.05$).

CONCLUSIONS:

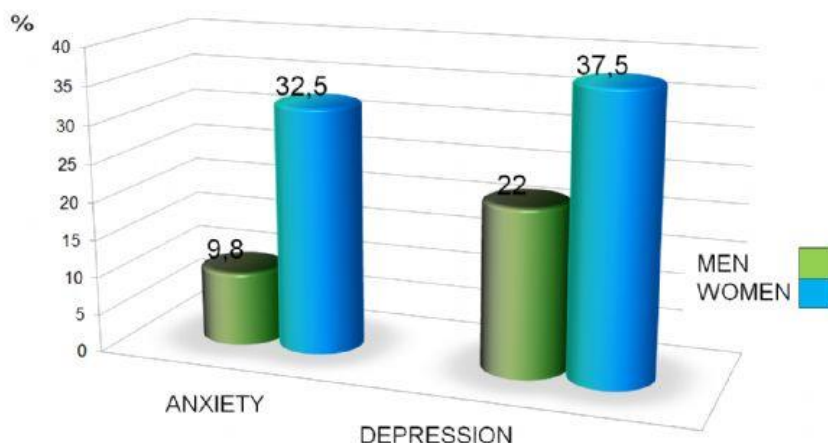

In this study, SH is associated with anxiety and depression. We found a high prevalence of both with Goldberg inventory, for what we think we should follow up on patients with SH if present these pathologies and perform appropriate management with antidepressant and psychological treatment. Consideration should be given to start thyroid hormone because there are trials that guarantee an improvement in this type of patient. Also, most patients with HS have dyslipidemia and hypertension, so it is important to control cardiovascular risk factors.

Role of nurse practitioners in reducing cardiovascular risk factors: a retrospective cohort study

Zalika Klemenc-Ketis¹, Alenka Terbovc³, Bostjan Gomiscek⁴, Janko Kersnik²

¹Department of Family Medicine, Medical Faculty, University of Maribor, Maribor, Slovenia

²Department of Family Medicine, Medical Faculty, University of Ljubljana, Ljubljana, Slovenia

³Zdravstveni dom Kranj, Osnovno zdravstvo Gorenjske, Kranj, Slovenia

⁴University of Maribor, Faculty of Organizational Sciences, Kranj, Slovenia

Background and aim

A new model of 'renewed' family practice was introduced in Slovenia as a pilot project in 2011, in which nurse practitioners are included in a team carrying out preventive activities and managing patients with stable chronic diseases. In this study we wanted to determine the impact of nurse practitioners' counselling on reducing cardiovascular risk factors in patients participating in routine preventive check-ups.

Method

This retrospective cohort study was conducted in 16 family medicine practices (eight renewed and eight regular family practices). In each family practice, a systematic sample was selected of registered patients participating in cardiovascular preventive check-up. Data on sex, age, blood pressure value, cholesterol value, blood sugar value, smoking, level of physical activity, and cardiovascular risk were collected. Patients attending renewed family practices received counselling on risk factors from nurse practitioners (test group), and patients attending regular family practices received the counselling from family physicians (control group). Data were collected again at least one and no more than five years after the baseline consultation. This study was a part of CPC+ (Upgraded Comprehensive Patient Care).

Results

There were 128 patients in the test group and 129 patients in the control group. At the control visit, the patients counselled by nurse practitioners had significantly lower levels of systolic blood pressure and cholesterol and practiced regular physical activity significantly more often than patients counselled by family physicians.

Conclusion

Nurse practitioners can be successful when counselling patients on cardiovascular risk factors during their preventive check-ups.

⁸Medicina Familiar y Comunitaria. Unidad de Vigilancia de la Salud. Unión de Mutuas. Castellón, España

OBJECTIVE: To know the opinion of sanitary professionals working at the Primary Health Care Centers (PCHc) about the potential role of Community Pharmacy Offices (cPhO) in the management of blood pressure (BP).
Design and METHOD: Survey structured into 12 questions with semi closed answers was addressed to physicians (Ph) and nurses (Nr) of the 250 PCHc in the Comunitat Valenciana (CV), a region in the east coast of Spain.
RESULTS: 952 professionals answered the survey. Most participants were Ph (63.1%), females (50.8%) with 20.9±10.0 years of experience. More than 20 reasons were considered as potential advantages of cPhO for BP control compared with PCHc (Table). 3.9% of participants believed that cPhO have not any advantage. The most common answers to the question What do you think is the role of the cPhO in the management of BP? were: Easier detection of undiagnosed and/or uncontrolled hypertension (35.7%), Coordinated aid for the PCHc (30.4%), and None (18.7%). The percentage of those thinking that cPhO have not any potential role was significantly lower in Alicante (13.3 % vs. 20.2 and 20.7 % for Castellón and Valencia), without differences in gender, experience or professional collective. The majority (62.9 %) of participants thinks that the cPhO are fulfilling their role, with 3.9% saying that they Do not know. Those with a negative point of view were mainly men (34.8 vs. 28.3%) and Ph (34.9 vs. 25.0%) ($p>0.05$ for both). It was pointed 13 different reasons to think that cPhO are not fulfilling their role, mainly: Inadequate measurement methodology (24.1%), Ignorance about the disease (16.7 %), Tendency to overestimate BP values and alarm patients (16.3%), No coordination with PHCc (8.9%).
CONCLUSION: The majority of professionals working at PCHc think that cPhO has advantages for management of BP, mainly flexibility, accessibility and lower WCE.

Disability, Home Accidents And Family Medicine Role

Serkan Bayad, Vildan Mevsim

Department of Family Medicine, Dokuz Eylul University, Izmir, Turkey

Introduction

The home environment is the most essential factor for children's injuries, half of injuries happens at home. Batteries are the one of the home hazards, ingestion or insertion of batteries can occur easily and is often unnoticed. It causes several symptoms like dysphagia, fever, respiratory distress, restlessness, electrolyte leakage, pressure necrosis, metal toxicity or tissue damage by alkaline.

It is estimated that % 10 of children globally suffer from some kind of disability. Prevalence of injury among disabled children is % 4.4. We meet frequently children with home accidents in family medicine unit(FMU). For this reason we discussed in this case disabled children home accident and family physician role at management, prevention strategies.

Case presentation

Intellectual disabled 5 y children was brought to FMU, insert remote control battery from rectal way. Parents has noticed but lately. Battery was palpable on examination and removed. It was bitten and found openings around. We called Poison information Center(PIC). The patient was sent to emergency service(ES) because of PIC recommendation, another battery ingestion or insertion suspect and absence of radiograph. At ES, nothing detected on X-ray. Patient was monitored. In follow-up process no symptom was detected. Possible situations was told and patient discharged. Patient was taken to our follow-up again. Any pathological condition didn't reveal. Information was given the family about home accidents. A security list was created. PIC, ES and FMU numbers were taught.

Conclusion

The most effective management strategy at home accidents is prevention. Family physicians should know management and prevention for home accidents. Their position is very important because of relatives with patients. Home care service is an opportunity for patients and physicians. Also other health care professionals should be responsible. For detailed prevention programmes, state policies should be created and media support is necessary.

²USF Famílias, ACeS Entre Douro e Vouga, Santa Maria da Feira, Portugal

Background & AIM: Basal cell carcinoma (BCC) is the most common skin cancer and its incidence varies depending on the predominant skin type in a given population and sun exposure habits, standing in Portugal close to 100 new cases per year per 100,000 inhabitants. Nodular BCC is the most common subtype. Clinically, lesions appear as pink papules with raised edges and pearly or pigmented appearance. The prognosis of BCC has improved substantially in recent decades, due to earlier diagnosis and surgery with fewer sequels. The aim of this clinical case is to show the efficacy and advantages of digital referencing of dermatological cases.

METHODS: Direct interview, clinical data query in the Portuguese health data platform.

RESULTS: Male, 62 years old, no toxic habits. Past medical history: hypertension, dyslipidemia. Regular medication: aspirin 150 mg id, simvastatin 20 mg id, (amlodipine 5 mg + 20 mg olmesartan) id. History of present illness: patient comes to family doctor office with burning sensation around a lesion on the back with 2-3 months of evolution. Physical examination revealed a pigmented lesion of the dorsal region of about 10mm long axis. Patient was referred to the dermatology consultation at reference hospital through P1 Alert® system with two pictures attached. One month and 17 days later, nevus excision was done having the histological examination showed a correspondence to BCC of nodular type.

CONCLUSIONS: Digital-referencing with image in dermatology allows prioritizing urgent situations, facilitating the screening and evaluation of patients with limited access to secondary health care. Although with limitations, these storage and image transmission systems provide high levels of diagnostic accuracy, are beneficial in terms of cost and are more convenient for primary care health professionals, as for patients as well.

Before the onset of psychosis – empowering family doctors

Sofia Correia Pinto¹, Joana Carneiro², Oriana Correia Pinto³, Inês Domingues Teixeira⁴

¹USF S. João do Porto, Porto, Portugal

²USF Garcia da Horta, Porto, Portugal

³Serviço de Psiquiatria, Centro Hospitalar Vila Nova de Gaia, Porto, Portugal

⁴USF Ribeira Nova, Lisbon, Portugal

Background & AIM:

About 15% of the general population experience auditory hallucinations and 15-20% paranoid thoughts. On average 2 to 3% of the adult population will develop overt psychosis and 6% subthreshold psychosis. Some individuals are “at risk mental state” (ARMS) of developing this condition, 18% of which will develop psychosis at six months and 36% at three years.

Early intervention has earned increasing interest and it has been shown that it can prevent or delay the onset of psychosis, or at least diminish the duration of untreated psychosis, ultimately improving outcomes.

We aim on increasing family doctors’ knowledge of early warning signs for psychotic disorders and suggest a protocol on adequate management of individuals who are ARMS of developing psychosis.

METHODS:

Literature review of selected articles and books deemed relevant by the authors, using Medline/Pubmed database with the combination of the following key-words: “psychosis”, “primary health care”, “prevention”.

RESULTS:

The onset of psychosis usually occurs in individuals at 16 to 30 years of age. Specific criteria have been established to identify the people who are ARMS of developing overt psychosis. Regular monitoring, psychotherapy or in some cases pharmacotherapy should be offered to individuals in this group.

CONCLUSION:

Family doctors have a multi-dimensional view of the patient and can provide a low stigma environment in which to assess and treat patients with psychiatric disorders. They play a crucial role in creating awareness about signs and symptoms suggestive of ARMS or overt psychosis, identifying them at a very early stage and preventing any delays in treatment.

A close working relationship between specialist mental health services and primary care is essential.

P-0670**An evaluation of the awareness and attitudes towards life style changes in a group of hyperlipidemic patients**

Merve Esen Arslan, Işık Gönenc, Emine Zeynep Tuzcular Vural, Refik Demirtunç
Haydarpaşa Numune Training and Research Hospital

Background and AIM: In this cross-sectional study evaluation of knowledge levels related to hyperlipidemia(HL), life style changes(LSC) and complications of HL and behavioral characteristics of LSC in hyperlipidemic patients was aimed.

METHOD: A questionnaire composed of 31 questions inquiring the knowledge and awareness of LSC in hyperlipidemic patients was used to obtain data from 302 hyperlipidemic patients.

RESULTS: The mean age of participant was 50.6±13.2 years, 73.8 % was women, 35.8% had primary educating. 28.5 % of the participants were recently diagnosed with HL, 59.6% had a positive family history and 30.8 % were using drugs for HL.53.3% was obese. Although 229 of the patients said cholesterol levels decrease with weight loss, 38.9%of these patients hadn't tried to lose any weight. 50.5% of participants who said overweight people had high cholesterol levels, was obese. 55.3 % of patients who said daily 30 minutes of physical activity is necessary, didn't do any physical activity. 26.8 % of participants who knew reducing daily fat intake would decrease cholesterol, didn't make any dietary changes. 44.0% of patients who knew alcohol raised cholesterol levels, quit alcohol after the diagnosis. 47.4% of aware of smoking worsening hyperlipidemia, has quit smoking. Increased risk of myocardial infarction is most well-known complication of the HL by 80.5%. Male sex, age over 55, higher level of education and income, family history, HL medication usage were statistically significantly related with high knowledge scores. Female sex, Women, age over 55, low levels of education and income, using medication for additional diseases, former diagnosis of HL, non-smoking and no alcohol, obesity statistically significantly increased HL behavior scores.

CONCLUSION: CVD deaths has become the number one cause of death all over the world. LSC has an important role for preventing and treatment of CVD in the primary care.

⁴Department of Orthopaedic Surgery, Medical School, Democritus University of Thrace, Alexandroupolis, Greece

⁵University hospital of Alexandroupolis, Greece

⁶Laboratory of Medical Statistics, Medical School, Democritus University of Thrace, Alexandroupolis, Greece

Background & Aim. The purpose of this study is to investigate the influence of systematic training in physical growth and biological maturity in prepubertal males.

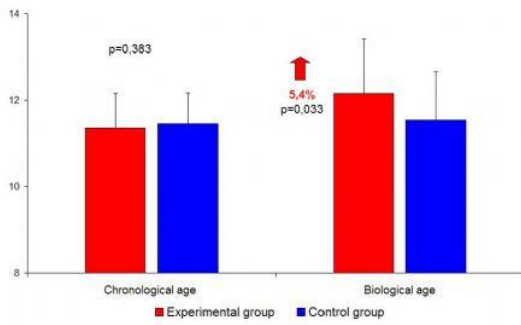

Method. The sample consisted of 177 pupils in fifth and sixth grade of primary school in the city of Alexandroupolis, who participated voluntarily. Physical activity levels were estimated with questionnaires. Subjects were subdivided into "control group" (prepubertal, whose only physical activity was the physical education of school and they never participate in systematic training, n=95) and "experimental group" (prepubertal, whose the weekly physical activity included, physical education in their schools and additionally 3-4 training units organized training in various sports clubs in the city, n=82). The following parameters were recorded: the biological age, measured by determination of skeletal age; bone density, measured by ultrasound methods; anthropometric and morphological features, such as height, body composition, selected diameters, circumferences and skinfolds; motor ability tests (Astrand's test, speed shuttle run test, vertical and horizontal jump, handgrip strength test, sit and reach test, sit ups, hanging with bent elbows, pulls at horizontal bar). **Results.** It was found that the "experimental group" exhibited older biological age (12.15 ± 1.26 years vs 11.53 ± 1.13 years, $p=0.033$), higher bone density (by 6.7%, $p<0.001$), lower BMI and body fat (by 7.7% and 14.0%, respectively; both $p<0.001$), better anthropometric features and higher performance throughout all motor ability tests ($p<0.05$), compared to "control group".

Conclusions. The present study demonstrated that the systematic physical activity has a positive effect on both the physical and the biological maturity of pre-pubertal children. This effect is mainly expressed through strengthening bone due to the increased bone density and the improvement of kinetic skills of pupils who participate in organized extracurricular sport-activities.

Hyperemesis Gravidarum

Ebru Kender

Department of Family Practitioners University of Medeniyet Göztepe Education and Research Hospital, İstanbul, Turkey

Nausea and vomiting are early and common signs most frequently seen in pregnancy. These symptoms can start in the first trimester and can last until the end of pregnancy and can be seen among %75 of pregnant women. Hyperemesis gravidarum (HG) is a severe form of nausea and vomiting seen in pregnancy, usually described with dehydration, malnutrition and at least %5 loss of the total body weight. The prevalence can change between %0.3 and %2. It is reported that in HG there can be electrolyde and acid-base imbalance, anemia, ketonuria and neurological signs like lethargy and these patients usually need internation. HG influence not only the physical but also mental status and life quality of the pregnant women and cause loss of functionality. Aldought the etiology and pathogenesis of HG has not been clear yet, it is suggested that endocrine and psychological factors are having a role.

In literature it is reported that there can be a relation between HG and psychological illnesses. Studies reveal that HG diagnosed patients have much more mental problems comparing with the control group. It is found out that in patients diagnosed with HG the level of depression and anxiety is higher that the healty pregnant women, pregnants diagnosed with HG show up much more with major depression, anxiety disorder and some personal disorders. Pregnancy is a period where there are worries about the changing body shape and weight and it is proposed that pregnants with eating disorders can hardly tolerate this period. In our study it is aimed to identify the social, demographic and clinic status of patients diagnosed with HG who are hospitalised in women health and birth clinic and also research their eating attitudes and their level of anxiety and depression.

Vaccination rates of geriatric population: a cross-sectional investigation from Antalya

Ramazan Vural¹, Suzan Yazıcı², Mehmet Özen¹, Hasan Kurşun¹

¹Family Practice Clinic, Antalya Training and Research Hospital, Antalya, Turkey

²Department of Gerontology, Akdeniz University, Antalya, Turkey

BACKGROUND& AIM: The weaker immune system, decreased immune response to vaccinations and a higher incidence of complications from infectious diseases in old age are among factors why vaccination in old age is on the agenda. Pneumococcus, influenza, herpes zoster and tetanus are vaccinations advised for the older population. The aim of the research is to evaluate the vaccination rate of the population 60 years and older and to discuss vaccination at old age.

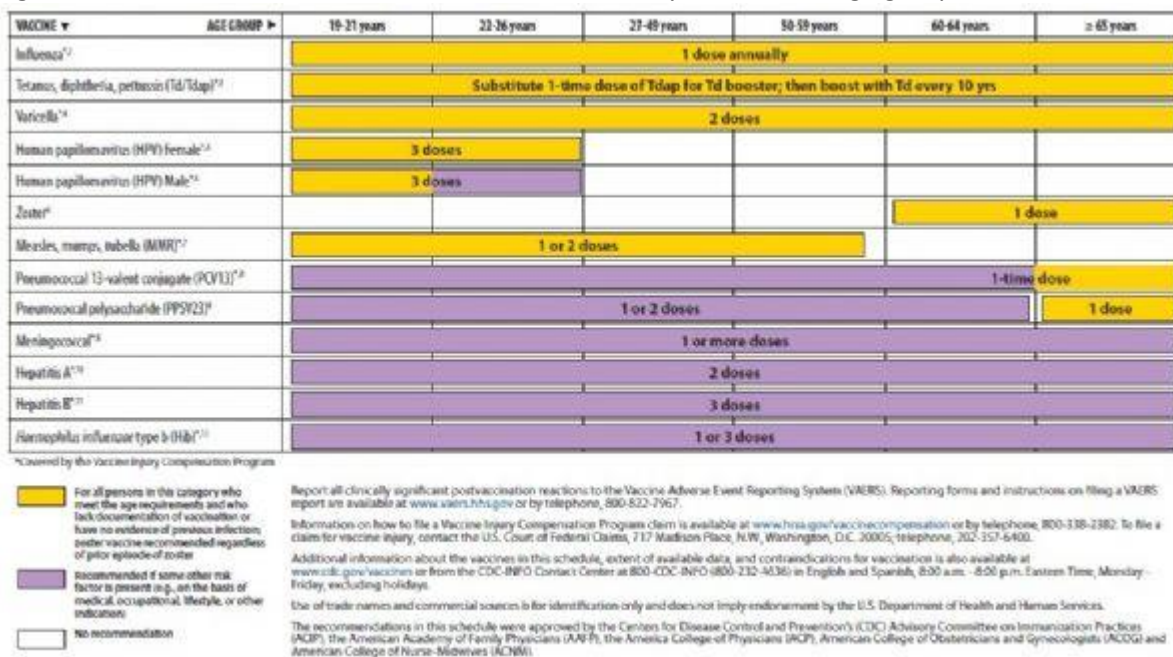

METHOD: The descriptive, cross-sectional and prospective research is using quantitative methodology. 298 persons over the age of 60, who were attending Antalya Training and Research Hospital Family Practice Clinic between December 2013 and February 2014 have been interviewed. Data is analyzed using SPSS software program.

RESULTS: 54% of the respondents were women, and 46% were men. The average age was 69.1. 234 of the respondents were under the age of 75 whereby 64 were 75 years and older. 38.6% of the respondents were vaccinated against Influenza, 10.7% against tetanus and 8.1% against pneumococcus. No correlation has been found between vaccination percentage and education, gender and age. Statistically no significant difference was found for the vaccination rates between the age groups under 75 and 75 and older.

CONCLUSIONS: The vaccination rates for the older population was found to be under the target levels. The rates could be increased sensitizing by informing the older population about vaccination by the health care staff. A higher level of vaccination could enable the society to become immunized.

Colorectal cancer screening knowledge, attitudes, and practices of family physicians in Samsun, Turkey

Mustafa Kürşat Şahin, Servet Aker

Canik Community Health Center, Samsun, Turkey

Background &AIM: “Colorectal cancer (CRC), which ranks third in cancer morbidity and second in cancer deaths worldwide, can be detected early and prevented with mass screening programs. Family physicians (FP) have a key role in screening practice due to frequent contact with large proportion of population. The aim of our study is to explore the current knowledge, attitude and practice of family physicians toward CRC screening and to identify the barriers of conducting such a screening.

METHOD: A cross-sectional descriptive study was carried out among FP working in family health center in Samsun, Turkey. Self-administered questionnaires which consisted of demographic data, qualification, background on the primary care clinic, practices on colorectal cancer screening and barriers to CRC screening were distributed. Data were analyzed using SPSS 22.0 package program. In the analysis, frequency and percentage from descriptive criteria were used.

RESULTS: The study included 251 FP. There were 87 (34.7%) female and 164 (65.3%) male physicians. The average age of FP were 43.37 ± 6.66 year, average working experience of FP were 18.52 ± 6.57 year, average number of a patients seen per day were 60.47 ± 19.59 . One hundred sixty four (65.3%) physician didn't follow any guideline. Two hundred (79.7%) physician order screening test but half of physicians didn't know correct timing when screening began and stopped. Only 83 (33.1%) FP ordered fecal occult blood test correct frequency and 31 (12.4%) FP recommended colonoscopy every 10 year. The most common barrier stated by FP was “patient refusal”

CONCLUSIONS: This study indicates that CRC preventive activities among primary health care provider is still poor in Samsun, Turkey. Knowledge gaps about the timing and frequency of screening and suboptimal screening delivery were evident.

Keywords: colorectal cancer, screening, family physician, fecal occult blood test, colonoscopy.

P-0675**Prostate cancer screening knowledge, attitudes, and practices of family physicians in Samsun, Turkey**

Mustafa Kürşat Şahin, Servet Aker

Canik Community Health Center, Samsun, Turkey

Background &AIM: The prostate cancer is the second most common cancer worldwide for males, and the fifth most common cancer overall. The aim of this study was to evaluate family physicians' knowledge, attitudes and practice related to prostate cancer screening.

METHOD: A cross-sectional descriptive study was carried out among family physicians (FP) working in family health center in Samsun, Turkey. Self-administered questionnaires which consisted of demographic data, qualification, background on the primary care clinic, practices on prostate cancer screening and barriers to prostate cancer screening were distributed. Data were analyzed using SPSS 22.0 package program. In the analysis, frequency and percentage from descriptive criteria were used.

RESULTS: The study included 244 family physicians. There were 85 (34.8%) female and 159 (65.2%) male physicians. The average age of FP were 43.39 ± 6.74 year, average working experience of FP were 18.54 ± 6.61 year, average number of a patients seen per day were 60.45 ± 19.48 . One hundred thirty three (44.4%) family physicians did not do prostate cancer screening. Almost all didn't follow any guidelines. Hundred fifty three (62.7%) physician order only prostate specific antigen (PSA) and 182 (81.3%) of physicians felt screening was effective. Physicians' most common cause to order PSA was suspicious to prostate enlargement clinical symptoms.

CONCLUSIONS: Prostate specific antigen screening for prostate cancer screening is not uniformly recommended by national organizations or primary care physicians (PCPs). But physician use PSA as a cancer screening tool and didn't follow any guideline. Training may be prepare for family physician related prostate cancer screening.

Keywords: prostate cancer, screening, family physician, prostate specific antigen

P-0676**Cervical cancer screening knowledge, attitudes, and practices of primary health care workers in Samsun, Turkey**

Mustafa Kürşat Şahin, Servet Aker

Canik Community Health Center, Samsun, Turkey

Background &AIM: Cervical cancer is one of the ten most frequent cancers in Turkey. Early diagnosis and treatment is crucial for decreasing the mortality rate in the cervical cancer. The aim of this study was to evaluate of primary health care workers' knowledge, attitudes and practice related to cervix cancer screening.

METHOD: A cross-sectional descriptive study was carried out among primary health care workers (PHCW) working in family health center in Samsun, Turkey. Data were collected by the researcher, applying face-to face structured interview techniques with a questionnaire developed after a relevant literature review. Data were analyzed using SPSS 22.0 package program. In the analysis, frequency and percentage from descriptive criteria were used.

RESULTS: There were 84 (35.3%) nurse, 145 (60.9%) midwife and 9 (3.8%) others. The average age of PHCW was 35.37 ± 6.60 year. Most of them (85%) were married, but only half of PHCW have done pap-smear. 190 (81.2%) of PHCW had heard HPV vaccine, but only 37 (16.7%) of them had known correct dosage. Only three percentage (n: 7) of participant ha heard Kato's self-scraping pap-smear device and 177 (76%) of workers desired to use Kato's device. Nurses and midwives knowledge about cervical cancer was limited.

CONCLUSIONS: Half of PHCW in our population had never had a Pap smear and wanted to use the Kato's device. Training programs can be prepared about cervical cancer for PHCW.

Keywords: cervical cancer, screening, family physician, pap-smear, HPV vaccine

Breast cancer screening knowledge, attitudes, and practices of primary health care workers in Samsun, Turkey

Mustafa Kürşat Şahin, Servet Aker

Canik Community Health Center, Samsun, Turkey

Background & AIM: Breast cancer is the most common cancer seen in women, both in developed and also in developing countries, and ranks first in mortalities from cancer. The aim of this study was to evaluate of primary health care workers' (PHCW) knowledge, attitudes and practice related to breast cancer screening.

METHOD: A cross-sectional descriptive study was carried out among PHCW working in family health center in Samsun, Turkey. Data were collected by the researcher, applying face-to-face structured interview techniques with a questionnaire developed after a relevant literature review. Data were analyzed using SPSS 22.0 package program. In the analysis, frequency and percentage from descriptive criteria were used.

RESULTS: Total 228 PHCW participated our study. There were 80 (35.1%) nurse, 139 (61%) midwife. The average age of PHCW was 35.43 ± 6.62 year. 195 (85.5%) of them were married. The prevalence of breast self-examination was 82.9% (n: 189), breast clinical examination was 30.7% (n: 70) and mammogram was 18.4% (n: 42). Fifty (24.1%) of PHCW had heard BRCA1-2 gene mutation test. Nurses and midwives knowledge about breast cancer was limited.

CONCLUSIONS: Health professionals are a direct source of medical information to the public. The use of breast clinical examination and mammography was found lower than expected when considering the fact that participants were health care Professional. Health education programs are essential to encourage and improve PHCWs' practice of breast cancer screening.

Keywords: breast cancer, screening, family physician, breast self examination, mammogram

The Turkish Validity and Reliability of Desicinal Balance Scale

Tugba Onat, Dilek Guldal

Department of Family Medicine, Dokuz Eylul University, Izmir, Turkey

Background: There are different types of treatments about obesity like medical, surgery, diets, physical activity. Models for behaviour changes are become popular and studied all over the world. The Transtheoretical Model is a paradigm for behavior change in individuals and is the theory that guided this project. It has been used as a method to determine individuals' readiness to change behaviors. The constructs or framework of the TM include: the Stages of Change, Self-efficacy, Decisional Balance, and Processes of Change. We realised that there is no turkish version of the desicinal balance scale. And we decided to establish the Turkish validity and reliability of desicinal balance scale, validity and reliability of which was proven and used the most frequently among the scales that assess TTM.

METHODS: The design of this study was methodological translation and re-translation is performed. After face and content validity cigarette used for criterion validity.

Test-retest, Split-half, Cronhbach-alfa used for reability.

Analysis of data was performed in SPSS 15.0 program

RESULTS: 100 participants who are obes and cigarett smokers were participated the study. Obesity decisional balance scale total score and smoking cigarette decisional balance scale total score correlation was $r=0.289$ $p=0.017$. For the internal reability Cronbach-alfa was 0.715.

For the test re-test was applied to 30 participants and test re-test correlation was $r=0.978$ $p=0.00$.

Conculisition: these results revield that desicinal balance scale is valid and reliabile in Turkish language.

Stroke: People can recognize the symptoms and come to the health center at the right time ?

Hector Leonardo Lugo Ramos, Rocio Lobato Martinez, Jose Maria Fernandez Gonzalez
Hospital Jerez de la Frontera - Cadiz

OBJETIVES

To assess the degree of information and knowledge of the people against stroke as common pathology in our environment. Assess the degree of education in recognizing symptoms, initial acting or therapy against stroke.

METHODS

Survey written and/or directed telephone about stroke in patients who went to a health center or a hospital emergency room, regardless of the reason for your request. The survey asks about sex, age, warning signs of stroke and to conduct take.

RESULTS

A total sample of 154 patients, found that 31% of respondents do not know the warning signs for stroke (similar results with both sexes with an average age of 53.5 years old). Of those who did know recognize 5% administer

any medication(antihypertensive, antiplatelet). 48% emergency call, 42% would go directly to the hospital, 7% expect at home to see if symptoms were improved and the remaining 3 % would go to the nearest health center.

CONCLUSIONS

Despite the many education campaigns and development of information held among the public, stroke remains a disease whose initial symptoms are not widely recognized by the population. By contrast, the user does know detect symptoms also knows he must act quickly to optimize the treatment of this disease. That is why we must continue working on all levels, mainly from primary care in patient education to comprehensive care effectively start within the first hours after a stroke.

Use of inhibitors of the dipeptidyl-peptidase-4 (idpp-4) in diabetic patients in primary care

Jose María Fernandez Gonzalez¹, Hector Leonardo Lugo Ramos¹, Inmaculada Saucó Colon²

¹HEALTH CENTER OF LA GRANJA-MANUEL BLANCO, HOSPITAL OF JEREZ DE LA FRONTERA.

²HEALTH CENTER OF SAN BENITO, HOSPITAL OF JEREZ DE LA FRONTERA.

OBJECTIVE

To evaluate the use of inhibitors of the dipeptidyl-peptidase-4 (IDPP-4) in diabetic patients in primary care and its impact on the reduction of glycosylated hemoglobin.

MATERIAL AND METHODS

Cross-sectional study using data collection of the medical history. Were selected to all diabetics of a urban health center take IDPP-4, either alone or associated with other antidiabetic agents, excluding 10 due to lack of registration of the glycosylated hemoglobin.

RESULTS

Were selected 326 diabetic patients, of whom 52.1 % were male and 47.9 % women. The mean age was 66.6±11.5 years. The 84% also took metformin, sulfonylureas 25.8 per cent, 4.3 per cent glinidas, the 1.5 % thiazolidinediones, the 0.6 % inhibitors of the alpha-glucosidase inhibitors, and the 21.5 % insulin. Of the IDPP-4, 60.7 % were taking sitagliptin, the 32.5 % vildagliptina, the 3.7 % linagliptina, and 3.1 % saxagliptina. The average

number of glycosylated hemoglobin before treatment with IDPP-4 more metformin was 8.1 ± 0.9 and the current 7.7 ± 1.2 , with an average reduction of glycosylated hemoglobin of 0.32 (95% CI: 0.16 -0.49, $p=0.06$), being less than the reduction in the IDPP-4 associated with other antidiabetic agents (0.09, 95% CI: 0.07 -0.12, $p>0.08$). These results are somewhat lower than those described in clinical (reduction of around 0.40 % -1.05% of glycosylated hemoglobin. The time of treatment with IDPP-4 was less than 1 year in the 33.8 %, 1-2 years in 36.9 %, 2-3 years in 24.6 % and more than 3 years at 4.7 %, no differences were found between the groups.

CONCLUSION

The use of IDPP-4 associated with metformin decreases a 0.32 average in the glycosylated hemoglobin, although this result is not statistically significant. More studies are needed to obtain findings with greater reliability.

Retinography in primary care

Jose María Fernandez Gonzalez¹, Hector Leonardo Lugo Ramos¹, Pedro Guijo Gonzalez²

¹HEALTH CENTER OF LA GRANJA-MANUEL BLANCO, HOSPITAL OF JEREZ DE LA FRONTERA.

²INTENSIVE CARE UNIT HOSPITAL OF JEREZ DE LA FRONTERA

OBJECTIVE

To determine the usefulness of the Primary Care retinography interpreted by family doctor as a tool in early diagnosis of glaucoma.

MATERIAL AND METHODS

Study made in Primary Health Care in collaboration with specialized care, with $n=196$ (comprehensive study conducted in 194 patients; losses: 2 (not came to perform the tests),

Sectional and descriptive study with assessment by two observers in parallel, comparing interpretation by family physicians in color fundus photographs made in Primary Care with the study of ophthalmologists.

Inclusion criteria: diabetics, between 40-70 years and hypertensive; of exclusion: does not meet the previous, diagnosis of known Glaucoma and/or non-availability of retinography assessable.

Dependent variable: diagnosis of chronic glaucoma (qualitative and dichotomous nominal); independent: excavation papillary, age, sex. Validity of the test from sensitivity, specificity, interobserver concordance (index Kappa and quotient correlation), positive and negative predictive values, positive likelihood ratio and negative, calculated by SPSS 15.0.

Possible limitations: lack of specific computing tools of measurement papillary, small sample, evolutionary nature of glaucoma, low prevalence of glaucoma.

RESULTS

Of n=194: 91 females and 103 males. Incidence of glaucoma of 3 %, intraclass correlation coefficient and kappa index moderate, with higher interobserver correlation for assessable qualitative quantitative, high specificity (right eye OD= 93 %, left eye OI=93.1 %), negative predictive value (OD 93.5 %, OI 97 %) and positive likelihood ratio (OD 3.05;OI 5.35), good for screening tests; low sensitivity (OD21.4 %;OI37,5 %), positive predictive value (OD and OI20 %) and negative probability quotient (OD 0.8;OI0,67).

Conclusion

Retinography may be a good tool for screening for glaucoma by being very specific with positive probability quotient high and low false-negative rate.

An Irritant Contact Dermatitis Caused By Buttercup: A Case Report

Selman Erturhan¹, Ali Ramazan Benli², Muhammet Ali Oruç³, Senay Demir Yazıcı⁴, Hilal Ozkaya⁵

¹Altinyayla Hospital, Altinyayla, Sivas, Turkey

²Department of Family Medicine, Medical Faculty, Karabuk University, Karabuk, Turkey

³Turkish Medicines and Medical Devices Agency, Ankara, Turkey

⁴Department of Physical Examination and Rehabilitation, KBU Karabuk Education and Research Hospital, Karabuk, Turkey

⁵Department of Family Medicine, IBB Darulaceze Nursing Home, Kayisdagi, Atasehir, Istanbul

A 69 years old woman applied our policlinic because of the wounds in her both legs. The patient was asked how those injuries happened. The patient had had knee pain for a long time and the pain killers didn't help her, so she applied some buttercup which she grinded with a method which she had learned from her mother on her legs and covered them with pieces of muslin a day ago. When she uncovered her legs after an hour, she realized the injuries on her legs. According to the results of physical examination of the patient, all of the vital symptoms were stable, lab findings were also normal except for the level of plasma glucose and triglyceride. She was under the treatment of hipertansion and hyperlipidemia. There was a swollen erythema plague on her right leg and there was a erythema plague whose edges were livid and upside was yellow. Wounds were cured with topical fusidic acid treatment for 2 weeks and fomentation was done every day. When we asked the patient if the treatment which she had applied helped her knee pains or not, her answer was 'a little bit'.

The samples of the plant which was supplied from the patient were defined as *Ranunculus illyricus* L. Many people use plants like Ranunculaceae family as traditional treatments. *Ranunculus* (buttercup) is named in Sivas and in Turkey as 'dügün çiçeği'. Ranunculaceae contains the lactoneranunculin, and when fresh plants are bruised, ranunculin is converted to the irritant protoanemonin.

In conclusion, plants applied to the skin may show positive effects on some dermatological and rheumatic diseases, but they may also have many adverse effects. Anamnesis should include informations about alternative treatment methods.

Keywords: Buttercup, Contact Dermatitis, Ranunculin

Adherence to Medications for Tobacco Dependence Factors Associated with Discontinuation of Bupropion and Varenicline

Selman Erturhan¹, Ali Ramazan Benli², Muhammet Ali Oruç³, Pınar Kalpakçı⁴, Mustafa Cortuk⁵, Yeltekin Demirel⁴

¹Altinyayla Hospital, Altinyayla, Sivas, Turkey

²Department of Family Medicine, Medical Faculty, Karabuk University, Karabuk, Turkey

³Turkish Medicines and Medical Devices Agency, Ankara, Turkey

⁴Department of Family Medicine, Medical Faculty, Cumhuriyet University, Sivas, Turkey

⁵Department of Chest Disease, Medical Faculty, Karabuk University, Karabuk, Turkey

Background & AIM: We aim to determine the factors which affect the level of regular usage of varenicline and bupropion and the factors which affect the adherence to those two drugs, so we'll find how those situations affect the success of the treatment.

METHOD: The working group consisted of 413 university staff, who are amongst people who had applied to our 'smoking cessation clinic' between March and October in 2011. A face-to-face survey was conducted after 1-year following the day of quitting. As success criteria the oral confession of patient and exhaled carbonmonoxide(CO)<5ppm were deemed. The data was analysed by SPSS-20-software. The significance decisions were given as $p < 0,05$. According to the property of comparison, one of the following significance tests was used: independent-samples t test, paired-samples t test, Mann-Whitney U test, chi-square test.

RESULTS: 16 patients never used the drugs they had taken (3,95%). The rate of the people who used the drug ≥ 45 days was 35,7% for varenicline and %11,2 for bupropion ($p=0,000$). The patients who had used their drug ≥ 45 days were more successful. The most frequent reasons of discontinuation the medication were side effects (31,5%), feeling that they didn't need medication anymore (17,2%) and not witnessing any benefit of the drug (9.3%). The rate of interrupting the medication since the patients didn't need the drug any more was much more in the group of patients who used varenicline($p=0,005$) and the rate of interrupting the medication since the patients didn't witness any benefit of the drug was much more in the group of patients who used bupropion ($p=0,022$).

CONCLUSIONS: ≥ 45 days usage of smoking cessation drugs increases the success. Studies must be carried out to improve the patients adherence to treatment to increase smoking cessation rates.

Keywords: Tobacco Dependence, Bupropion, Varenicline

Table 1. Time Period of Drug

Time Period of Drug	Used Drug	%
Never used the drugs		3,95%
Used the drug ≥ 45 days	Varenicline	35,7%
	Bupropion	11,2%
Used the drug < 45 days		49,15%
Total		100%

Table 2. The reason for used drug < 45 days

Cause used the drug < 45 days	%
Side effects	31,5%
Feeling that they didn't need medication anymore	17,2%
Not witnessing any benefit of the drug	9.3%)
Others	42%

Family doctor - A Pillar in the Education and Trainings of Patients Suffering from Diabetes Mellitus type 2

Elizabeta Tome Bozhinovska

Private Health Facility " PZU. Dr. Beti", Bitola, Republic of Macedonia

AIM: Evaluation of the education and training of DM type 2 patients

METHODOLOGY: It was conducted a twelve month monitoring on a total of twenty-two newly diagnosed Diabetes Mellitus type 2 patients, among which, 10 of the patents were male and 12 female, at the age of 41 to 67 years. Glycolic and lipid indicators, blood pressure, BMI and abdominal fat were monitored during this research.

RESULTS: The results shown in 32% of the cases, there was a need for second anti diabetic. The troubling thing was establishing of artery-hypertension by setting up 52% diagnose on diabetes type 2. Antihypertensive therapy is recommendable in the first 6 months. In the first 6 months achieved goal values on the blood pressure only at 32% of the patients, from which the recommendation on using second anti hypertension medicine or combined therapy stems. The improvement of the lipid indicators especially on the HDL cholesterol is achieved at the end of the education and training, where the proper nutrition and the hygienic advices come in action. When it comes to the BMI (Body Mass Index) we have experienced the slowest alterations.

After 12 months we have observed slight improvement of the BMI. The results are:

- 47% had BMI up to 25 kg/m²
- 41.2% had BMI up to 29.9 kg/m²
- 11,8% had BMI up to 39,9 kg/m²
- 7% had BMI above 40 kg/m²

CONCLUSION

The family doctor plays central role in the training and education in the cases of patients with newly discovered diabetes mellitus type 2, in order to achieve better metabolic control. The aim is to motivate the patients to comply to certain diet and a life style, through which they will decrease their fat and at that way will decrease the risk from secondary complications that stem from the diabetes.

A Preliminary Study on Awareness, Perceptions and Related Factors Affecting Family Physicians' Practices on Electronic Cigarettes

Ozlem Tanriover¹, Seyhan Hidiroglu², Pinar Ay²

¹Department of Family Medicine, Yeditepe University, Faculty of Medicine, Istanbul, Turkey

²Department of Public Health, Marmara University School of Medicine, Istanbul, Turkey

Background and AIM:

Electronic cigarettes are devices that provide a battery-powered heating element to transform nicotine solution into vapour. Evidence shows the rapid increase of the popularity of e-cigarettes, although they are not FDA approved as quit smoking devices. Despite the expectation that family physicians encourage and orchestrate the smoking cessation efforts of their patients, there may be persistent uncertainty regarding the physician's precise role in managing the nicotine addicted patient. New developments in nicotine addiction and smoking cessation as with the emergence of the electronic cigarettes, add some measure of complexity to the clinician's important role in directing patients' smoking cessation efforts. In this study, our aim was to determine the family physicians knowledge, attitudes and behaviors on e-cigarettes and to clarify the factors affecting them.

METHOD:

A semistructured questionnaire consisting of 37 questions was prepared and distributed to 250 FPs. Questions mainly focused on demographic characteristics, knowledge and own use of electronic cigarettes, general attitudes against e-cigarettes, and daily practices while performing counselling on tobacco use.

RESULTS:

The mean age of the study participants was 42.1 ± 7.5 years. One-fourth of the physicians (24.1%, n=48) stated that they did not inquire about the amount of tobacco use. Moreover, 69.2% (n=137) believed that they did not receive adequate smoking cessation training. One hundred and eighty (n=88.2%) physicians have heard of electronic cigarettes and 61.2% (n=125) stated that electronic cigarettes were healthier than tobacco cigarettes and furthermore 55% (n=112) believed that risk of cancer was lower in electronic cigarettes users.

CONCLUSION:

Family physicians feel inadequate in their smoking cessation training and knowledge on electronic cigarettes. They should counsel patients based on their reported tobacco and their e-cigarette use behaviors and interests. In order to do this, family physicians should be trained about new developments in nicotine addiction and smoking cessation.

Slovenia National Programme on NCDs Prevention at Primary Healthcare

Pia Vracko, Breda Cus, Sanja Vrbovsek, Jozica Maucec Zakotnik

Center for Management of Preventive and Health Promotion Programs, National Institute of Public Health, Ljubljana, Slovenia

Background&AIM: Chronic non-communicable diseases represent a major burden of disease in Slovenia. Cardiovascular diseases are the leading cause of mortality in 2012, accounting for 39% of all deaths (men 32%, women 46%), followed by cancer (30%, men 35%, women 26%) and respiratory diseases (7,2% for both genders). Their common risk factors can be successfully addressed by support for healthy lifestyles at the primary healthcare level.

METHODS: Prevention and control of NCDs, including cardiovascular diseases, diabetes, and chronic respiratory diseases, has been carried out in Slovenia at the primary health care level since 2002 as systematic and universally accessible program. In 2011 it was upgraded to introduce registered nurses to deliver preventive services. Target population are adults above 30 years. Key components are screening for NCDs and their risk factors, and nonpharmacological support to lifestyle change, delivered by specially trained experts in 61 Health Education Centres across Slovenia. The program includes workshops for healthy weight loss, healthy diet, physical activity, quit smoking and alcohol consumption, and support in dealing with depression. The aim is to encourage individuals to actively taking care of their health, by gaining necessary skills, and by developing appropriate behavioural patterns for healthy lifestyle.

RESULTS: Over one million persons have been screened for NCDs over more than 10 years and over 350.000 people participated in program to support lifestyle change. In the last twenty years, the number of deaths from all types of CVDs halved in Slovenia. Compared to year 2000, the number of deaths from these diseases is reduced by around 1,200 annually. Since 2009, the leading cause of death in men is cancer and CVDs in women.

CONCLUSIONS: National programme on integrated NCDs prevention in Slovenia is successful at reducing the burden of NCDs, however the fraction attributable to preventive program still needs to be determined.

Keywords: non-communicable diseases, prevention, healthy life-style

P-0687**Evaluation of Blood Pressure Differences Between Both Arms of Smokers**

Gulumser Kir Dogru, [Bektas Murat Yalcin](#), Mustafa Unal
Department of Family Medicine, Ondokuz Mayıs University, Samsun, Turkey

Background & AIM: Cigarette smoking and elevated blood pressures are among the most important risk factors for CVD. Although it is recommended that blood pressure measurements should be taken at both extremities, this practice is not used routinely by many clinicians. There are accumulating data that discordance between two extremities had important clinical outcomes. The aim of this study was to investigate this difference in smokers. **METHOD:** This as a cross-sectional and retrospective study. 500 participants who admitted to the Ondokuz Mayıs University Family Medicine Smoke Cessation Clinic between June 2011 and June 2012 were included in the study. Two consecutive blood pressure measurements from both limbs were recorded in their first application. Their demographic, anthropometric measurements (BMI and waist circumference) and smoking features were also investigated. Discordance between their systolic (SBP) and diastolic blood pressure (DBP) measured in both limbs were investigated.

RESULTS: The mean right arm SBP was 111.49 ± 15.2 and DBP was 69.80 ± 11.77 mm Hg while left SBP was 109.68 ± 14.9 and DBP was 68.63 ± 11.43 mm Hg respectively. There was no difference between two limb SBP measurements in 33.2% of the participants (n = 166) however 34.2% of the participants' (n = 178) had >10 mm Hg difference between two arms. The regression analysis shown that to start smoking at an early age (<18) is an independent risk factor for difference between >10 mm Hg in SBP ($p < 0.001$, 95% CI; 0.101-0.345) and in DBP ($p = 0.002$, 95% CI; 0.101-0.345) in both arms.

CONCLUSION: We found that an important percentage of the patients had >10 mm Hg difference of blood pressure in their both arms. These patients might need more cardiovascular evaluation. Bilateral blood pressure measurement should become a routine part of the evaluation of cardiovascular examination in the primary care.

P-0688**The Compliance of the Ex-Smokers to Recommendations about Diet and Exercise**

Gulumser Kir Dogru, [Bektas Murat Yalcin](#), Mustafa Unal
Department of Family Medicine, Ondokuz Mayıs University, Samsun, Turkey

Background & AIM: Smoking is the most leading cause of the preventable deaths in the world. Many times the backbone of smoking cessation therapy and preventing recurrence depends on several life style changes including weight control. The aim of our study is to investigate the compliance of diet and exercise life styles of the smokers who underwent smoking cessation treatment.

METHOD: In order prevent weight gain after cessation every smoker received recommendations about diet and exercise (In a personalized structured session lasting at least 25 min.) as a part of their treatment (motivational interview, nicotine replacement therapy, drugs or combination of them) at Ondokuz Mayıs University Family Medicine Smoking Cessation Clinic. 460 smokers who admitted to our clinic between the dates of June 2012 to June 2013 were phoned and 335 patients who agreed to participate this study were investigated about their compliance of diet and exercise recommendations.

RESULTS: 42.4% (n=142) of the participants were female, with a mean age of 40.1 ± 9.8 years. The mean Fagerström Nicotine Dependence Test score of the participants was 5.8 ± 2.43 , with no statistical difference between genders. The male smokers had higher mean package / year of (24.1 ± 12.0) compared with female smokers (19.3 ± 11.3) ($t=3,675$, $p < 0.0001$). The cessation rate in two years was 16.1% (n= 54). Regardless of the smoking status (ex-smokers, smokers and recurrent smokers) most of the participants (n=283, 84.5%) claimed that they didn't make any increase in their physical activity or controlled their diet in two years period ($p > 0.05$). Ex-smokers weight was increased ($F=64.642$, $p < 0.001$) and they concluded that their daily calorie uptake was increased ($\chi^2=119.887$, $p < 0.001$) in this period.

CONCLUSION: Although every ex-smoker had recommendations about weight management, their weight was

increased in two years period. Ex-smokers must be screened more frequently and carefully in order to prevent weight gain.

Screening behaviours and awareness of breast, cervical and colon cancer among nurses in an urban hospital of Turkey

Ahmet Gürhan Poçan¹, Gonca Çoban², Çiğdem Gereklioğlu¹, Süheyl Asma¹, Altuğ Kut³

¹Department of Family Medicine, Baskent University School of Medicine, Adana, TURKEY

²Department of Obstetrics and Gynecology, Baskent University School of Medicine, Adana, TURKEY

³Department of Family Medicine, Baskent University School of Medicine, Ankara, TURKEY

BACKGROUND & AIM

Nurses constitute the group of health workers who can provide information to the women on cancer. The lack of a regular screening programme for and the low rate of BSE and MMG for breast cancer and pap smear for cervical cancer in Turkey led us to perform this study.

The purpose of the study was to assess knowledge, awareness and attitudes about breast, colon and cervical cancer risk factors, symptoms and screening behaviours among nurses at the university setting in a urban region of Turkey.

METHOD

The study was conducted as a cross-sectional survey among nurses working in Başkent University Adana Hospital. The survey was designed to investigate the demographic characteristics of the nurses and their knowledge on risk factors of these cancer forms and to reveal the awareness of symptoms and attitudes in screening programmes. Participants are informed about the study, after their agreement the questionnaire applied. Data was evaluated using the SPSS for Windows. All tests were two-sided and differences were considered significant when p is <0.05.

RESULTS

The study have shown that nurses who knew well about symptoms, risk factors and screening methods of cancer were more likely to use breast and cervical cancer screening methods.

CONCLUSIONS

In fact, nurses do not have a primary role in the education about the cancer risks and prevention as well as screening methods; however, they have been chosen for this study for two reasons; they were expected to have higher knowledge about cancer due to highly scientific working conditions than counterparts working outside the university hospital and the second reason was the fact that women in our country feel nurses more closely to ask something about the sex specific cancers such as breast and gynecological cancers. Thus, they can constitute a model of health promotion for women.

P-0690**Factors affecting people's capacity for self-control in smoking cessation**

Esra Zengin¹, Adem Bahadır², İsmail Kasım³, İrfan Şencan³, Rabia Kahveci³, Adem Özkara⁴

¹Department of Family Physician, Dr. Fahrettin Uğur Refahiye State Hospital, Erzincan, Turkey

²Department of Family Physician, Rize Kalkandere State Hospital, Rize, Turkey

³Department of Family Physician, Ankara Numune Research and Teaching Hospital, Ankara, Turkey

⁴Department of Family Physician, Hitit University Çorum Faculty of Medicine, Çorum, Turkey

BACKGROUND & AIM: Smoking leads to the preventable death of 5.4 million people every year. In the group of people who can not quit smoking the ability of coping with problems is worth exploring. The aim of this study is to investigate self-control attitudes of patients and effects on smoking cessation.

METHODS: This study includes 158 patients in three groups who applied to family medicine outpatient clinic in 2015. A questionnaire to investigate sociodemographic characteristics was admitted to the patients with a self-control questionnaire. Three groups consists of non-smokers, smoking quitters and non quitters.

RESULTS: 102 of 158 included patients were smokers. 54.9% of smokers had physical ailment. The rates of smoking cessation was 50%. Older age, male sex, having 3 or more children, education and physical ailment were determined to be associated with quitting smoking. In the patients who quit smoking points that belong to self-control and components were higher compared to patients who did not quit. According to the regression analysis results; in Model-I while self-control (OR=1,102, p=0,001), being male (OR=9,763, p=0,014), having university graduate (OR=0,188, p=0,035) and having physical ailment (OR=33,756, p=0,001) are effective factors in quitting smoking, according to the Model-II experiential self-control (OR=1,205, p=0,001), regenerative self-control (OR=1,163, p=0,001), being male (OR=25,482, p=0,002), having university graduate (OR=0,056, p=0,001) and having physical ailment (OR=53,629, p=0,001) were determined as effective factors in quitting smoking.

CONCLUSION: Family physicians have an invaluable role in helping a smokeless society. Interventions to increase self-control among members of the society seem to be effective in reducing smoking rates.

General Health Conditions and Smoking Habits of Firefighters in Ankara

Gizem Bilgin, Tijen Sengezer, Adem Ozkara, Gamze Bal Erbas

Department of Family Medicine, Ankara Numune Training and Research Hospital, Ankara, Turkey

OBJECTIVE

In this study, the aims are stating the medical conditions of firefighters a risky occupational group, investigating smoking behaviors and advice to policy makers for making their health conditions better.

METHOD

This is an observational and descriptor research. All of 881 firefighter who apply ANEAH Sıhhiye Family Medicine Polyclinic for routine medical screening are involved in the study. Medical records of the fire officers are taken by the face to face and detailed examination forms including occupational and smoking histories, chronic illnesses are filled in.

RESULTS

98.3% of firefighters were male (n=774), 1.7% were female (n=13) from the 787 firefighters who are participated in the study. The average age 43.6, average height is 173.4 cm, average BMI has been found 27.3. The average working time in fire department is 16.7 years. 33.9% of firefighters (n=267) have disease that diagnosed previous. 31,5 % of firefighters (N=248) have had an operation. 17,9 % of firefighters (N=141) have had an occupational accident, had been injured. Smoking rates in firefighters is 48'4% (n=381). The rate of quit smoking is 24,3 % (N=24,3). The rate of thinking about quit smoking is 63,2% (N=239). 75,3% of smokers (N=283) has tried to quit smoking before. 27,4% of firefighters (N=216) do exercise regularly.

CONCLUSION

An action plan to improve the health of firefighters should be established.

Family physicians should take preventive measures to improve firefighter health and should monitor firefighter with chronic diseases. Firefighters should be encouraged to contact their family physician.

Firefighters with the highest smoking rates(%48) compared with the average of Turkey (TÜİK 2012, 28%; %41 man, %18 women) should be encouraged to quit smoking.

The food quality at workplace and diet of firefighters which have the rate of obesity as 21% have to be increased. Firefighters should be encouraged to make exercises and sports activity.

Inflammation and Novel Atherogenic Markers in Nondiabetic Obese Patients: Neutrophil to Lymphocyte Ratio, Atherogenic Index of Plasma

Ozlem Cigerli¹, Asli Dogruk Unal², Hulya Parildar¹, Nilay Ergen³, Ozlem Tarcin², Betul Ugur Altun², Nilgun Guvener Demirag²

¹Department of Family Medicine, Baskent University, Istanbul, Turkey

²Department of Endocrinology, Baskent University, Istanbul, Turkey

³Department of Physiology, Baskent University, Istanbul, Turkey

Background & AIM: Inflammation plays a key role in obesity and atherosclerosis. We aim to assess the relations between Framingham risk score (FRS) and Hs-CRP, ferritin, neutrophil to lymphocyte ratio (NLR), Atherogenic Index of Plasma (AIP) for evaluation of inflammation and subclinic atherosclerosis in nondiabetic obese patients with no history of coronary heart disease or stroke.

METHOD: In this study included 185 nondiabetic obese patients and 90 age-sex matched normal weight healthy controls. Blood cell count, differential leukocyte count, Hs-CRP, ferritin, lipids and other parameters were measured. Logarithmic ratio of triglycerides to HDL was defined as AIP. ROC curves conducted to evaluate the performance of the inflammation variables in detecting FRS \geq 10% for study population at moderate to high cardiovascular disease risk.

RESULTS: The mean age of the obese patients was 37.8 \pm 10.7 years (range 17-55) and female patients were 64.3 % (n=119). Mean BMI was in obese patients 35.6 \pm 5.6 and 22.9 \pm 2.2 in controls (p<0.001). Mean serum, ferritin, Hs-CRP levels, neutrophil and platelet count, NLR, AIP and Framingham risk scores of obese patients were significantly higher than controls. Framingham risk scores, AIP, ferritin were significantly higher in obese male patients than obese female patients. Positive correlations were found between BMI and platelet, neutrophil, and lymphocyte Hs-CRP, ferritin, Framingham risk score, NLR, AIP, levels. The ROC analysis demonstrated AIP which has an area under the curve of 0.841, has a high performance in detecting cardiovascular risk according to the Framingham scale (\geq 10%).

CONCLUSIONS: Novel biomarkers as NLR, AIP appear to be related with Hs-CRP levels and useful as inflammatory markers for evaluation in clinical setting. These markers are also inexpensive, cost-effective, simple applicable, and universally available tests. Framingham risk score is significantly higher and also AIP may contribute as a considerable marker for prediction of subclinic cardiovascular risk in nondiabetic obese patients.

Behavior of Health Workers in Treating Pulmonary Tuberculosis in Manado Community Health Center, North Sulawesi, Indonesia

Henry Palandeng¹, Joy Zeekeon², Dina Rombot¹, Natasha Pongoh³

¹Department of Community Medicine, Faculty of Medicine, Sam Ratulangi University

²Health Department, Manado City

³Medical Student at Faculty of Medicine, Sam Ratulangi University

Tuberculosis is an infectious disease caused by the bacteria *Mycobacterium tuberculosis*, which has become a global threat. There is Tuberculosis control efforts that have been made to reduce the incidence and prevalence of this disease. The success of Tuberculosis treatment cannot be separated from the role of health professionals in this case health workers, which have a direct contact with patients with Tuberculosis. This study aims to determine the behavior of particular knowledge, attitude, and practice of health workers in community health centers, in Manado City. This is a descriptive study. Sampling in this study are 75 health workers. The data was collected through questionnaires. The result showed that majority of respondents are 26-35 years, were 39 respondents (52,0%); most of them are female with 65 respondents (86,7%) and it shows that the career development stages of this age group are included in the third phase is the implementation which the individual began to apply their knowledge to work according to their expertise. In this study, we found that the respondents have good knowledge, attitude and practice for treating patients with tuberculosis. Hence, the health workers are expected more frequently providing information so that the public can better prevent the spread of this Tuberculosis disease.

Care Burden of Caregivers of Home Health Care patients and Related Factors

Pemra C. Ünalın, Nazire Öncül Börekci, Seda A. Özkul, Çiğdem Apaydın Kaya
department of family medicine, marmara university, Istanbul, Turkey

OBJECTIVE:

Caregiver is the person who is helping the patient to deal with the illness and this help includes physical, emotional and tangible support. This intensive working effects the caregivers of the patients who are confined to house or bedridden. This study explores the patients' and caregivers' characteristics, burden of care and potential factors effecting this.

METHOD:

Caregivers of the registered patients of our home health care unit, aged 65 years or older, with Serebrovascular Disease were included. 69 caregivers were assessed using Zarit Caregiver Burden Inventory, sociodemographic information form, general self-efficacy scale, Inventory of socially Supportive Behaviors. All scales were 5-point Likert scale. Zarit Caregiver Burden Inventory consists of 22 items with total points of 88. 3 items selected from Inventory of socially Supportive Behaviors with total points of 12 and 5 items from General Self-efficacy Scale with total points of 25 were used for assessment. Chi-square and Student-T tests were used in the data analysis, $p < 0,05$ was significant.

RESULTS:

Caregivers were at the mean age of 48,22 ($\pm 10,6$) with the mean duration of caregiving of 4,61 ($\pm 3,64$) years. Of the 69 caregivers, 85,5 % (n=59) were female, 63,8 % (n=44) had low education level (≤ 5 years), 79,7% were giving care continuous. Social Support Point, Self-efficacy Point and Zarit Caregiver Burden Inventory mean scores were 3,5 ($\pm 2,44$), 19,8 ($\pm 4,43$) and 54,9 ($\pm 11,24$) respectively. Self-efficacy scores were higher at male gender, intermittent caregivers and higher education level (> 5 years) ($p=0,033$ $p=0,006$ $p=0,006$ respectively). These groups had no statistically significant association with Social Support and Caregiver Burden

CONCLUSION:

In this study Burden of care was assessed at severe levels and Social support was poor among our patients. By comprehensive studies, exposure of the factors contributing to burden in caregivers would be beneficial for both the patient and the caregiver.

Keywords: caregiver burden, home health care, social support, self-efficacy

Staying as 'healthy' physicians within the computer-based workplaces Improving the quality of life

Hulya Parıldar¹, Ozlem Cigerli¹, Aydan Aksoyek², Taner Canatar³, Bahadır Yazicioglu⁴, Altug Kut⁵

¹Department of Family medicine, Baskent University, Istanbul, Turkey

²Department of Family medicine, Baskent University, Adana, Turkey

³Family Medicine Specialist, Adana, Turkey

⁴Department of Family medicine, Ondokuz Mayıs University, Samsun, Turkey

⁵Department of Family medicine, Baskent University, Ankara, Turkey

Background and AIM:

Computer-based working and prolonged sitting hours are common among physicians, probably making them at increased risk for musculoskeletal disorders. We aimed to determine the frequency of musculoskeletal complaints (MSC) among physicians.

METHODS:

The present study was a cross-sectional analysis done among 100 physicians working in the outpatient polyclinics in the hospitals, in 2015. This cross-sectional study was performed in physicians working in outpatient polyclinics. They were asked to complete the extended Nordic Musculoskeletal Questionnaire and Visual Analog Scale (VAS) for pain assessment. Student T test ve Pearson Correlation tests were used for comparative statistical analysis.

RESULTS:

Mean age of study subjects was 34.8 ± 7.9 (min=25, max=58), mean BMI was 24.1 ± 3.6 (min=18.2, max=35.8) and 71% were female. Regular physical activity was reported in %21,9. 96% of them did not have any ergonomic training. Regarding hours at work spent in front of a computer, 60 (20%) reported spending >8h/day, (22%) spent 0-2 h/day.

73% of the physicians reported having MSC in one or more regions in the last 12 months; pain/stiffness in the neck and back were the most frequently reported complaints; 43.8% and 24.6%, respectively. Among the physicians who had MSC, 24.7% reported workloss or disability and 58.9% prevention of after-work activities. Mean VAS values over 5 was 49.3%. There was significant increase in complaints among the physicians who spent >4 h/day working on computers ($\chi^2:3.729$, $p=0.045$).

CONCLUSIONS:

The prevalence of MSC and work disability due to these complaints are high among physicians. The prevalence of MSC may be affected by work setting, practice specialty and regular physical activity during work. The physicians themselves need to be aware of the importance of ergonomic training and working conditions. Occupational health of the people working in the computer field with prolonged sitting hours concerns the public health.

Keywords: quality of life, musculoskeletal complaints, ergonomy

Factors influencing utilization of hearing protection devices in high-noise workplace environment

Uzuner Ayşe¹, Hoşcan Ahmet Yahya¹, Avcı Kübra Ceren¹, Gültekin Ibrahim¹, Çukadaroğlu Çağrı², Kaya Gülin¹, Gürün Hande¹, Save Dilşad¹

¹Marmara University, School of Medicine, Department of Public Health

²Turkish Ministry of Health

Background & AIM:

Noise is a serious environmental pollutant because of rising urbanization and industrialization in today's world. Related with this noise-induced hearing loss one of the most important public health problems. Although hearing protection devices (HPD) were available and advised to use for prevention from hazardous health effects of noise it still remain as a neglected area in many workplaces.

This study aims to find out HPD utilization rates and influencing factors which may help to definition of accurate strategies for promoting risk recognition.

Method

The study was carried out in five different bus garages in Istanbul. A questionnaire was applied face to face for each individuals who accepted to participate the study (n=222). The noise level measurements for different working environments were evaluated. Chi-square, t-test and Mann-Whitney U-test applied for statistical comparisons.

RESULTS:

The percentage of the participants who declared to use HPD was found to be 38,7%. Among those who knew that the noise exposure may cause to hearing loss HPD use was not different from those who did not know. The only difference was found for those who perceive the environment noisy to have higher utilization rates of HPD comparing with those who did not. The common reason for not to use of protective equipment was lack of the knowledge of the necessity of continuously HPD during working hours (25%, n=54).

CONCLUSION:

The results of the study indicate that medical doctors in workplaces must play an important role in promoting the regular and efficient use of HPD. The educational and motivational efforts should also concentrate on changing the workers' ability to understand health risks.

Diagnosis and Prevention of Nephropathy Progression in Type 2 Diabetic Patients

Monica Vanessa Mota¹, Tiago Barra², Sara Silva¹, Ricardo Santos¹, José Carvalho¹, Rui Correia¹, Inês Melo E Sousa¹, Frederico Salgado¹, António Filipe¹

¹Unidade de Saúde Familiar Alpendorada, Agrupamento de Centros de Saúde Tâmega I, Marco de Canaveses, Portugal

²Unidade de Nefrologia e Diálise, Centro Hospitalar Tondela-Viseu, Viseu, Portugal

INTRODUCTION: Nephropathy is an important cause of morbidity and mortality in diabetic patients and could be subject of early diagnosis and intervention in order to prevent progression to end stage renal disease. The healthcare team can implement effective strategies in this area, namely: control modifiable risk factors such as hypertension and hyperglycemia; early diagnosis through annual albuminuria dosing and estimation of glomerular filtration rate; and implementation of measures that can delay progression for established nephropathy stage. This study aims to analyze the situation of Family Health Unit (FHU) Alpendorada regarding diagnosis and prevention of nephropathy in type 2 diabetic patients.

METHODS: We conducted a descriptive retrospective study, targeting type 2 diabetics followed-up at FHU Alpendorada in 2014. Data were collected through clinical software SClínico[®], PDS[®], PEM[®] and MIM@UF[®]. Statistical analysis was made through IBM SPSS Statistics[®] using techniques of descriptive and inferential statistics.

RESULTS: We highlight that almost 90% of individuals had undergone nephropathy screening. Of these, 24.1% had incipient nephropathy and 5.2% established nephropathy. On what concerns to preventive measures, almost 100% of patients had a register of hemoglobin A1c, 74.2% of which below 7.0%. All patients had blood pressure registration, 50.7% lower than 140/90mmHg. In patients with indication to perform angiotensin II receptor antagonists or angiotensin-converting-enzyme inhibitors, 82.6% were prescribed with these drugs. Approximately 92% of patients were tested for LDL-cholesterol, 54.8% had values ≥ 100 mg and of these, 50.8% were receiving statin. In patients with albuminuria, cardiovascular risk increased with the progression to established nephropathy stage. The main reasons for referral to nephrology consultation were GFR < 60 ml/min/1.73m² and albuminuria ≥ 300 mg/24h, each of these involving 30.0% of the patients with established nephropathy.

CONCLUSIONS: In FHU Alpendorada, early diagnosis and measures for nephropathy prevention and delaying in type 2 diabetics are in general implemented in accordance with latest guidelines.

Vitamin C and Influenza infections

Ana Marta Garcia, Luís Miguel Paixão
UCSP Fernão de Magalhães, Coimbra, Portugal

Background & AIM: About common cold, a 2013 Cochrane systematic review concluded that Vitamin C supplementation may be useful to prevent it in people exposed to periods of severe physical exercise, but fails to reduce it in general population, and refers that Vitamin C has shown consistent effect on decreasing duration and severity of colds. Would the results be similar when referring specifically to influenza infections? The aim of this review was to evaluate the effect of Vitamin C in the prevention and treatment of influenza infections.

METHOD: Evidence based databases including Pubmed articles combining the MESH key words "Vitamin C" and "Influenza" were searched.

RESULTS: 169 articles were found; 8 corresponded to the review aim: 3 systematic reviews, 1 prospective controlled study, 1 RCT, 3 in vitro studies. In vitro studies show that ascorbic acid can boost immune response and inhibited proliferation of influenza virus in cell cultures. One RCT included in a review demonstrates lower

incidence of pneumonia and hospitalization permanence in patients with influenza infections that received vitamin C 300 mg/day. A prospective controlled study reported significant decreased of reported flu and cold symptoms in the group taking 1000 mg of Vitamin C. One RCT hasn't showed any effect of a multivitamin compound containing ascorbic acid in influenza infection prevention in elderly. The hypothesis that combined inhalation/oral supplementation of ascorbic acid may prevent influenza infection was raised in a review. CONCLUSIONS: Most of the existent evidence about vitamin C use in influenza infections is based on in vitro studies. The little and poor evidence found about its preventive or therapeutic role is in keeping with the consistent one founded to common cold, namely, probably no effect on prevention and maybe an effect in decreasing duration and severity of symptoms. Nevertheless, further therapeutic RCTs are warranted.

Does educational status affect the frequency of home accidents? A descriptive study from Istanbul, Turkey

Nurdan Yiğit¹, Tefik Bayram¹, Gizem Erdem¹, Emre Kocazeybek¹, Fatma Zehra Avşar¹, İsmail Dikmen¹, Oğuz Kaan Şimşek¹, Yasemin Çomak¹, Hayriye Kubilay Yüksel², Dilşad Save¹

¹Marmara University, School of Medicine, Department of Public Health

²Turkish Ministry of Health

BACKGROUND AND AIM

Home accidents has high prevalence and cause serious mortality and morbidity among infants and children. The main questions of the study are if current knowledge and practice of preventive measures sufficient to decrease the prevalence and if higher educational status of women may help to decrease the prevalence.

Thus aim of the study is to evaluate knowledge, attitude and practice of mothers who has 0-5 years old children and the factors affecting them.

METHOD

This study is a descriptive study and carried out in two Family Health Centers in Istanbul, Turkey. The questionnaires were administered by face to face interviews to the mothers who admitted to these centers and have 0-5 years old children (n=204). Chi square and t_-test were used in statistical comparisons; p<0,05 is considered as significant.

RESULTS

Type of home accidents were identified as fall(70,5%), shock(50,5%), burn(17,4%), drowning(7,9%), cutting and penetrating traumas(10,6%), poisoning(9,0%). Having any type of accident was 92,6%. The most common cause of poisoning was cleaning products(bleach: 27,3%; soap: 13,6%; shampoo: 13,6%; dish soap: 4,5%). The most common precaution taken was keeping cigarette, match, lighter away of children(80,3%). It is significantly seen that mothers who has university/upper level educational status(p <0,001) and have taken first aid courses take more precautions(p <0,001). However, there was no significant difference between educational status and frequency of accidents.

CONCLUSION

Taking the results of this study into consideration, awareness and knowledge about the preventive measures need to be improved in community. The current education program was not found to be sufficient to prevent home accidents. Specific courses aiming parent population could be more beneficial.

Keywords: home accidents, knowledge attitude and practice, fall, educational status, health education, preventive medicine.

Evaluation of knowledge and attitudes about adult vaccines, and the vaccination rate in adults over the age of 18, the first findings

Melahat Akdeniz, Bekir Ineli

Department of Family Medicine, Akdeniz University, Antalya, Turkey

Background: Immunization against vaccine preventable diseases is one of the most important and beneficial public health measures available. Vaccine-preventable disease (VPD) continues to take a heavy toll on adults despite the widespread availability of effective vaccines such as influenza, pneumococcal infections, herpes zoster, human papillomavirus, hepatitis B, and tetanus, diphtheria, and pertussis. However, utilization rates among adults remain low, well below World Health Organization' target levels. Studies on adult vaccination rates are very low and the data are limited in Turkey. In this study, It is evaluated of vaccination status of adults, the knowledge about vaccines and attitudes related immunization attitudes.

Materials and Methods; This study is done by a questionnaire application that we developed on patients presenting for any reason in Family Medicine Clinic. The questionnaire was filled with face to face interviews.

FINDINGS: The number of people participating in the study are 210 Until 1 June 2015. Percent 22 of study participants are health workers. The proportion of patients with chronic disease is 34%. The proportion of people stating that the information on adult vaccines is 41.9%. The proportion of people stating that informed about the vaccine by health care workers is 10.7%. The most known vaccine is influenza vaccine (69%); and the least known vaccine is haemophilus influenzae type b vaccine (12.6%). Those taking no vaccination rate was 66.5%. The most received vaccine is tetanus vaccine (46%). The most frequently reported reasons for not getting vaccine are the lack of information about the vaccines. 66.5% of respondents are demand to inform themselves by their family practice.

CONCLUSION: The knowledge about Adult Immunization is insufficient in the community. utilization rates among adults are very low. Participants are expected to inform the vaccines they need to make by their family physician.

Knowledge, attitudes and practices concerning Middle East respiratory syndrome among Umrah and Hajj pilgrims in Samsun, Turkey, 2015

Mustafa Kürşat Şahin¹, Servet Aker¹, Ebru Kaynar Tuncel²

¹Canik Community Health Center, Samsun, Turkey

²Bafra Community Health Center, Samsun, Turkey

Background & AIM: The number of pilgrims attending the annual Hajj or Umrah each year is about 10 million, and these pilgrims originate from 184 countries. After its emergence in June 2012, most cases of MERS-CoV infections were reported from Saudi Arabia. The aim of this study is evaluated Umrah or Hajj pilgrims' knowledge, attitudes, and practices about MERS-CoV. METHOD: We conducted a KAP survey that addressed MERS and its prevention among Umrah or Hajj pilgrims during six weeks, from 4 May to 12 June 2015. Data were collected by the researcher, applying face-to face structured interview techniques with a questionnaire developed after a relevant literature review. Data were analyzed using SPSS 22.0 package program. In the analysis, frequency and percentage from descriptive criteria were used. RESULTS: A total of 259 pilgrims participated. They were between 17 and 85 years old (median: 59 years), and 47.5% (123/259) were male. Nearly half (119/259) had a primary school degree. Some of the participants had pre-existing chronic medical conditions.(Table 1) Seventy-eight per cent (203/259) of respondents performed Hajj or Umrah for the first time. Nearly half of them(131/259) had heard MERS from TV or health professional. When informed about the potential effectiveness of prevention measures against respiratory infection (use of face masks and disposable tissue, hand hygiene, social distancing and avoiding touching eyes, nose and mouth) most pilgrims were willing to apply such measures. CONCLUSIONS: Although the results cannot be extrapolated to all Hajj pilgrims, they show that pilgrim's departing from Turkey were aware of the ongoing MERS epidemic

Allergic contact dermatitis caused by a cell phone cover

Gülben Sarıcı¹, Yasemin Korkut²

¹Department of Dermatology, Dumlupınar University, Kütahya, Turkey

²Department of Family Medicine, Dumlupınar University, Kütahya, Turkey

AIM:

Allergic contact dermatitis(ACD),is also called dermatitis venenata.ACD results when an allergen comes into contact with previously sensitized skin.ACD results from a specific acquired hypersensitivity of the delayed type, also known as cell-mediated hypersensitivity or immunity. The most common causes of contact dermatitis are the following:toxicodendron,nickel, formaldehyde, bacitracin and rubber compounds.

CASE:

Symmetrical,sharply demarcated erythematous,squamous plaques on the cheeks were observed in the physical examination of 32-year-old female patient admitted to polyclinic with complaints of pruritic eruption in the facial region.When questioned that contacting allergens by considering contact dermatitis,it was learned that the patient has talked with a mobile phone about 3 hours per day.

Pruritic eruptions have occurred on the abdominal region in patients 1 year ago,the patient's complaint was considered to be due to belt buckle,patch test was performed,it was determined that the patient has nickel allergy.

It was considered that the patient's symptoms were depending on the mobile phone,therefore it was said to the patient that she should give up contact with mobile phone or the metal parts of mobile phone should be coated with nail polish.Symptoms were resolved completely 15 days after starting topical steroids.

CONCLUSION:

Nickel ranks as the most common allergen tested by the NACDG(North American Contact Dermatitis Group),with 16.7% of patch test clinic patients reacting to it.In patch test clinics worldwide, nickel is the most common allergen.The relevance of these reactions has been estimated to be 50%, suggesting that although this is a common allergen it is not always relevant to the dermatitis in question. Some clinicians advocate coating nickel-containing surfaces such as snaps on jeans with clear nail polish to prevent leaching by sweat onto the skin. However the nail polish can rub off and should be reapplied if it is effective.

Measurement of knowledge about Sexual Health in Kutahya

Yasemin Korkut, Işıl Atmaca

Department of Family Medicine, Dumlupınar University, Kütahya, Turkey

AIM:The purpose of this research is to determine the knowledge and beliefs about sexual health of people living in Kütahya.

METHODS:

The sample of the survey conducted in Kütahya who agreed to participate in the research consisted of 105 people between 17-80 years of age. This study is cross-sectional and descriptive type. Data were collected using a questionnaire. Evaluation of the data; definitive tests were used.

RESULTS:

The average age was 33.80. Only 6.7% of the participants' family and can talk freely around this issue and information from friends about sexuality 45.7%, 22.9% that they had received from the partner.

8.5% of the women in the study, 2.5% of men had received information about sexual and reproductive health of men and 73.4% of 80.6's% of women reported that they had received this information from the mass media.

Secure the opinions of the participants asked said they heard about the sexual intercourse for the first time 9.4%, said the need to use protection methods 44.7%. The participants in the prevention of sexually transmitted diseases were seen to have a clear picture of 63%

CONCLUSION:

In the faculty of medicine of the participants where the students sexual health-related personal hygiene and sexually transmitted is determined to have false beliefs about infection, family medicine clinic in the medical or allied health workers by sexual and reproductive health related information and misinformation on the subject of providing consultancy services and a little bit will be more effective in preventing beliefs.

"{" Evaluation Of Complete Blood Count Profile Of Who Refer For Occupational Health Examination }"

Gülseren Oktay¹, Yunus Emre Kuyucu², Nagihan Yıldız Çeltek¹, Ramazan Tetikçok¹, Ufuk Ünlü¹

¹Department of Family Medicine, Gaziosmanpaşa University Faculty of Medicine, Tokat, Turkey

²Department of Biostatistics, Gaziosmanpaşa University Faculty of Medicine, Tokat, Turkey.

"" **AIM:** The purposes of occupational health service are keeping employees healthy and resuming this, protecting employees from potential harmful effect of working conditions, and to employ people according to their physiologic and psychologic health. During reference many diseases may be detected in the early period via required examinations. We aimed to evaluate, retrospectively, complete blood count (CBC) values.

METHODS: Patients, whom diagnoses are occupational health examination, who refer to Gaziosmanpaşa University of Family Medicine policlinic between the date of 01.01.2014-01.03.2015 were accepted to this study. CBC values were evaluated retrospectively. Patients who were not studied CBC were excluded from the study. Hemoglobin, hematocrit, Platelet, Red Blood Cell, White Blood Cell values are saved.

RESULTS: 124 patients are diagnosed as occupational health examination by Gaziosmanpaşa University of Family Medicine policlinic between the date of 01.01.14- 01.03.15, however 76 patients were studied CBC. Most of the patients (63,2%) were males. The average age of the patients was $31,57 \pm 7,56$ and the average hemoglobin value was $15,4 \pm 1,99$ mg/dl. 7,1 % of women were anemic, while there was not anemic patient among men. 19 male patients' (39,6%) hemoglobin values were over 17 mg/dl and 2 female patients' hemoglobin values were over 15 mg/dl.

CONCLUSIONS: Common diseases among society are encountered among employees population frequently. So anemia is still one of the most important public health problems of the improving countries. This study 2,6 % patients were anemic. In this study it is seen that 27,6% of the patients should be examined as polycythemia and to examine reasons of relative erythrocytosis. Finally, many diseases can be diagnosed in asymptomatic period during occupational health examinations. Therefore, to allowing enough time for patients is important, but this is only be

provided by reducing the intensity of the patient and workload "".

Does our elderly vaccinated?

Sıdıka Büşra Korkmaz, Mavişe Esra Ünüvar, Güzel Dişçigil
Department of Family Medicine, Adnan Menderes University, Aydın, Turkey

Nowadays, an increasing number of aged people are living a healthy and still vigorous and independent life. For a healthy and functional late-life, preventive health services are becoming important.. One of the most important of these preventive approach is vaccination.

After receiving the necessary permits for our work as a cross-sectional analytical study, we applied a questionnaire what the applicant 60 years of age and immunization were reached by phone calls person on the circumstances at Adnan Menderes University between January 2010 and May 2014 Family Medicine Outpatient Clinic, In this study, The data of 400 elderly individuals whom admitted to our clinic were analyzed. We evaluated the data we obtained statistically.

279 female patients (69.8%) and 121 men (30.3%). Those in the 60-69 age range from 201 patients (50.3%), those in the 70-79 age range 135 (33.8%), those over 80 and 64 (16%) were men. Those who perform the influenza vaccine 4 (1%), those who make the pneumococcal vaccine 4 (1%), those who get tetanus vaccine 5 (1.3%) were men. When asked me why people who are not vaccinated with the vaccine; those who make the flu vaccine 241 (60.3%) did not know, 153 (38.3%) not be in need of., 2 (0.5%) in the form of replying forgot; those taking 241 of pneumococcal vaccine (60.3%) did not know, 152 (38%) di not be in need of. 234 of those taking tetanus vaccination (58.5%) did not know, 159 (39.8%) not be in need of.

The majority of elderly individuals in the study were not taking the vaccine. This result showed that ther is not enough awareness of elderly about vaccination, family medicine practice to emphasize the importance of vaccination in the elderly and illustrates the need to be informed about it

Fatigue and Sleeping Quality in Medical Students

Kübra Uyar, Rana Gündoğan, Özge Berfu Gürbüz, Nilgün Özçakar
Dokuz Eylul University Faculty of Medicine, Family Medicine Department, Izmir

Background&AIM: Sleep is one of the physiological steps of physically and mentally healthy living. Sleep quality is related with feeling fit and being ready for a new day after waking up. The people who have poor sleep quality are forced for issues requiring further attention and concentration during day period. One of the most important factors affecting quality of sleep is fatigue. Tired people have difficulty in sleep transition period and restful sleep process. Medical students are among the groups that having intensive stress, fatigue and sleep problems. Stress, strain and hard theoretical/practical training of medical education makes a reduction in time spent asleep and also sleep quality.

METHODS: In our cross sectional study we applied to 4,5 and 6th grade medical students a questionnaire including socio-demographic characteristics, Pittsburg Sleep Quality Index (PSQI) and Piper Fatigue Self-Report Scale (PFSS). Chi-square and t tests were used for statistical analysis, $p<0.05$ was considered significant.

RESULTS: Participant's (n=290) mean age was 23.47 ± 1.33 and 53.8% were male. It's found that alcohol use 40.3% (n=117), nutritional drug use 40.7% (n=118) and smoking 19% (n=55). Participants who prefer to sleep in dark were 86.2% (n=250). They think that drinks they used before going to bed partially affect their sleep quality (37.9%). PSQI average was 10.56 ± 2.54 (min:5-max:19). The 98.6% of participants have poor sleep quality. PFSS mean score was 2.85 ± 0.83 (min:1-max:5) and 79% of them (n=229) had mild stage fatigue. The PSQI and PFS scores was related statistically significant ($p<0.05$).

CONCLUSION: We found a significant relationship between the levels of fatigue and sleep quality. Although large proportion of participants has bad sleep quality, the level of fatigue was mild. Arrangements should be made to correct the poor sleep quality which affects the quality of life and fatigue levels contributing to the high rate sleep quality might be reduced.

Demonstration of the Fact of Active Aging with Fully-Protected Cognitive Processes of an Old Person Living in Residential Home

Gül Kayserili¹, Nil Tekin²

¹Narlidere Residential and Nursing Home, Neuropsychology, Izmir

²Narlidere Residential and Nursing Home, Family Medicine, Izmir

OBJECTIVE: Maintaining the health in the advanced age and active aging is becoming more and more significant as the elderly population increases in the world and our country. It was shown in our study with a case that in spite of advanced elderly phase and risk factors, maintained cognitive functions functioning like a healthy adult can be possible by means of the effort of active aging.

METHOD: In this study, data of woman, 88-year old, university graduate living in residential home are presented. Data about cognitive functions by clinic interview and observation were obtained with Mini Mental Status Evaluation (MMSE), 5 words test (5WT), Wechsler memory scale number range sub-test (WMS-SMT), clock drawing test (CDT).

FINDINGS: It was learnt that the person walked regularly and traveled frequently and read books with daily newspaper regularly. It was noted that she sustained her social life by including new persons in the relations with family and friends and cared about healthy eating. Moreover, she developed individual coping skills for protecting herself mentally in spite of trauma history she lost her child and also long recent operation process. As a result of neuropsychological tests conducted, MMSE score was 30 above 30, 5WT score was 10 above 10, CDT score was 4 above 4 and WMS-SMT score was 6 above 7.

CONCLUSION: Healthy diet, physical activity, being efficient in daily life, sustaining social relations by renewing and developing individual psychological suggestion techniques were observed in the case. Moreover, she

continues cognitive activities regularly such as reading and traveling making a number of parts of brain function simultaneously. Consequently, based on total scores achieved in cognitive rating scales, the significance of active aging, the fact that cognitive functions can be maintained in spite of a number of advanced age risk factors were revealed in this case.

Keywords: Old age, Active aging, cognitive functions

Evaluation the Results of a Health Scan Conducted in a Rural District of Konya

Kamile Marakoğlu, Muhammed Kızmaz, Nisa Çetin Kargın, Seda Sazak, Ali Altınok, Emre Ay, Ahmet Ayrancı, Asiye Betül Cebeci, Ramazan Duran, Abdurrahman Altun

Department of Family Medicine, Selcuk University Medical Faculty, Konya, Turkey

AIM: To reach the patients who cannot find the opportunity to reach a hospital or a doctor due to financial or other reasons, and to provide health care to the place where they live are among the tasks of Family Physicians. For this purpose, this study aimed to evaluate the results of a health scanning conducted in a rural district of Konya.

MATERIAL-METHOD: On April 20, 2015 health screening was performed in Taşkent, a town in Konya, by Faculty of Medicine of Selcuk University. Examinations were performed in a fixed area, and a short questionnaire was administered through face-to-face interviews with 112 patients. Prescriptions were written to patients who required treatment as a result of medical history and physical examination.

RESULTS: Of the 112 patients who participated in our screening 67.9% were female and 32.1% were male. The mean age of the patients was 57.33 ± 14.76 , 89.3% were married, 3.6% single and 7.1% were divorced. 24.1% of patients were at normal weight, 33.9% were overweight and 41.1% were obese. 46.42% of the complaints of the patients were pain. 55.7% of the patients with pain were complaining of musculoskeletal pain. Blood glucose starvation of 106 people and the postprandial blood glucose of 6 people was measured with a glucometer device. 41.1% of the patients were considered normal, 25.9% DM and 33% were considered prediabetes according to of measured blood glucose. According to the history and measured blood pressure of the patients, 33% had a diagnosis of hypertension.

CONCLUSION: DM, HT and obesity that have become important public health problems in all over the world and our country have been found to be prevalent in this district. It is essential that family physicians diagnose chronic diseases with simple examination and tests in the first step, train the patients, not delay treatment and refer them to specialist.

An effective educational model for the empowerment of exclusive breastfeeding

Naciye Irmak, Arzu Uzuner, Burcu Başaran, Sevim Aksoy, Esmâ Özçelik
Marmara University Family medicine department

Introduction and BACKGROUND: Breastfeeding education by group during the prenatal period provides significant increase in the frequency of exclusive breastfeeding for the first six months according to the individual breastfeeding education. In this paper a “person-centered training module for the empowerment of personal development” structured according to the principles of adult education is presented.

METHOD: The training was realized by the participation of a group of 6 to 8 pregnant women in the second and third trimester of their pregnancy. A first session of 45 mn was followed by a break of 10 mn and a second session of one hour. All the participants were motivated to actively participate in the training. And also by highlighting the experienced mothers’ beneficial sharings were also supported as a group interaction. The themes related to the barriers against exclusive breastfeeding and to how to overcome these obstacles, were used in the role-play section, video and slide presentation. It was aimed to attract mothers’ attention by using cultural and traditional motifs in the role-play. And also the breastfeeding position was shown to every pregnant woman one by one on model babies and they were requested to practice by themselves and an appropriate improving feedback were

given. At the end of the training, the mothers' questions were answered without time limitation. The training ended by taking the mothers' written feedbacks about the education and by the distribution of brochures and small gifts for baby care.

Discussion-CONCLUSION: The advantages of this education program were: being designed by experienced people by considering the principles of adult education, being a cost effective packet programme with standardized content applicable in primary care. The limitation is the requirement for a suitable physical environment for group training. The effectiveness of this programme can be evaluated by applying it to many pregnant women and by observing them via scientific methods.

Evaluation of the Relationship Between Fluid Consumption Habits and Metabolic Syndrome

Şükrü Ümit Eren¹, İsmail Arslan², İzzet Fidancı³, Gökçe Dilek Işcan⁵, Salih Dilber⁴, Oğuz Tekin²

¹Kızılırmak County Public Hospital, Çankırı

²Ankara Training and Research Hospital Family Practice Clinic, Ankara

³Atakum Community Health Center, Samsun

⁴Orta County Public Hospital, Çankırı

⁵Gölbaşı Community Health Center, Ankara

PURPOSE: We aimed at comparing the fluid consumption amounts and fluid consumption habits of the patients, who live in Ankara and evaluating the relationship between these features and Metabolic Syndrome (MetS).

MATERIAL-METHOD: 102 from Bahcelievler (urban) and 99 from Huseyingazi (rural) (totally 201) patients attended to our study and asked sociodemographic attributes, fluid consumption habits and 24 hours of fluid consumption amounts and the "International Physical Activity Questionnaire". The data was analyzed via SPSS 16.0

FINDINGS: in our study MetS is seen at the rates of 60.5%, 54% and 57.7% respectively in women, men and in general. The factors that may affect MetS were assessed through logistic regression analysis. "Living in rural areas" was increasing the risk of MetS incidence 1.5 times ($P=0.02$). We saw that MetS prevalence increased with "age" ($P=0.001$) and it was significantly

higher in "women" ($P=0.006$). MetS prevalence was found lesser in those with "high physical activity" ($P=0.001$). Considering the relationship between the consumed fluid type and MetS, we observed that MetS prevalence was lesser in those consuming "calorie-free fluid" ($P<0.001$), with "high water consumption" ($P<0.001$) and with "higher daily total fluid consumption" ($P=0.007$). And we saw that the MetS prevalence had increased in those who "consume calorific fluids" ($P<0.001$). "Keeping water on dining table" ($P=0.003$) and "carrying water during the day" ($P<0.001$) increase the amount of water drunk.

RESULT: The beverages consumed by patients and their amounts of calorie are as important as the calorie they receive with feeding. Fluid intake must be provided sufficiently both in the struggle with obesity and MetS; it is necessary to emphasize that the fluid need should be met by calorie-free beverages. The consumption amount of water, which is a calorie-free and easy accessible beverage, must be increased. "Drink water for a dirt cheap treatment."

Periodic Health Examination And The Case Of Asymptomatic Colorectal Cancer

Meryem Solak Karabörk¹, Yaşar Koşar¹, Ertan Bülbüloğlu², Ayşegül Erdoğan³, Mustafa Çelik¹

¹Department of Family Medicine, Kahramanmaraş Sütçü İmam University, Kahramanmaraş, Turkey

²Department of General Surgery, Kahramanmaraş Sütçü İmam University, Kahramanmaraş, Turkey

³Department of Public Health, Kahramanmaraş Sütçü İmam University, Kahramanmaraş, Turkey

INTRODUCTION: In terms of mortality and morbidity rates, colorectal cancer is one of the most common cancers in the world. With screening tests, precancerous lesions or tumors can be detected earlier thus decrease in morbidity and mortality rates is achieved. In this study detection of an asymptomatic colorectal cancer case during periodic health assessment is discussed.

CASE: 67-year-old male visits his family doctor for periodic health assessment without any complaint. Patient has been followed with essential hypertension diagnose for 20 years. His vital findings are stabile and his examination is insignificant. In laboratory tests; WBC: 5.4 K/UI, Hb: 15.1 g/dl, HTC: 45.9%, MCV: 84.2 fl, Ferritin: 7.8 ng/MI. Fecal occult blood test is positive in two consecutive samples.

Colonoscopy is performed in the gastroenterology department: A 5 mm polyp in the distal transverse colon, a 7 cm polypoid mass in the proximal descending colon and a 17 mm polyp in the distal sigmoid colon are detected.

Polypectomy is performed. Biopsy of specimens are found to be consistent with adenomatous polyps.

Surgery is recommended by general surgeon because of its size (more than 6cm) and malignancy risks. Patient underwent laparoscopic left hemicolectomy, with general anesthesia. Left hemicolectomy material is consistent with tubulovillous adenoma.

DISCUSSION and CONCLUSION: Morbidity and mortality rates of Colorectal Cancer remains as an important public health issue in our country likely to the world rates. Decrease in morbidity and mortality rate and decrease in the health expenses with early diagnose is shown in previous studies. To this end, each country constitutes a screening test program according to their own characteristics. Family doctors keep an important role for early detection of asymptomatic colorectal cancer cases with fast, easy and cost-effective approach.

Medical Students' Knowledge and Vaccination Status In The Last Year Of Their Education

İlyas Erken, Sema Kılıç, Ozan Fırat Kuz, Gizem Limnili, Nilgün Özçakar

Department of Family Medicine, Dokuz Eylül University Medical Faculty, Izmir, Turkey

Background&Aim

Preventive health service can be grouped as for people and environment. Immunization has an important position in preventive health care. Vaccination service evaluated in two groups as childhood and adulthood vaccines. Both in countries and worldwide, immunization of adults isn't at desired level that vaccine-preventable diseases lead to undesirable results. To have current information and right application of adulthood vaccines is a particular importance for physicians. In this regard, different types of vaccines, knowledge about immunization have been studied and found insufficient; a need for more informed work for society health was stated.

Our aim is to determine level of vaccination knowledge and vaccination status of medical students in the last year of their education.

Methods

In this cross-sectional study, a questionnaire applied to Grade 6 students, to determine the vaccination status and knowledge of vaccines

Results

In our study 51.1% of 176 participants is female and mean age is 24.45±1.01 (min=22, max=31).

In evaluation of vaccination status; 88.6% vaccinated for hepatitis B, 7.4% for pneumococcus, 4% for HPV, 74.4% for tetanus, 18.8% for flu. Their reason asked for not being vaccinated; 44.3% had no reasons, 30.1% thought

vaccination is not necessary. There was no significant difference between genders for reasons not being vaccinated ($p > 0.05$). Right answers about vaccine protection level was; 81.9% for hepatitis B, 64.2% for HPV, 49.4% for tetanus. Hepatitis B vaccination schedule responded correctly (92.6%). Rappelling HPV wasn't known (33.5%), while age range of the application correctly answered (52.3%). Participants stated that flu vaccine can be applied to pregnant (64.8%).

Conclusions

Medical students' knowledge about adult vaccination found moderate. More importance should be given on this issue. Medical students should complete their knowledge of adult immunization like other ages; it will provide the improvement of health care quality in terms of preventive health.

P-0713

A Case with Caesarean Section Scar Endometrioma

Ilyas Erken¹, Gizem Limnili², Nilgun Ozcakar¹

¹Department of Family Medicine, Dokuz Eylul University, Izmir, Turkey

²Medical Center, Dokuz Eylul University, Izmir, Turkey

Background&AIM:

Endometriosis is defined as presence of functioning endometrium outside uterus. Prevalent complaints are menstruation related nodule, pain and infertility. Medical or surgical treatment can be planned. Endometriosis rate is 10%-44% and seen commonly in ovaries. Usually seen in uterine environment but can also seen in distant tissues like rectovaginal septum tissue, cecum, ileum, the inguinal canal, abdominal and perineal scars, ureter, bladder and umbilicus. Abdominal wall placement is very rare. Majority of them developed in abdominal surgery, especially gynecological surgery scar tissue.

CASE:

A 33 year-old case (G1P1) of our clinic had left side ovarian endometriosis before pregnancy, was presented with a painful nodule 2 years after caesarean surgery. Nodule was located on the left side of abdominal wall. The patient told that it was getting bigger and painful with dysmenorrhoea during menstruation. In physical examination mass was palpated at superior part of Pfannenstiel incision, 5-6cm left side of midline, 4cm in size; fixed and painful. Gynecologic examination was normal. Ultrasound showed subcutaneous complex cystic and solid mass, size of 4x2cm. Diagnostic excisional biopsy was performed and revealed a yellow, irregular shaped solid mass; 4x2cm sized located in the subcutaneous region of the left pubis. Pathological diagnose was scar endometrioma. One month after the surgery complaints were lost. 3 months postoperatively, recurrence was not observed.

CONCLUSIONS:

There is an increase in endometriosis cases due to gynecological surgery. The pathophysiology of the scar endometriosis may be due to the direct implantation of the endometrial tissue in scars originated at operation, or induce the surrounding tissue to undergo metaplasia, alternatively, the endometrial tissue may reach the surgical scar through lymphatic or vascular pathway. In women with of abdominal masses on the front wall endometriosis should be kept in mind; the presence of previous surgeries and symptoms with menstrual periods supports diagnosis.

³TORRE PACHECO HEALTH CENTRE, MURCIA HEALTH SERVICE, SPAIN

BLACKGROUNDS AND AIMS

Based on the last Bethesda classification (1), in which ASCUS has been subdivided into two categories, ASC- H, as ASCUS suggestive of HSIL and ASC- US, as undefined ASCUS, we have reviewed 25 pathological cytologies throughout a year in our Health Centre, in order to unify the protocol for cervical cancer prevention in area 8, reminding that HPV is the main casual agent and sexually transmitted via.

METHOD:

This is a descriptive study, reviewing 1,379 cytologies performed for one year (November 17, 2013 to November 16, 2014) at San Javier Health Centre, using the G-STAT 2.0 statistical analysis.

RESULTS:

Source: Spanish 69.33%, 13.70%South American, 9.43% Arab and 7.54% rest of Europe. The month in which more cytologies are made is July: 11.02% and the least, 2.39%, in August. Cytological RESULT: normal 98.19%.

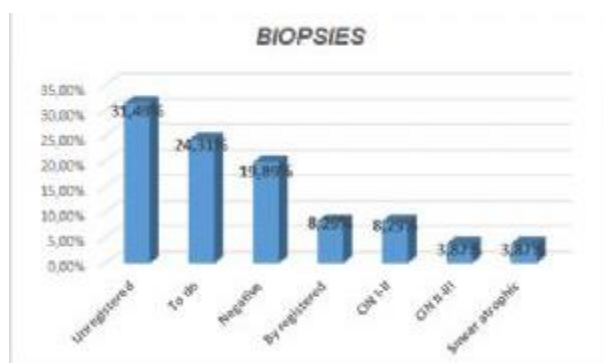

The average age of the pathological cytologies is 34.52 years. Diagnosis: 46.41% ASC, ASC-H 30.94%, 14.92% CIN-I and CIN-II 7.73%. Without a gynecological history: 60.22%, with a history of conization or CIN-I: 3.87%, respectively. 71.82% priority Inter-consultations to cervical pathology were made. From the ordered and registered HPV, 16.02% were positive; from this 3.87% were vaccinated for high risk. Regarding carried out biopsies; the 19.89% was negative, the 8.29% CINI-II and CIN3.87II-III. No surgical intervention was performed, 48.07%. In relation to the subsequent revision: after a month 16.02%, 12.15% 3 months, 6 months 3.87%, 3.87% 12 months, cytology control after 6 months 19.89%, 3.87% medical discharge; rest not registered.

CONCLUSIONS:

- 1.-The presence of ASCUS or AGUS on cytology does not necessarily mean malignancy.
- 2.-Without forgetting that although most of the time they correspond to benign alterations, this group of women have a higher risk of significant pathology. HPV screening cost efficacy can be an alternative to colposcopy.

Vascular remodeling caused by high blood pressure in premenopausal women

Adriana Simkova¹, Sona Kinova², Juraj Simko¹

¹Ambulance of general practitioner, Pezinok, Slovak Republic

²1st. department of internal medicine, Faculty of Medicine, Comenius University Bratislava, Slovak Republic

Arterial hypertension (AH) is one of the major risk factors (RF) affecting blood vessel and heart. The impact of classical RF is depend also on sex. Cardiovascular diseases (CVD) in women occur about 10 years later than in men.

Compliance of arteries in younger women is expected to be preserved to protective hormonal profile despite hypertension.

Our aim was to compare pulse wave velocity (PWVao), systolic blood pressure in aorta (SBPao), pulse pressure (PP) and index of left ventricle mass (LVMi) in premenopausal women with and without AH.

Patients and methods

From the cohort of 81 premenopausal women (without history of CVD), 26 (32%), mean age 42y had AH, control group 55(68%) women, mean age 39y without AH. Antihypertensive therapy (mainly RAAS antagonists) had 21 women, 5 were without treatment. PWVao and other hemodynamics parameters (SBPao, PP) were measured using Arteriograph-Tensiomed, which estimates global aortic stiffness. LVMi was derived from standard echocardiographic examination.

Results

The PWVao was significantly higher in women with AH (8,89m/s) comparing to a control group (7,79m/s). The differences of mean values of SBPao (135mm/Hg vs 112,29mm/Hg) and PP (57mm/Hg vs 47mm/Hg) were significantly different and both unfavourable in patients with AH. The difference in LVMi wasn't stistically significant. In mean age, there was no statistically difference.

Conclusion

The aortic compliance is lower in premenopausal women with AH. LVMi wasn't different significantly. Pathologic alternation of blood vessels probably occur earlier than in the heart.

Keywords: vascular remodeling, arterial hypertension, premenopausal woman

Stress - type urinary incontinence. What are the most common causes of stress incontinence in women?

Inga Evaltaite Budvytiene¹, Agne Sumilaite¹, Kazys Simanaukas¹, Sonata Bariliene²

¹Department of Faculty of Medicine: Clinic of Internal Diseases And Family Medicine, Vilnius University, Vilnius, Lithuania

²Lithuanian University of Health Sciences Hospital Clinics, Kaunas, Lithuania

BACKGROUND: Stress incontinence is a leading type of urinary incontinence and mostly it is an undiagnosed problem, especially by elderly women. Our study reveals the main risk factors for developing stress incontinence. **METHOD:** A prospective, limited time, cohort study was enrolled in 2014. 155 women attended, who were older than 18 years-old and were asked to fill in a questionnaire. In this study was used two forms: ""King's Health Questionnaire – KHQ"" , which was established by C. J. Kelleher and other authors in 1997 and adapted form, composed by medical doctor S. Bariliene in 2008.

Results from a study were analysed with a program ""SPSS"" and ""MS Excel2014"".

RESULTS: 155 women were examined, 23,87%(37) reported to have urinary incontinence problem. 34,19%(53) denied they have urinary incontinence, but as it showed later, they all faced this problem. Overall, the study demonstrated that 57,41%(89) of women need to cope with this problem. The results exposed that a stress incontinence was the most common type, 71,91%(64). It showed that the average age of women, who has stress incontinence is 45.86 years-old and this index is statistically reliable ($P=0,003$), when it was compared with healthy woman. Moreover, the results disclosed an inheritance factor is statistically reliable ($P=0,019$). There was a statistically reliable difference between woman who had delivered a child and the once who had not had ($P=0,006$). Indeed, the most revealing factor is that the number of labour, makes no difference for developing urinary incontinence.

In CONCLUSION: The possibility of developing stress incontinence increases with an age, particularly if the first-line relative has this problem. Another factor – the number of labour was investigated, it demonstrated there is no statistical difference between the number, but the fact that women had delivered a child, makes her chance of having a stress incontinence higher.

Keywords: Urinary incontinence, stress incontinence, cause factors.

Distribution of stress incontinence between different age groups.

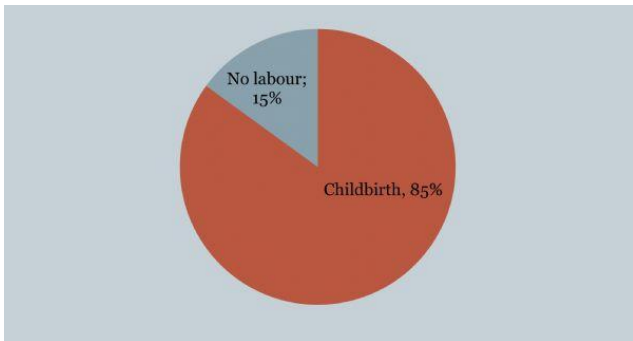

Distribution of stress incontinence is high in all groups. The average age of women is statistically reliable ($P=0,003$), when it was compared with healthy woman.

Inheritance role for developig stress incontinence.

Study revealed that 76% women had a family history of stress incontinence. An inheritance factor is statistically reliable (P=0,019).

Labour as a risk factor.

Study showed that 85% of women who delivered a baby have urinary incontinence. There was a statistically reliable difference between woman who delivered a child and the once who had not (P=0,006).

Prevalence of stress incontinence according a fact of delivery.

Stress incontinence	Childbirth	No labour
Positive (n= 79)	60% (n= 72)	21% (n= 7)
Negative (n= 76)	40% (n=50)	79% (n= 26)

Woman who had at least one child have nearly 3 times higher risk of developing stress incontinence than woman who have not.

Validity Of Breast Cancer Risk Analysis Models Gail, NCI And NSABP To Evaluate The Risk Of Turkish Women

Elif Altunbaş Ateş¹, Betül Bozkurt²

¹Department of Family Medicine, Karadeniz Technical University, Trabzon, Turkey

²Department of Breast and Endocrine Surgery, Ankara Numune Training and Research Hospital (ANTRH), Ankara, Turkey

Background&AIM: The best protection against breast cancer, which is the commonest cancer in women, is early detection. The breast cancer risk assessment tools most in use are the Gail model, the NSABP and NCI models. We studied a group of Turkish women with a previous diagnosis of breast cancer to ascertain if these models could be applied to Turkish women. Could we predict that they would have breast cancer?

METHODS: We retrospectively evaluated 1334 patients who had diagnosed breast cancer in ANTRH between April 1998 and December 2014. To evaluate Gail, NSABP and NCI models we collated the requisite parameters, age at diagnosis, age at menarche, age at first childbirth, history of previous biopsy, history of breast cancer in a first degree relative. We included patients whose 5 years risk, calculated by Gail and NSABP models was found to be greater than 1.67 as high risk for developing breast cancer. High risk patients calculated by the NCI model are those whose risk is greater relative to women of the same age with no risk factors.

RESULTS: In our study the Gail model identified 32.4 % of the patients who had a diagnosis of breast cancer as being at high risk. The NSABP model identified 19.3% as being at high risk and the NCI identified 20.1%.

DISCUSSION: Comparing the sensitivity of the three models the Gail model was the most sensitive; however it only identified 32.4% of those patients who developed breast cancer as being at high risk. When we compared these models we found that, although there is a correlation between the results, the results are significantly different.

CONCLUSION: As a result of the model's low sensitivity and poor concordance we conclude that these three models are not applicable to a Turkish women. There is a need to organize a new risk assessment model with addition of different parameters to validate Turkish women.

The Relationship Between Sex Hormone Binding Globulin and Metabolic Syndrome Parameters with Obesity in Premenopausal Women

Seher Sayın, Ruhuşen Kutlu, Fatma Gökşin Cihan

Department of Family Medicine, Meram Medical Faculty, University of Necmettin Erbakan, Turkey

Background and AIM: Metabolic syndrome (MetS) includes the abdominal obesity, hypertriglyceridemia, low high-density lipoprotein (HDL) concentrations, hypertension, and hyperglycaemia. Sex hormone binding globulin (SHBG) is the major binding protein for gonadal steroids in the circulation. The aim of this study was to determine SHBG and MetS parameters concentrations in premenopausal women and to evaluate the relationships between these parameters with obesity.

METHOD: This study was carried out on 150 premenopausal women referred to the Outpatient Clinic of Family Medicine, Meram Medical Faculty Hospital. Patients were divided into three groups according to the body mass index: normal-weight, overweight and obese women. The blood pressure was measured. Low-density lipoprotein cholesterol (LDL-c), high-density lipoprotein cholesterol (HDL-c), total cholesterol (TC), triglyceride (TG), fasting blood glucose (FBG) and SHBG levels were examined in the blood samples of the patients. Fat distribution and body compositions were assessed with a portable impedance analyzer (Tanita®). One way ANOVA and Pearson correlation tests were used to determine relationship between variables. All statistical analyses were performed using SPSS 20 software. P value less than 0.05 was considered as significant.

RESULTS: The mean age of the patients was 31.37 years (SD=8,33). The mean age was similar between the groups (p=0.097). In the obese group, FBG (p=0.000), LDL-c (p=0.001), HDL-c (p=0.001), TC (p=0.009), TG (p=0.002), uric acid (p=0.000), systolic (p=0.000) and diastolic blood pressure levels (p=0.017) were significantly higher than non-

obese group. In the obese group, SHBG levels was significantly lower ($p=0.005$). A significant negative correlation was found between the SHBG levels-fat percentage ($r=-0.206$, $p=0.012$) and SHBG levels-waist circumference ($r=-0.237$, $p=0.003$).

CONCLUSIONS: These results suggest that low plasma SHBG level may represent a significant predictor of the obesity in premenopausal women.

Keywords: Metabolic syndrome, sex hormone binding globulin, premenopausal woman.

Bilateral galactorrhea: more than a pregnancy?

Ana Sofia Rocha, André Pereira Lourenço, Inês Espiga Macedo, Pedro Moreira Castro
USF Modivas, ACES Póvoa de Varzim/Vila do Conde, Porto; Portugal

Background

Galactorrhea is a common breast complain. If bilateral it is frequently caused by lactation, physiologic galactorrhea or hyperprolactinemia, which may be due to medication, endocrine tumors or abnormalities.

Case report

A 23-year-old female, living in consensual union, graduated, nurse. Belongs to a nuclear family, Duvall cycle I, Graffar classification II. No premorbidities or significant family history.

In June 2014 she came to the family doctor for a preconceptional consultation, which was entirely normal. Returned in August 2014 with complaints of galactorrhea for the past week, performed a pregnancy test which came back negative. She denied taking medication or any history of substance abuse. Physical examination showed a serous bilateral nipple discharge and no other findings were presents. Laboratory tests revealed an elevated serum prolactin, normal thyroid function and a normal mammary ultrasound. CT scan imaging of the brain was then performed and showed a pituitary mass with 3.5 mm diameter. She was referred to endocrinology which only took place in January 2015. Meanwhile she became pregnant and at the time of the consultation she already had a thirteen weeks pregnancy. Further study through brain MRI and treatment decisions were postponed until the postpartum period. Despite being a health professional she is very anxious and fearful dealing with two life-changing situation at a time.

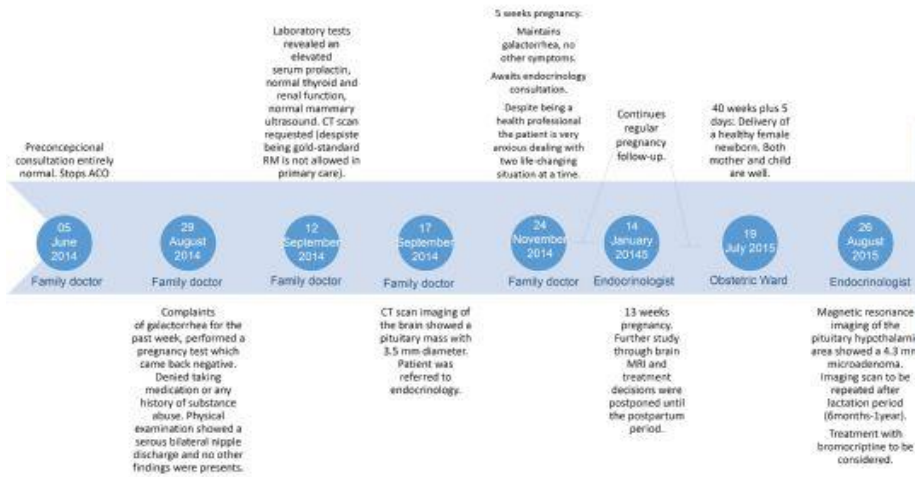

Discussion

Family doctor is usually the first contact within the health care system and must deal with all kind of medical problems. In this case it means not only to recognize and diagnose the disease but also to deal with the pregnancy and psychological allocation of the patient. This case exposes the importance of the holistic approach and how the life circumstances of our patients affect their sense of illness.

Keywords: galactorrhea, pregnancy, pituitary adenomas, illness

Assessment of the risk factors influencing osteoporosis in patients who were admitted to outpatient menopause clinic

Ahmet Gürhan Poçan¹, Çiğdem Gereklioğlu¹, Kenan Topal², Süheyl Asma¹

¹Baskent University Medical Faculty, Family Medicine Department, Ankara/Turkey

²Adana Numune Training and Research Hospital, Family Medicine Department, Adana/Turkey

BACKGROUND and AIM: To investigate the risk factors affecting osteoporosis in patients who were admitted to outpatient menopause clinic and to determine their relationship with osteoporosis.

METHOD: The association between postmenopausal osteoporosis and history of pregnancy, oral contraceptive (OCS), antiresorptive, calcium, hormone replacement therapy (HRT) use, smoking, alcohol and caffeine consumption, diet and physical activity were questioned in 1139 patient. Total BMD of the femur and lumbar spine were used for statistical analysis and T scores above -1 were accepted as normal, between -1 and -2,5 as osteopenia and -2,5 and below as osteoporosis according to WHO criteria. Two independent sample t test, One Way Anova, Chi-square test and Logistic Regression Analysis were applied.

RESULTS: Mean age of the patients was 53.5±6.7 years. Mean duration of menopause was 7.1±6.2 years (range 1-31), mean age of menopause was 46.3±5.1 years. While 88.6% of the patients had natural menopause, 11.4% had surgical menopause. Mean BMI was found as 29.6±5.1. Femur and lumbar BMD (p= 0.000, p= 0.003) and T scores (p= 0.000, p= 0.000) of these patients were found to be statistically significantly higher than those of the patients with normal weight and increase as BMI increased. Femur T scores were seen to be influenced by OCS (p=0.035), HRT (p=0.003), antiresorptive treatment (p=0.000) use, caffeine consumption (p=0.020), history of fragility fracture (p=0.025), BMI (p=0.000). Lumbar T scores were seen to be influenced by menopause type (p=0.047), HRT (p=0.038) antiresorptive treatment (p=0.000), smoking (p=0.036) and BMI (p=0.000).

CONCLUSION: Femur and lumbar T scores were found to be lower in patients with normal or low BMI and who are smoking. The scores were higher in patients who had previously used OCS and currently using HRT, who regularly consume dietary calcium. Early detection of particularly modifiable risk factors may reduce osteoporosis risk.

Does family planning method changes according to birth place?

Binali Çatak¹, Can Öner²

¹Kafkas University School of Medicine

²Istanbul Bilim University School of Medicine

Unmet need for contraception can lead to unintended pregnancies. To use contraceptive methods which are mainly related with sociodemographic features and service-related barriers. Policy-makers can only strengthen contraceptive programs by using data on barriers of contraceptive use. The main objective of this study was to compare use of contraceptives in two groups of women: Home delivered and hospital delivered women.

The data of this study was derived from part of prenatal and postpartum care of an other study namely "Unplanned home birth and affecting factors". This study was designed as case control study. The "case" group consisted of 229 women who had "unplanned home deliveries" and "control" group (n=458) of women giving birth in hospitals. The data were analyzed in the SPSS package program

Mean age of case group was 26,5±6,1 years, and control group was 27,5±5,3 year (p=) The median of total pregnancy count was 2 (1-9) and 1 (1-10) in case and control groups respectively. On the other hand median of lived children count was 3 (0-9) in case group and 2 (1-10) in control group. Unintended pregnancy rate was 20,8% (n=36) in case group where as it was 9,6% (n=37) in control group.

Contraceptive non users rate reaches up to 40,5% in case group and 42,5% in control group before delivery and decreases in both groups 24,3% and 25,3% after delivery. In both groups only one thirds of women used modern contraceptive techniques before delivery (27,7% vs 30,6% case and control groups respectively). After delivery the use of modern contraceptive techniques increases in both groups but there was no significant difference between groups (39,3% vs 43,8% case and control groups respectively).

There is no difference between use of contraceptives before and after delivery in women who delivered home and hospital.

Keywords: family planning, home birth, contraception

The frequency of cesarean sections in primiparous women and affecting factors: cross-sectional type field study

Binali Çatak¹, Can Öner², Sevinç Sütü³, Selçuk Kılınç³

¹Kafkas University School of Medicine

²Istanbul Bilim University School of Medicine

³Burdur Public Health Directorate

In Turkey parallel to the developments in the World this rate has risen to 48.1% in 2013. The purpose of this study is to determine cesarean birth rates and to find out factors affecting the cesarean birth in primiparous women. The universe of the research this cross-sectional type was formed by 223 primiparous women. The data was collected with data collection form prepared by the researchers using face-to-face interview technique. In these analyses, chi-square and Backward LR logistic regression analyses were used.

In multivariate analyses, the place of delivery (OR: 11.2 [2.9-42.46] in private hospital and OR: 6.1 [2.6-14.1] in university hospital); time of the birth (OR: 7.1 [3.1-16.0]); doctor's effect (OR: 4.0 [1.8-8.95]) and husband's employment status (OR: 2.23 [1.0-4.7]) have been identified as factors affecting the caesarean delivery among these factors.

Although the results don't show all of the factors affecting the caesarean delivery in primiparous, they also reveal that medical reasons are not the only reason in this increase trend. Health policy makers and health professionals are required to identify the causes of this increase and to take measures.

⁵Department of Family Medicine, 4th Air Force Base, Ankara, Turkey

⁶Department of General Surgery, TOBB ETU Hospital, Ankara, Turkey

⁷Department of Internal Medicine, Gulhane Military Medical Faculty, Ankara, Turkey.

Background & AIM: Breast cancer (BC) is the most-common malignancy of women worldwide. Though slight difference among developed and developing countries, BC remains as the most common cancer type of women in Turkey. This study aimed to identify the level of knowledge, awareness, and their potential predictors towards BC in Ankara, Turkey.

METHOD: The present descriptive study was conducted on 376 females attending to a breast health outpatient clinic. Self-administrative questionnaire was designed to evaluate knowledge level about BC and predictors effecting its level. Data analysis was performed using the chi-square test. A value of $p < 0.05$ was considered statistically significant.

RESULTS: Mean age of the participants was 46.16 ± 9.93 (22-75). Majority (92.6 %) were married; 41.5% educated less than nine years. Most of the women were housewives (82.7%) and, were living in the urban region (86.4%). Predictors of effecting responses to seven knowledge and awareness questions about BC vary from demographic features including older age groups, higher educational levels, being married, living in an urban area, being employee, smoking, having greater BMI to additional attributes associated breast health such as the increased number of births, applying for the purpose of control, positive family history of breast diseases, any diagnoses of breast diseases and performing BSE practice.

CONCLUSION: It was determined that females in Turkey have better knowledge of BC than other developing countries even though it is not in the desired level. These findings revealed that females should be more informed about BC risk factors, prognosis and treatments by primary health-care providers to get through the ascending burden of this disease.

Knowledge, Attitude And Practice Towards Osteoporosis Among Young Women

Asım Koç, Cenk Aypak, Hülya Yıkılkan, Derya İren Akbıyık, Süleyman Görpelioğlu

Department of Family Medicine, Dışkapı Yıldırım Beyazıt Training and Research Hospital, 06110 Ankara, Türkiye

Background & Aim

Osteoporosis (OP) is a global health problem. The disability due to OP is greater than that caused by cancers and is comparable that lost to a variety of chronic non-communicable diseases.

It is intuitive that primary preventive measures including early detection of risk factors for OP, educating the individuals at risk on preventive measures, and timely intervention will reduce the morbidity and mortality.

Therefore, we aimed to evaluate the knowledge, attitude and practice towards preventing OP among young Turkish women.

Methods

This study was carried out among 18-35 years old females who attended to outpatient clinics of Family Medicine Clinic in Dışkapı Yıldırım Beyazıt Training and Research Hospital. A questionnaire was used to assess knowledge, beliefs, and practices towards OP. The questionnaire to assess practices related to OP included questions on positive and negative behaviours towards OP. The positive behaviours assessed were dietary calcium intake, physical activity and exposure to sun. The negative behaviour assessed was on smoking status.

Results

A total of 218 women (mean age= 26.2 5.6 years) enrolled in study. The median score of knowledge about OP was 40, out of a total score of 100. The knowledge revealed that, 138 (63.3%) had a poor score and 80(36.7%) of the participants had a good score. In the group who had high knowledge score than median (n=80); 30% (n=24) were smokers, 8(10%) were not exposed to the sun for at least 10 minutes a day and 56.2% (n=45) of the participants achieved the Recommended Daily Allowances (RDA) for Calcium. 64 (80%) were not engaged in the recommended exercises in type and duration.

Conclusions

Awareness for OP was low and practices towards preventing OP were inadequate. An immediate need exists to promote osteo-protective lifestyle practices among young women.

AIM: The health belief model is one of the models, used widely in understanding and explaining the person's attitudes and behaviors toward early detection. This study was aimed to determine the behaviors and beliefs, influencing breast cancer early detection in the content of health belief model.

MATERIALS-METHODS: The research has been planned in a descriptive nature with the population of the research constituted by the 126 women healthcare professionals who work at the University Hospital. Research data were collected by a data form which was included sociodemographical characteristics and Champion's Health Belief Scale. The scale assesses health beliefs components such as perceived susceptibility, perceived benefits of mammography screening, and perceived barriers to mammography screening. Data were analyzed with mean and percentage values, Mann Whitney U and Kruskal Wallis H tests on SPSS version 18.0 package program.

RESULTS: The mean age of women were 30 ± 6.8 years, 52.3% were married, 88.8% had high school graduates, and 52.3% were nurses. The results determined that 28.6% of the women had their regular breast self-examination (BSE) monthly, 21.4% had breast cancer in the family, 83.3% received BSE education, 55.6% of them received education before graduation. There was a significant difference in the scores on barriers between the of women healthcare professionals' who performed BSE and those who did not perform BSE and perceived barriers was low ($p < 0.02$). However, there was no statistically significant difference in the scores on benefits, confidence, susceptibility, seriousness, and health motivation between the groups and subscale scores was found to be high.

CONCLUSION: The results of this study showed that beliefs were effective on BSE performance.

Women Protected with two IUDs for 10 years: A Case Report

Engin Burak Selçuk, Şule Barış, Burcu Kayhan Tetik

Department of Family Medicine, Inonu University Medical Faculty, Malatya, Turkey

Family planning includes all of the services given to families to provide them to decide to when and how many children they would have. Intrauterine devices (IUD) are one of the widely used family planning methods, in our country.

CASE: A 54-year-old, multiparous woman patient, had admitted to a healthcare institution and had an IUD inserted, as a method of birth control, 15 years ago. Then, when the patient admitted to a primary health care facility for routine smear control, 10 years ago, they couldn't visualize the removal string of the IUD and thinking that the first one had dislocated, inserted a second IUD, without taking a direct radiograph. Then the patient had admitted to a healthcare clinic to have the IUD removed, upon reaching menopause, last year. After removing the device, they obtained a direct radiography. They observed image of another IUD on the radiograph and it was understood that the woman had been carrying two devices since long time. The patient was referred to gynecology outpatient clinic of our hospital. In clinic the string of the IUD couldn't be visualized by speculum examination. Echo of the IUD was defined in the uterus with ultrasonography. The device couldn't be removed in the outpatient conditions and hysteroscopy planned. During hysteroscopy, the IUD was found to invade the myometrium. The patient underwent total abdominal hysterectomy - bilateral salpingo-oophorectomy

CONCLUSION: The family planning services are one of the most important parts of the preventive health services. As prescribed by the evidence, the patients should be monitored at regular intervals, they should be informed and complications should be discussed at every visit, and the next appointment should be planned. Updating the family physicians' knowledge about family planning periodically will contribute to the learning new methods as well as preventing possible complications.

Eating Disorder in Emergency Department

Veronica Parent Mathias¹, Juan Maria García Lopez¹, Lorea De Unamuno Lumbreras², Irina Yezerska³, Ana Rando Jimenez¹, Raquel Gomez Bravo⁴

¹Department of Emergency of Regional Hospital, Málaga, Spain

²Andalusian Public Health Service, Spain

³Cantabria Public Health Service, Spain

⁴Semfyc, Spanish Family Medicine Society, Spain.

Background. Case

16 year old brought to the emergency department of AP by unconsciousness while she was dancing. Before she comments her partners dizziness, but not palpitations or visual disturbances.

She Refer cramps and headache in the past two weeks. Six months ago presented an episode of abdominal and precordial pain. 5/30 menstrual cycle, but 8 months ago it disappear. Very good student, above average ratings. She has many friends and social relationships. Recent divorce of parents. Good student in the dance academy which since seven years ago, she loves dance and she refers the mother to be a professional.

Method

We conducted a clinical interview when she arrive at our Emergency Department. In the physical examination was highlighted a pale skin, thinness and The body mass index¹⁶. Tanner 3.

Asymptomatic when she arrived, we decided to refer the following analitic dates to her Family Physician because we suspect a disorder in her Eating behaviour.

RESULTS:

Potassium 2.5 mEq / L

CO₂: 29 mEq / L

Calcium: 8.2 mEq / L

Phosphorus: 4.2 mEq / L

A history of chest and abdominal pain can be able to a possible esophagitis, which may be secondary to vomiting. Amenorrhea by excessive exercise, caloric restriction and loss weight. La hypokalemia and / or low levels of ionized calcium can be the cause of cramps, headache, dizziness and heart rhythm disturbances.

Treatment and Action Plan

Requires family education, nutritional counseling and psychiatric treatment. It is derived endocrinology and to our Mental Health Unit.

CONCLUSIONS

Eating disorders appears in adolescents above 14-18 years. Clinics and a good doctor-patient relationship is essential to reach the diagnosis. The goal of the therapy in patients with Ealing disorders is to get weight regain and the own awareness of the disease.

Body composition and Eating Disorders in a woman risk population

Veronica Parent Mathias¹, Jose Ramon Alvero Cruz², Jeronimo Garcia Romero², Francisco Rivas Ruiz³

¹Emergency Department Regional Hospital, Málaga, Spain.

²Department of Sport Medicine, Andalusia Tech, Malaga University, Spain.

³Research Unit, Costa del Sol Hospital, Marbella, Malaga, Spain.

BACKGROUND AND AIM: Eating disorders (ED), anorexia nervosa (AN), bulimia nervosa (BN) and its variants are significant mental health problems affecting mainly young women and can become severe disorders, high mortality and dysfunctionality, especially students and dance professionals (risk population). For a family physicians is crucial the early diagnosis of an ED.

To determine in our risk population the sensitivity and specificity of body mass index regarding the diagnosis of eating disorders.

METHOD: We have studied 81 students of dance, women 13.3 ± 3.2 years, weight 45.4 ± 9.9 kg, height: 151.3 ± 12.1 cm and body mass index: 19.6 ± 2.3 kg / m². BMI was calculated conventionally. We used the EAT-26 questionnaire, administered to evaluate the ED with three subscales (dieting, bulimia and oral control). A statistical study was performed using the Spearman correlation coefficient, after rejecting the normality of the variables. Further analysis using ROC curves (Receiver Operating Characteristics), allowed to determine the sensitivity and specificity of BMI for the diagnosis of TCA. MedCalc for Windows program was used and a level of significance was set at all analyzes of $P < 0.05$.

RESULTS: The weight (Rho: -0.236) and height (Rho: -0.31): Significant correlations with age and bulimia subscale (-0.28 Rho) are found, all $P < 0.05$. ROC curve analysis, found values of area under the curve (AUC) of the BMI 0.56 ($P > 0.05$). The sensitivity and specificity (S / E) of the variable are 30% / 98%.

CONCLUSIONS: The BMI has not the highest sensitivity and specificity for the diagnosis of eating disorders. Based on the results, we suggest to study other variables of body composition to control the ED. The weight and height has a significant correlations with the age and bulimia subscale, so BMI can be used in this subscale.

Is imaging necessary in women with mastalgia?

Mehmet Arslan¹, Halime Seda Kucukerdem¹, Huseyin Can¹, Ercument Tarcan²

¹Izmir Katip Celebi University Ataturk Training and Research Hospital, Family Medicine Clinic, Izmir, Turkey

²Izmir Katip Celebi University Ataturk Training and Research Hospital, General Surgery Clinic, Izmir, Turkey

Background-AIM: Mastalgia is the most common symptom in women, who has gone under breast imaging. 70% of women faces with mastalgia at least once in their lifetime (1,2). In our study, we aimed to investigate the examinations and the results of the females referred to our outpatient clinics with mastalgia and to determine the frequency of malignancy.

METHOD: Files of all the patients referred to IKCU Ataturk Training and Research Hospital General Surgery Outpatients Clinics between June - November 2014 has been investigated retrospectively. Cases only with breast pain complaint (n=308) out of 1396 women has been included in the study. Women with lump in breast, nipple discharge, redness, breast retraction and similar symptoms and pregnant and lactating women were excluded. Breast examination findings, ultrasonography (USG) and mammography results and whether biopsy is done or not has been investigated. Descriptive data has been given as mean±standard deviation (minimum-maximum values) and percentage (number).

RESULTS: Mean age was 42.4 ± 11.9 (16-74) years. 57.5% (n:177) of the women were over 41 years old, 57.5% (n:177) had bilateral mastalgia. 91.9% of the breast examinations were found to be normal. USG was required from 267 (86.6%) women but 51 (16.5%) of them didn't undergo. Out of 182 (59%) women that has been required mammography, 32 (%10.3) women didn't undergo. Pathologic investigation was required from 23 (7.4%) patients. Considering diagnoses; fibrocystic changes in 27.3% (n:84), ductal ectasia in 8.1% (n:25), fibroadenomas in 4.9% (n:15), reactive lymphoid hyperplasia in 1% (n:3) was observed. Only 1 (0.3%) woman was diagnosed with invasive ductal carcinoma.

CONCLUSION: According to researches, 0.5% of the women with mastalgia were diagnosed with breast cancer (2). In our study this rate was found as 0.3%. Considering these results, it is suggested that breast pain is not an important symptom of breast cancer.

Approach and Treatment of Female Urinary Incontinence in Primary Care: a Protocol

Nuno Namora, Maria João Abreu, Luísa Feraz, Fernanda Rodrigues
 USF DuoVida - ACES Alto Ave, Portugal
 Background

Urinary incontinence (UI) is a common symptom, which can dramatically influence the physical, psychological and social well-being in affected individuals. The UI represents an important challenge for General Practitioners (GPs). Considering that the majority of patients are not treated, GPs are at the ideal position to track and address the UI. The UI prevalence increases with age and affects more women than men (2: 1). Most UI are classified as stress, urge, or mixed (combination of both symptoms).

Aim

Systematize, given the current evidence, the more appropriate diagnostic approach and treatment of female urinary incontinence in Primary Health Care.

Set recommendation standards for GPs regarding indications for referral.

Methodology

It was performed a literature review of clinical guidelines published from 2009 to December 2014, using the following keywords: urinary, incontinence, women.

Results

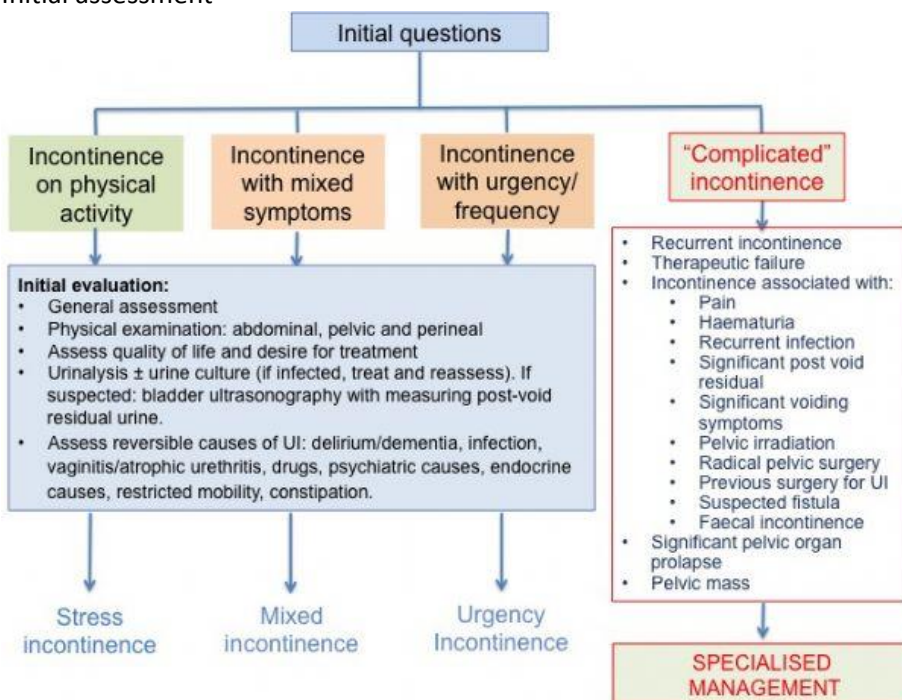

In most cases, a correct anamnesis of the patient is enough to distinguish the type of incontinence and select the cases with complicated incontinence, which requires a referral immediately. In the case of stress and urge incontinence, empirical treatments such as lifestyle changes, treatment of reversible causes of UI, training of the pelvic floor muscles, bladder training and treatment of atrophic vaginitis should be initiated. If not effective, a specific pharmacology treatment should be prescribed according to the type of incontinence. In case of failure thereof, the patient should be referred to secondary health care.

Discussion

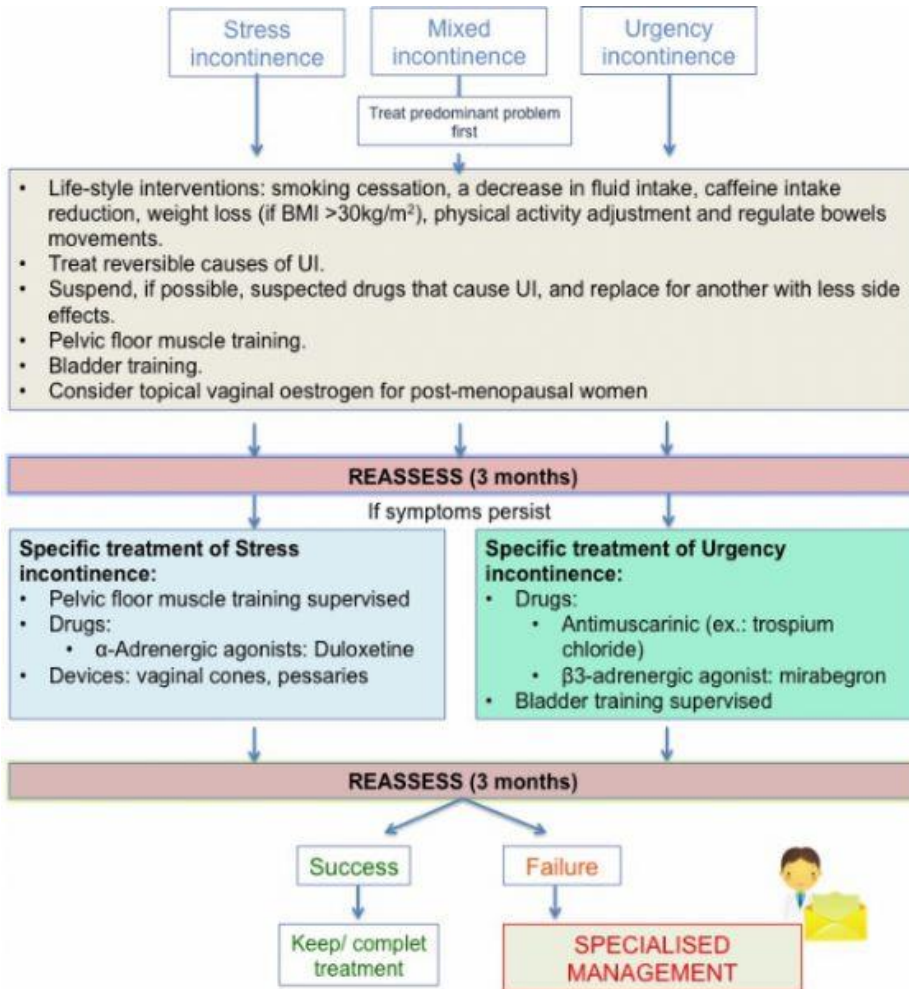

A flowchart approach and treatment of urinary incontinence can contribute to help GPs to address this problem, and more importantly, improve the quality of life of patients.

Vulvar lichen sclerosus approach in Primary Health Care

Hugo Ribeiro¹, Mariana Fonseca², Elisa Paredes³

¹Personalized Health Care Unit Barão do Corvo, Health Centers Group Grande Porto VII, Vila Nova de Gaia, Portugal

²Family Health Unit Anta, Health Centers Group Grande Porto VIII, Espinho, Portugal

³Department of Gynecology and Obstetrics, Hospital Center of Vila Nova de Gaia/Espinho, Vila Nova de Gaia, Portugal

Background and AIM:

Vulvar lichen sclerosus is a benign, chronic, progressive dermatologic condition, with an unknown etiology and an estimated range of 1 in 300 to 1000 women.

The aim of this review is to highlight the importance of early diagnosis and treatment of vulvar lichen sclerosus in Primary Health Care.

METHOD:

A review was performed for papers published between January 2005 to March 2015, in Portuguese/English, in the medical databases Medline/Pubmed and Cochrane Library.

RESULTS:

Vulvar lichen sclerosus diagnosis is based on characteristic clinical manifestations, such as vulvar pruritus, anal discomfort, dyspareunia and dysuria. Typically, it is expressed as white, atrophic papules that may coalesce into plaques.

This pathology can result in physical dysfunction and impaired quality of life. Some studies have suggested that distortion of vulvar anatomy can be prevented if treatment is initiated early in the course of the disease.

The initial management of vulvar lichen sclerosus involves patient education and medical therapy. Although many treatments have been suggested to treat it over the years, only potent or ultra-potent corticosteroids remain as the treatment of choice.

Referral to a specialist is indicated when a patient does not respond after a six months empiric therapy, when there are doubts about the diagnosis or when a vulvar intraepithelial neoplasia or carcinoma is suspected.

CONCLUSIONS:

Vulvar lichen sclerosus is an often misdiagnosed, delay diagnosed and mistreated gynecologic disease. Biopsy is rarely needed to diagnose this pathology, so family physicians are in a privilege position to early diagnose and treat this condition, preventing physical dysfunction and impaired quality of life.

Life Quality Assessment among Woman with Urinary Incontinence

Daiva Puskoriute¹, Kazys Simanuskas¹, Sonata Bariliene²

¹Vilnius University, Faculty of Medicine: Clinic of Internal Diseases And Family Medicine, Vilnius, Lithuania

²Lithuanian University of Health Sciences Hospital Clinics, Kaunas, Lithuania

INTRODUCTION:

Urinary incontinence (UI) is a common, distressing and embarrassing problem. It has a big impact on the quality of life. It affects not only physical health, but also limits daily activities, mental and sexual life, has a strong impact on economic well-being as well. The research was done to assess how UI affects women's lives.

METHODS:

The research was done by anonymous questionnaire among women older than 18 years old. It had 56 questions and a block of 'King's Health Questionnaire' questions. Quantitative analysis was done by using SPSS 20.0 and MS Excel 2007. The survey was conducted in Vilnius Antakalnis polyclinics in 2014 years.

OBJECTIVES:

- to assess the impact of UI on women's daily activities, physical, mental and sexual health.
- to estimate the impact of UI on women's economical well-being.

RESULTS:

84 out of 289 women had UI and 95 % of the women with UI stated that urinary incontinence has moderate, big and very big impact on their lives. Women who do not have urinary incontinence rated their general health at the higher level than women with UI ($P < 0,05$). Also, women with UI had higher costs related with their health status ($P < 0,0001$). The highest impact of UI was on sleeping at night and reduced energy level during the next day, sexual activity, communications with friends and relatives ($P < 0,0001$).

CONCLUSIONS:

UI has a negative impact on the women's life quality. It affects negatively their daily life, physical activity, personal relationships, limits social life, disturbs sleeping, causes negative emotions. UI causes additional financial costs, and therefore has a significant impact on the women's economic situation.

We report the case of a patient of 32 years referred to the Unit Lower Genital Tract with HSIL cytology and vulvar warts. In clinical interview relates the beginning of sex at 18 relationships, and reports that he has had about 60 sexual partners in the past 3 years (over 30 in the last year), not consistently used condoms, no current stable partner and is an ex-smoker. Plan with Mirena. 4 years wearer ACO was a year ago. It is not vaccinated for HPV. Colposcopy in which an atypical transformation zone type 2 acetowhite epithelium and extensive areas of mosaic grade 2. In the vulvoscopy was observed multiple warts were observed in the labia and in the perianal area.

Were also performed cervical biopsy a microlegrado. Preoperative treatment was requested and instill it with Sinecatechins for vulvar warts. With histological diagnosis of HSIL in cervical conization was performed. The

patient was cited one month after starting treatment with Sinecatequinas. He said that the response had been very good with disappearance of most of the initial warts, a fact that was observed on physical examination. However it was observed a large inflammatory and edematous reaction entire vulva although completely asymptomatic. The table was classified as allergic reaction to treatment and was prescribed topical treatment with corticosteroids. At 3 weeks the normal vulva with 3 Residual warts was observed. In conclusion, one can say that Sinecatechins are an effective tool for the eradication of vulvar warts. In our experience tolerance is good as q increases adherence. Allergic reactions, as described in this case report, are rare.

spontaneous twin pregnancy in a bicornuate uterus

Ana Filipa Leite Abreu¹, Maria Inês Araujo Antunes²

¹usf physis, vizela, portugal

²usf ponte, guimarães, portugal

Background & AIM:

The felling fusion of Müllerian ducts results a failure in embryonic development and occur in 0.1-3% of fertile women. The most common is the bicornuate uterus, malformation characterized by the existence of two uterine bodies connected to a common cervical channel. Inherent to this occurrence are several anomalies, however they all have a common outcome: variations in standard fertility patterns for age.

METHODS:

Clinical interview and clinical process consultation

RESULTS: Case report

31 years old multiparous woman, without infertility history, who uses a query in our Family Health Unit (USF Physis) to start a pregnancy monitoring plan. The anatomic malformation was diagnosed in youth. Against all odds both pregnancies occurred spontaneously. The 3-D ultrasound confirmed the presence of two amniotic sacs, one in each uterus. The gestational age of each fetus was respectively 6 weeks and 4 days and 3 weeks and 2 days. This fact proves the existence of different fertilization times for each fetus. It was decided to send the patient to the referral hospital as a risk pregnancy for directed care. Actually with 20 weeks, the prenatal course follows uncomplicated for mother and babies. Due to the current knowledge and patient obstetric history, the babies should be delivered by elective bilateral low transverse caesarean section.

CONCLUSIONS:

A spontaneous twin pregnancy in this context is rare and cases of term pregnancy for both fetuses are almost nonexistent. Once these cases are very rare, there is no uniform guideline to manage them appropriately. For this reason a timely diagnosis and an optimal prenatal care are essential. Due to proximity between family physician and patient, the knowledge of such cases and possible complications minimizes the risks from a non planned pregnancy.

Physical, psychological, and menopause-related symptoms in a community-based sample of Turkish Women

Özlem Onur Köse¹, Dilsad Save², Alper Baba³, Orhan Gündüz⁴

¹Turkish Republic of Ministry of Health, Directorate of Istanbul

²Marmara University, School of Medicine, Department of Public Health

³Izmir Institute of Technology, Department of Civil Engineering, Izmir, Turkey

⁴Dokuz Eylul University, Department of Environmental Engineering, Izmir, Turkey

Background & Aim

Although menopause is one of the most important period in women health, the studies exploring association of individual factors such as obesity, lipid, cotinine levels, environmental factors and menopausal symptoms were in limited numbers. This study is designed to determine menopause prevalence and the relations between environmental and individual factors at over 45 years aged women in rural and urban religion.

Method

This is a cross sectional study which has been performed on a 542 women population at over 45 years aged. living in Çanakkale, Çan and Bayramiç district. Face to face questionnaire were applied and blood samples were collected. The questionnaire was consisted of socio-demographic characteristics, reproductive health issues and Menopause Rating Scale for menopausal symptoms assessment. The study was supported by the Scientific and Technological Research Council of Turkey (TUBITAK- ÇAYDAG- 106Y041).

Results

Participants average age was 60,5±10,2. Average age of menarch was 13,9±1,5 and for menopause was 45,6±5,8. Of the women 82% were postmenopausal. The most common menopausal symptom was joint complaints with

38%, and then sexual complaints with 37%. Menopausal complaints were more severe in rural region. Of the women 51% were obese and morbidly obese. The complaints were severe in overweight women. The level of Total Cholesterol were high in postmenopausal women (213±43). There were no relation between cotinine and menopause. The level of lead decreased over 10 years of menopause.

Conclusions

The study group were consist of obese, high cholesterol level women. The majority of women experienced mild or severe complaints but did not seek for health care. The health services must be accessible in all units of country and women must be counselled for gaining health promoting behaviour.

Keywords: menopausal symptoms, environmental factors, individual factors, urban/rural, health-care

{Prenatal Screening}

Marta Sousa Santos¹, Lisete Aires Silva², Joana Andrade Barros², Simão Martins³, Umbelina Mesquita⁴

¹UCSP Boticas, ACES Alto Tâmega e Barroso, Portugal

²USF Terras Souza, ACES Tâmega 2 - Vale Sousa Sul, Portugal

³USF Hygeia, ACES Tâmega 3 - Vale Sousa Norte, Portugal

⁴USF Torrão, ACES Tâmega 3 - Vale Sousa Norte, Portugal

BACKGROUND & AIM: Prenatal diagnosis (PND) is the performance of procedures for determining whether an embryo or fetus is a carrier or not of congenital anomaly. PND includes Prenatal Screening (PNS).

PNS is used for diseases such as Down Syndrome or Trisomy (T) 21, Edwards Syndrome (T18) and Patau Syndrome (T13), but T21 is by far the paradigm of PNS, given its prevalence and relevance in social and public health. The aim of this work was to review the literature on PNS performance.

METHOD: Research in the main medical articles databases, guidelines and cross- references.

RESULTS: The 1st trimester of pregnancy is the period indicated for the performance of PNS.

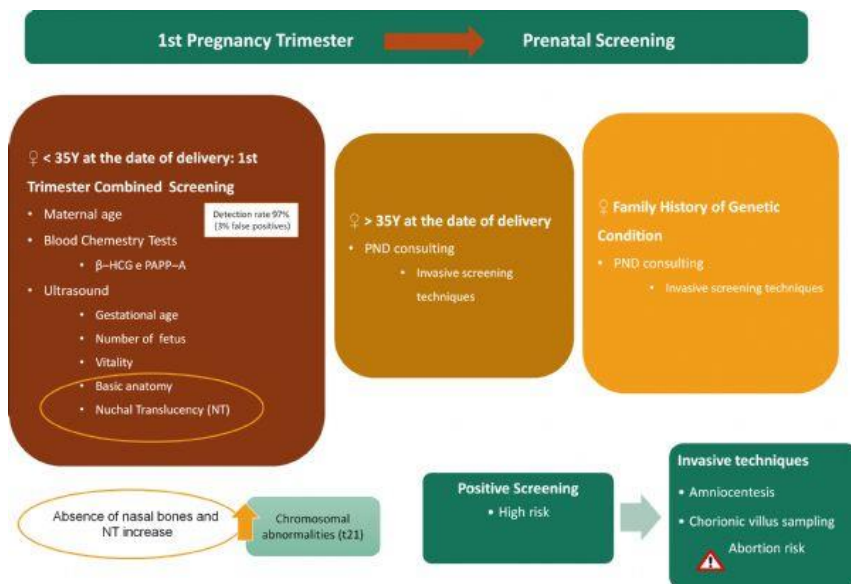

Women under 35 years at the date of delivery shall perform the combined screening of the 1st trimester. This includes maternal age, ultrasound and blood chemistry tests, and is currently accepted as the best method. The biochemical markers used are β subunit of human chorionic gonadotropin and pregnancy-associated plasma protein A. The ultrasound, among other parameters, evaluates nuchal translucency, which value, when increased, is associated to chromosomal abnormalities, including T21, as well as the absence of nasal bones.

When the screening is positive, based on a high risk, invasive techniques of screening are indicated as amniocentesis and chorionic villus sampling.

Women over 35 years at the date of delivery should be referenced to a PND consulting, as well as those with a family history of genetic condition, to perform invasive diagnostic techniques.

CONCLUSIONS: The 1st trimester combined screening is indicated for all pregnant. Most of the time the prenatal screening has a negative result which will provide a smooth pregnancy.

Do You Prefer Preconception Care Instead of Prenatal Care for Primary Health Care

Sultan Oksuz Zortul, [Ozlem Ozer](#)

Department of Family Medicine, Ataturk University, Erzurum, Turkey

Worldwide, maternal and child health faces rigid challenges depending on the status of development of the country. Various kind of health policies were applied from past to present day. In the last decades prenatal care was cornerstone but the effectiveness of prenatal care was limited because of its timing. Thus health care professionals emphasize importance of preconception care before prenatal care. In Turkey preconception care had been given by any doctor at the time of 1930s. Then it was given by mother and child health care centers. Nowadays family physicians give this care. The movement to establish family medicine in Turkey started at least 10 years ago.

Every woman of reproductive age who is capable of conceiving is a candidate for preconceptional care, regardless of whether she is planning to become pregnant.

Preconception care is the provision of biomedical, behavioural and social health interventions to women and couples before conception occurs. It is defined as a set of interventions that aim to increase mothers and infants' level of wellness and to avoid hazardous substances before becoming pregnant to reduce morbidity and mortality.

The core components of appropriate preconception care consist of risk assessment, health promotion, clinical and psychosocial interventions. We identified several priority areas, such as FINDS (family violence, infections and immunization, nutrition, depression, and stress) for risk assessment or BBEEFF (breastfeeding, back-to-sleep, exercise, exposures, family planning and folate) for health promotion. Physical examination also is needed to be aware of health care professionals. It should consist weight-height measure, blood pressure measure, breast examination, pelvic examination.

Preconception care prevents the barriers in front of a healthy pregnancy such as unplanned pregnancy, age related risks, family and genetic history problems.

Keywords: primary health care, preconception care, prenatal care.

Primary Ovarian Insufficiency – a case report

Catarina Bica, Nuno Sena De Barros, Andreia Gonçalves, Ana Sofia Rua, Luís Ribeiro
USF Marquês de Marialva, Cantanhede, Portugal

BACKGROUND: Primary hypogonadism in women is defined as ovarian failure accompanied by high serum follicle-stimulating hormone (FSH) concentrations. Premature ovarian failure (POF), now called primary ovarian insufficiency (POI), is a primary hypogonadism in a woman under the age of 40 years with a normal karyotype. POI is characterized by loss of oocytes, lack of folliculogenesis and ovarian estrogen production, and infertility. The presenting symptoms are similar to those of menopause.

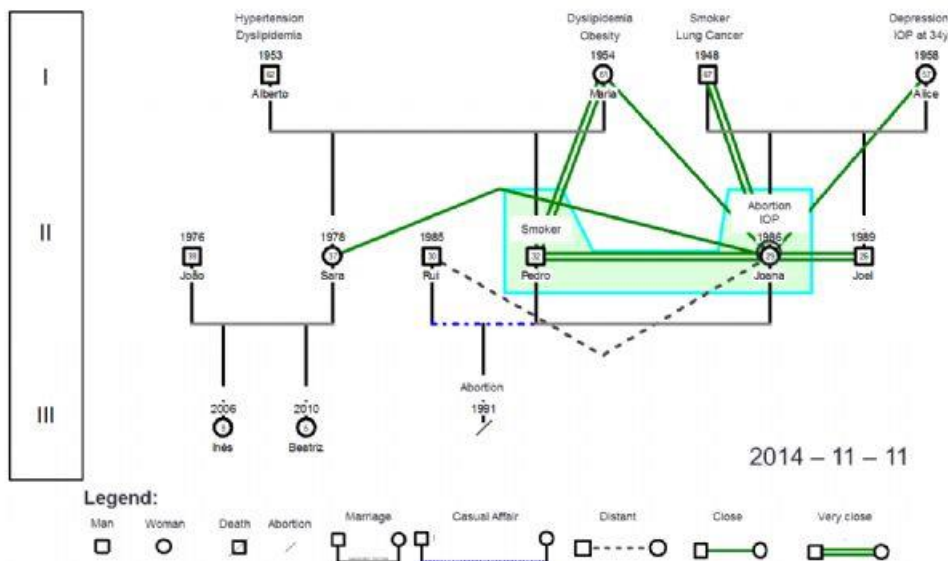

AIM: This case report aims to alert the general practitioners to these symptoms, in order to refer these women as soon as possible to reference fertility centers.

Method & RESULTS: Woman, 28 years old, designer, married, without children. Duvall life cycle fase I. Previously healthy, with menarche at 9 years old, regular cycles 28/5, G1P0: one voluntary abortion at 23 years old. Her mother and her maternal grandmother both had POI at 34 and 38 years old, respectively. She comes to our consultation for the first time complaining of amenorrhea for about six months, symptoms of estrogen deficiency with two years of evolution and failure in becoming pregnant in the last year. We asked for an analytic study and a gynecologic ultrasound. One month later she returns with the results revealing high serum FSH levels (112,0) and low estradiol <5. The anti-müllerian hormone's levels were <0,10. The patient was diagnosed with POI, confirmed in the ultrasound, and was sent to our reference fertility center to further genetic study.

CONCLUSION: There are several known causes of ovarian failure, including chromosomal defects, exposure to radiation, certain drugs and autoimmune disease. The list of mutations that can cause ovarian failure has increased rapidly, as discoveries from the human genome project increase our understanding of the factors involved in ovarian development. Unfortunately, the etiology remains unknown in approximately 75 to 90% of cases.

Keywords: primary ovarian insufficiency, FSH levels, infertility

⁷SEMFYC. Spain

Background and AIM: To determine the physical parameters in pre and postmenopausal women under stress (stress test). Assess the correlation between hormone and lipid levels with the estimated MET (Metabolic Equivalent) functional capacity.

METHOD: Retrospective cross-sectional study. Inclusion criteria: Being female. Outpatient from cardiology consultations or hospitalized had been subjected to an exercise test and blood test, after signing the informed consent, from April to November 2014. Clinical analysis included lipid profile (total cholesterol, LDL, HDL and triglycerides), HbA1C and hormonal (estrogen, progesterone and testosterone). High correlation MET (MET > 8.7) was assessed among: high blood pressure (BPM_{max}), maximum heart rate (HR_{max}), FSH, LH, estrogen (E), progesterone (P), testosterone (T), total cholesterol (C), triglycerides (TG), LDL (L) and HDL (H). Statistical significance $p \leq 0.05$

RESULTS: 130 patients. Age: <50 years: 19.23%; ≥50 years: 69.23%; 15 losses. Overall: MET 7.55 (± 2.06); BPM_{max} mmHg 171.27 (± 24.42); HR_{max} 135.65 bpm (± 24.63); FSH 60.58 IU / L (± 33.33); LH 27.91 IU / L (± 16.44); E 29.78 pg/mL (± 89.43); P 1.19 ng / mL (± 2.12); T 29.13 ng/dL (± 17.48); Tg 113.89 mg/dL (± 64.48); C 205.03 mg / dL (± 43.37); LDL 123.53 mg / dL (± 37.48); HDL 58.8 mg/ dL (± 12.79).

High MET: 26 patients (22.61%). MET 10.26 (± 0.62); BPM_{max} 155.96 mmHg (± 21.17), $p < 0.01$; HR_{max} 157.08 bpm (± 21.49), $p < 0.01$; FSH 29.36 IU/L (± 30.09), $p < 0.05$; LH 22.01 IU/L (± 16.13); E 59.21 pg/mL (± 5404), $p < 0.01$; P 3.11 ng/mL (± 3.89) $p < 0.01$; T 31.45 ng/dL (± 11.38)

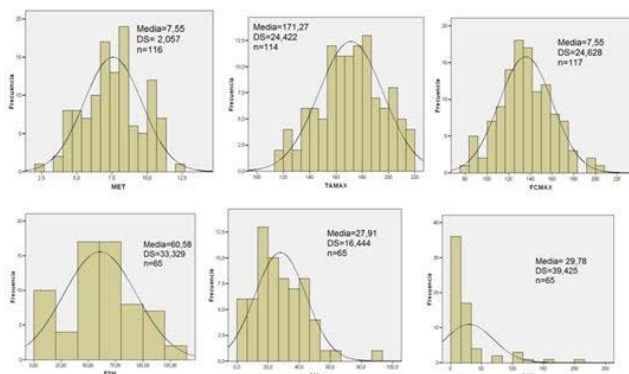

CONCLUSIONS:

Functional capacity is a strong predictor of the morbidity-mortality ratio and survival rate, while MET is an indirect measure thereof. Patients with elevated MET had significantly higher estrogen and progesterone and lower FSH levels. During exercise high MET patients responded with lower systolic BP and higher HR.

Articulation between Primary Health Care and Obstetrics: importance and content of the referral letter

Maria Joao Lobato Cortesao Nobre¹, Marta Renda²

¹USF Gadiana, Castro Marim, Portugal

²USF Lauroe, Loulé, Portugal

Background and AIM:

The good coordination between primary and secondary health care is essential to ensure excellence to all patients. Thus a timely and appropriate referrals, providing the hospital doctor all the necessary information, becomes crucial. During the Obstetrics stage we had the opportunity to observe the consultation requests made by Family Doctors, hearing complaints regarding the lack of information in some letters.

Therefore we decided to do a literature review regarding the referral letters, in order to understand what information needs to be conveyed between the Family Doctor and the hospital doctor.

METHOD:

This review work was based on research in Medline with the search engine Pubmed on February/2015 with the following words: “referral from primary care to secondary care” and “(((referral[MeSH Terms]) AND letter[Title/Abstract]) AND consultant[Title/Abstract]) AND ((primary care[Title/Abstract]) OR general practitioners[Title/Abstract])”. From the articles found, we select the ones written in English or Portuguese, published between January/1990 and February/2015, and excluded the ones related with specific referral to specialties non-obstetric.

We also research on Portuguese Health General Directorate and International Societies of Obstetrics webpages for documents or guidelines related with obstetrics referral.

RESULTS:

Referral and reply letters are the sole means of communication between doctors most of the time and breakdown in communication could lead to poor continuity of care, delayed diagnoses, polypharmacy, increased litigation risk and unnecessary testing.

Studies reported that specialists are dissatisfied with referral letter’s quality and content.

In the field of maternal-fetal medicine, incomplete referral letters that fail to comprehensively identify pregnancy risk factors can have significant implications for pregnancy management and delivery planning.

CONCLUSIONS:

The routine use of patient questionnaires or referral letter templates, the development of local referral

guidelines, and regular clinician education are some recommendations to improve the referral communication and save time for both general practitioners and specialists.

⁵Department of Internal Medicine, Gulhane Military Medical Faculty, Ankara, Turkey

AIM: Generalized anxiety disorder (GAD) seems to affect population in different levels. Gender difference is one of the factors for anxiety severity. Prevalence of GAD is 2 fold higher in females. In this research, we aimed to identify the Beck Anxiety Scale Score (BASS) differences according to gender.

METHOD: A total of 73 patients enrolled in this study. BASS levels of female and male patients were compared. SPSS 20 for Mac used to analyze the data. Mann-Whitney U test was used to compare the groups.

RESULTS: There were 61 (83.6%) female and 12 (16.4%) male. The mean BASS in female and male patients were 26.18 ± 10.17 (7-57) and 18.83 ± 11.53 (4-49), respectively ($p=0.007$).

CONCLUSIONS: Female patients were higher BASS than males.

P-0742**Menopause And Thiol/Disulphide Homeostasis**

Basri Furkan Dağcıoğlu¹, Tuncer Kılıç¹, Ahmet Keskin¹, Aylin Baydar Artantaş², İrep Karataş Eray², Yusuf Üstü¹, Mehmet Uğurlu¹

¹Department of Family Medicine, Yıldırım Beyazıt University, Faculty of Medicine, Ankara, Turkey

²Family Medicine Clinic, Atatürk Training And Research Hospital, Ankara, Turkey

Background/AIMS: Thiol/ disulphide homeostasis has a critical role on cellular events like antioxidant protection and apoptosis. There is also a growing body of evidence demonstrating that an abnormal thiol disulphide homeostasis state is involved in the pathogenesis of a variety of diseases. It is shown in many studies that the depletion of estrogen in postmenopausal period could cause oxidative stress. We aimed to investigate the relationship between menopause and thiol/disulphide homeostasis which is a new indicator for the oxidative stress.

METHODS: Thiol / disulphide homeostasis parameters were studied in the blood samples of 25 postmenopausal women and 29 women in reproductive period in the control group, who were 18 years or over and admitted to outpatient clinic of our hospital between December 2014 and March 2015. Subjects were selected from 574 patients according to exclusion criteria including history of chronic disease, smoking, alcohol consumption and malignancy. Venous blood samples were obtained from patients and centrifuged for 15 minutes at 3600 rpm to obtain plasma. After that, native thiol, disulphide, total thiol, index 1 (disulphide/native thiol), index 2 (disulphide/total thiol) and index 3 (native thiol/total thiol) levels were measured. Statistical analyzes were performed on 54 patients. All statistical analyzes were performed with IBM SPSS Statistics (V.16) computer program. $P < 0,05$ was accepted as statistically significant.

RESULTS: Native thiol and total thiol levels of postmenopausal women were significantly lower than the control group [($p < 0,001$; $Z: -4,45$) and ($p < 0,001$; $Z: -3,94$) respectively], whereas index 1 ($p: 0,006$; $Z: -2,76$) and index 2 ($p: 0,006$; $Z: -2,23$) levels were witnessed higher. (Table 1)

CONCLUSION: These findings are the first results of our continuing study and we aim to finish the process with higher amounts of patient data in order to publish the final results. Further studies may reveal the clinical importance of dynamic thiol/disulphide homeostasis on many conditions like postmenopausal period.

BACKGROUND: The aim of our study is assessing home care services concerning women's health by means of gynaecologic and urogynecologic problems such as urinary incontinence and genital cancers and pointing out possible deficits to support the reorganization of the team work in this area. **METHODS:** A questionnaire is applied by face to face interviews during consecutive home visits by the caregivers to 100 women who were receiving home care services. **RESULTS:** The mean age of patients was 67, 95±12, 93 (22-84). Their primary diseases registered by home care services were 33% cerebrovascular accident, 16% Alzheimer-dementia, 8% various orthopedic interventions, 6% cardiovascular disease. Concomitant diseases were mainly hypertension (57%), diabetes mellitus (46%), osteoporosis (18%), chronic obstructive pulmonary disease (15%) and besides 63% neurological deficits, 17% orthopedic problems and 5% malignancy were registered; Only 46 out of 100 patients could be questioned directly without the help of family members and 35 of these 46 patients (76%) had gynecologic or urogynecologic complaints. **CONCLUSION:** A significant proportion of old women suffer from serious urogynecologic health problems, which necessitates more efforts for care of them.

Sacral Insufficiency Fracture in a Pregnant Women

Hatice Guler, Yasemin Alagoz, Merve Erdogan
Konya Education and Research Hospital

PURPOSE

Insufficiency fractures are caused as a result of exposure of the bone whose elasticity decreased to normal or physiological stress. It is frequently seen in the elderly women having osteoporosis. But, it can be seen rarely in pregnancy or postpartum period. Sacral insufficiency fractures have no specific symptoms and also its radiography findings are frequently normal. In this paper, the clinical and radiologic findings of sacral insufficiency fracture are discussed.

CASE REPORT

A 32-years-old female patient applied to our hospital with complaints of low back pain started in her pregnancy and increased after the delivery. Low back pain were painful and restricted particularly in the right side in the physical examination. Laboratory and radiography findings were normal. MRI examination was performed to determine the reason of pain. Linear hypointense fracture line was seen on T1 weighted series in the sacrum, and edematous signal changes was also seen adjacent to the fracture line as hyperintense areas on fat saturated T2-weighted images.

DISCUSSION

Sacrum insufficiency fractures are seen particularly in elderly women who are above 60 years old and have osteoporosis. It is rarely seen in pregnancy and postpartum period. Vaginal delivery, overweight baby, forceps use, heparin use, gaining over-weight, reduction in maternal calcium intake and vitamin D deficiency increase the risk of sacral insufficiency fracture in postpartum period. The most frequent symptom is back and low back pain. Treatment tends to be conservative. The first step is pain control. Bed rest, acetaminophen, analgesic and anti-inflammatory agents and physical therapy modalities may be used until the pain is removed. Sacrum insufficiency fracture should be certainly considered in differential diagnosis although it is an atypical case in evaluation of low back and hip pains in pregnancy and postpartum periods.

Keywords: pregnancy, sacral, fracture, insufficiency

Figure 1

Linear hypointense fracture line was seen on T1 weighted series starting from the sacrum ala extending to neural foramens localization in right sacrum (Figure 1a). Edematous signal changes (bone marrow edema) was also seen adjacent to the fracture line as hyperintense areas on fat saturated T2-weighted series (Figure 1b)

Thinking hypothyroidism in a patient with anemia of chronic disease and hyperlipidemia: Case report

AIM: The patient with anemia of chronic disease and hyperlipidemia presented management of hypothyroidism considering the patient's symptoms and signs.

METHODS: A review of the literature was made. **RESULTS:** A 41 year woman came with complaint of fatigue, overweight (BMI:39), constipation and depression. Detailed history of the patient was taken. There were early menopause (36 year). In family history, her daughter had type 1 diabetes mellitus and hypothyroidism. Physical examination of the patient was apathic view, alopecia, dry skin, fragile nails, thyroid palpable, trace amounts of bilateral pretibial edema and obesity. Blood investigations, detected hypochromic microcytic anemia, hypertriglyceridemia and hypercholesterolemia (see Table I). Differential diagnosis, It was considered the infection, vitamin deficiency, hypothyroidism, anemia, and may be connected with obesity. Patient's signs and symptoms were evaluated for hypothyroidism (see Table I). In these parameters, we thought that etiology of anemia of chronic disease and hyperlipidemia was detected in hypothyroidism. Thyroid function tests, thyroid peroxidase antibody and thyroid ultrasonography were made. We determined Hashimoto's thyroiditis. Levothyroxine 50 mg / day and 20 mg fluoxetine (for depressive mode) treatment was started. 6 weeks after the control laboratory tests showed (see Table I). Levothyroxine dose of 100 mcg / day was set. Patients complaints decreased and she is follow-up.

CONCLUSION: Anemia of chronic disease and hyperlipidemia associated with cases should be detailed history. Hypothyroidism symptoms and signs must be identified. Hypothyroidism is a common cause of anemia of chronic disease and hyperlipidemia.

Keywords: hypothyroidism, hyperlipidemia, anemia of chronic disease

Prevalence of Obesity Among Lebanese Women

Yasser Yaghi¹, Shadene Yaghi², Zahra Saad², Ahmad Hesso¹

¹Beirut Arab University-Lebanon

²American University of Beirut-Lebanon

INTRODUCTION:

Overweight has become an epidemic problem worldwide and is the most rapidly growing form of malnutrition in the developed world. It is responsible for the increasing prevalence of serious health outcomes and is a leading preventable cause of death.

The aim of this study was to describe prevalence of overweight among Lebanese women over a period of 4 years and in lower socio-economic groups living in South Lebanon, an under privileged region.

Subjects and METHODS:

Data was collected from 825 ambulatory Lebanese women attending out-patient clinics in one Hospital between 2010 and 2013. All subjects were submitted to Osteodensitometry unit for routine check-up for osteoporosis. Indicators recorded were: age, height, weight, gender, Body Mass Index (BMI), Total body Fat (TBF), Gynoid fat and Android Fat. Data was analyzed using the statistical package for social sciences (SPSS).

Overweight was defined as BMI between 24.9 and 29.9kg/sqm. TBF was considered above average when it was 40% for women 41 to 60 years.

RESULTS:

The mean age of women studied was 60.92 years (SD 10.93 years). The mean BMI was 30.15kg/sqm (SD 5.22kg/sqm) while the mean TBF was 45.99% (SD 6.30%). The mean android fat was 49.76%, while the mean gynoid fat was 50.24%

CONCLUSION:

The findings of this study highlight prevalence of overweight among Lebanese women which appeared to be stable over the study period. The Total Body % Fat was above average. These findings should alert to the importance of formulating strategies to curb the progression of overweight in Lebanon. And The alarming increase in obesity prevalence raise questions about its implications for health and disease burden in Lebanon.

Limitations:

The majority of adults studied belong to a low socio-economic groups.

Ocular complication following zoledronic acid infusion

Lana El Osta¹, Badi El Osta²

¹Department of Public Health, School of Medicine, Saint-Joseph University, Beirut, Lebanon

²Georgia Regents University Cancer Center, Augusta, GA, USA

BACKGROUND AND AIM: Short-term clinical trials and subsequent extensions are not powered to detect rare adverse events such as ocular complications related to bisphosphonates. Given the large and growing number of patients receiving these medications, it is likely that physicians may encounter some patients with these side effects.

The aim of this case presentation is to recognize an inflammatory ocular complication in a patient on bisphosphonate, and to inform the patient on the eventuality of this complication before initiating the medication.

METHODS: We present a case of a recurrent acute blepharitis after the infusion of zoledronic acid.

RESULTS: A 62-year-old osteoporotic female presented for management of a recurrent swollen left eye since the introduction of the zoledronic acid 3 years earlier. It was initially painless, and appeared 48 hours after each infusion, with spontaneous and complete resolution 5 days later. Lately, the recurrent swollen eye lasted longer and was more expanded. It was associated to burning, dryness, and photophobia with no diplopia. Ophthalmologic exam including a slit-lamp showed edema and redness of the left upper lid, with no exophthalmos, and no elevated intraocular pressure. The vision was unaffected. A swabbing of the eyelid secretions was negative for bacteria and fungi. A topical treatment was administered, including steroid eye drops and ointment as well as artificial tears, and lid hygiene recommended. Two weeks later, the woman was completely recovered.

CONCLUSION: Bisphosphonates are widely used for the treatment of osteoporosis. Healthcare care providers should be aware of ocular complications related to these medications and must inform their patients, so that they can seek immediate assessment.

Keywords: Bisphosphonates, Osteoporosis, Recurrent blepharitis, Ocular complications

Unilateral acute blepharitis in a female patient receiving zoledronic acid for postmenopausal osteoporosis

Imputability of the zoledronic acid

To assess the imputability of the zoledronate, the WHO Causality Guide of Suspected Adverse Reactions was used. This case of periorbital inflammation may be classified as “certain” adverse effect of the zoledronic acid because it satisfied the following criteria:

- Plausible time relationship to the bisphosphonate intake
- Plausible response to the rechallenge and dechallenge
- Absence of concurrent disease or other drugs predisposing to the complication. No new treatments have recently been initiated. There were no indicators of any other diagnosis with the patient: no previous ocular diseases, no clinical signs of seborrheic dermatitis or rosacea, no history of new allergen introduction, no evidence of infection,...

Preferences of Pregnant Women in the Central District and Surrounding Areas of an Eastern Province in Turkey for Cesarean or Vaginal Birth, and Associated Factors

Edibe Pirincci¹, Berrak Yildirim Aksakal², Ibrahim Halil Akkus²

¹Firat University School of Medicine. Department of Public Health, Elazig/TURKEY

²Public Health Institution, Elazig/TURKEY

BACKGROUND & AIM: The aim of the study is to identify the rate at which pregnant women in the central district and surrounding areas of an eastern province in Turkey prefer cesarean versus vaginal birth and to reveal the associated factors.

METHOD: The population of the study comprised pregnant women who were registered for one of the 173 family practice centers located in the center and surrounding districts of Elazig, Turkey, and who visited one of such family practice centers for a routine pregnancy check up during the period of time that coincided with the study. The survey was administered to the first four of these visiting pregnant women. The sample contained 628 pregnant women. **RESULTS:** The mean age of the pregnant women was 28.52±5.43 years. For the question as to their preferred mode of birth in the absence of any medical indication for cesarean birth and given the opportunity to choose either mode of birth, the responses were distributed as follows: cesarean birth (17.8%). A significant increase was observed in the preference for cesarean birth as educational status and income level increased ($p<0.05$). Among the pregnant women who had already had a cesarean birth, a significant proportion stated that they would prefer that mode again ($p<0.01$). Similarly, those with a previous experience of miscarriage chose to have a cesarean birth for their current pregnancy ($p<0.05$). The number-one reason for the preference of vaginal birth was viewing it as "healthier and better," followed by "early recovery." However, the factors in the preference for cesarean birth were as follows (in descending order): "fear of vaginal birth," "the wish to avoid pain."

CONCLUSION: Pregnant women have high levels of preference for cesarean birth. It is recommended that information activities should be organized so as to allay their fears.

"{"How dressing styles of women effects Vitamin D levels?"}"

Neslihan Övet, Gülsen Ceyhan Peker, Ayşe Selda Tekiner

Department of Family Medicine, Ankara University School of Medicine, Ankara, Turkey

“Background and AIM: The aim of this research was to investigate the prevalence of Vitamin D (Vit D) deficiency and relationship of this with dressing styles of women.

METHODS: This cross sectional study was conducted at Ankara University School of Medicine Outpatient clinics of Family Medicine and Physical Therapy and Rehabilitation between May- October 2012 and at the same months in 2013.

312 premenopausal women whose Vit D values were analysed before for their complaints were interviewed face to face during their control visit. Participants were divided into two groups according to their dressing styles (Veiled or modern clothing style).

RESULTS: Vit D deficiency among all participants were 66%. Severe Vit D deficiency was 23%, only 9.3% of the whole group had normal levels. When we compared normal Vit D levels of veiled women to women with modern clothing, only 3.7% of the first group had normal levels whereas this was 13% in the second group ($p<0.05$).

Severe Vit D deficiency (44.4%) and inadequacy (43%) were more prominent in veiled women whereas these levels were 6.8% and 43.5% respectively in women of modern clothing. This situation may result from restricted sun exposure and permanently being in closed areas like houses. CONCLUSION: The community should be informed about the importance of sun exposure and Vit D.” ”

The Frequency of Smoking Exposure Among Pregnant Women

Yusuf Akyüz¹, Oktay Sari¹, Mustafa Dinç², Ümit Aydoğan¹

¹Gulhane Military Medical Academy, School of Medicine, Department of Family Medicine, Ankara, Turkey

²Gulhane Military Medical Academy, School of Medicine, Department of Endocrinology and Metabolism, Ankara, Turkey

Introduction

Smoking and exposure to cigarette smoke may cause some problems both for mother and her fetus during pregnancy. Detailed questioning about smoking habits of pregnant and counselling have an important place in the first step in the course of observing. In our study, we evaluated smoking and passive smoking status of pregnant women.

Method

The pregnant were included in our study admitted to our outpatient clinic. A questionnaire was filled by pregnant including the demographic characteristics and smoking habits of the pregnant, and characteristics of smokers where living in a household with them and analysis was performed in accordance with this data.

Findings

The average age of the 188 women who recruited the study was 29.37 ± 6.02 years (18-42 years). There were 17 pregnant in the first trimester (9%), 28 in the second trimester (14.9%) and 143 in the third trimester (76.1%). When asked about the smoking habits of pregnant, it was learned that 168 women did not smoke (89.4%). 136 of them (%72,3) had never smoked so far, and 32 (%17) gave up smoking because of pregnancy. 20 (%10,6) smoked sometimes during pregnancy. 12 smoker (%60) had high school and upper graduation. When asked to pregnant women whether anyone to smoke or not to smoke in their homes, although 104 pregnant (%55,3) replied no, 84 women (%44,7) replied yes. When they were asked about who smoked in the house, 54 of them (%64) consisted of their spouses.

Conclusion

It is understood that smoking is a kind of illness and smokers must be treated. Pregnancy is an important period of life. Smoking is a preventable risk factor, and the counseling training and the pregnancy monitoring performed at regular intervals are important for maintaining a healthy pregnancy, and the role of family physicians is significantly great in here.

Relationship between vaginal infection and anemia during pregnancy

Daiva Dvareckyte, Egle Zekonyte, Kazys Simanuskas

Vilnius University, Faculty Of Medicine: Clinic of internal diseases, family medicine and oncology, Family medicine center, Vilnius University, Vilnius, Lithuania

Background and AIM: Vaginal infection is the most common reason for women applying to the family doctor or obstetrician-gynecologist, accounting for about 60-70 percent all gynecological pathology. One of the risk factors potentially having a connection with vaginal infection is anemia, which is still one of the most common public health issues, in both developing and developed countries. Anemia during pregnancy not only has a negative effect on both mother and fetus and often leads to unfavorable pregnancy, childbirth outcomes, but also weakens the immunity of pregnant women, which leads to changes in the vaginal ecosystem and the occurrence of vaginal infections. The aim of the study was to find links between vaginal infections and anemia during pregnancies in the Family medical center of Vilnius University Hospital Santariskiu clinic in Lithuania.

METHODS: A total of 498 medical records of pregnant women were included as a study subject from year 2011 to 2014. The main hematological indicators (Hgb, Hct, MCV, MCHC) and vaginal smear results (leukocytes, agents) during pregnancy were assessed. The data was processed and analyzed using Microsoft Office Excel 2007 and the

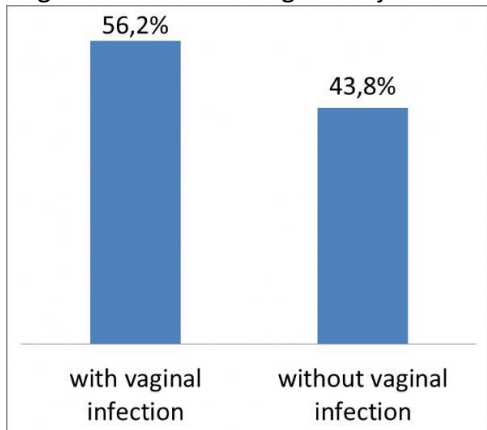

Statistical Package for Social Science version for Windows 17.0. The statistical difference was considered significant if the P value was below 0.05.

RESULTS: The analysis showed that the prevalence of prenatal vaginal infection morbidity among all subjects, was 56.2% (n=280) and anemia - 38% (n=188). Anemia was diagnosed in 39% (n=109) of patients with vaginal infection. There was no significant difference between anemia and vaginal infection during pregnancy.

CONCLUSIONS: The study showed that anemia among pregnant women has a connection as a risk factor to vaginal infection in Santariskiu clinic Family medical center.

Analysis of the treatment for vaginal infection during pregnancy

Daiva Dvareckyte, Egle Zekonyte, Kazys Simanauskas

Vilnius University, Faculty Of Medicine: Clinic of internal diseases, family medicine and oncology, Family medicine center, Vilnius University, Vilnius, Lithuania

Background and AIM: Vaginal infection is the most common reason for both pregnant and not pregnant women applying to the family doctor or obstetrician-gynecologist. The aim of the study was to carry out a vaginal infection treatment analysis during pregnancy in the Family medical center of Vilnius University Hospital Santariskiu clinic in Lithuania.

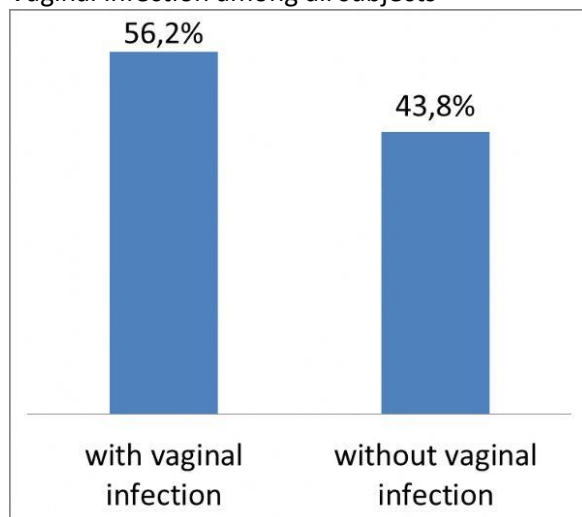

METHODS: A total of 498 medical records of pregnant women were included as a study subject from year 2011 to 2014. The main symptoms (vaginal irritation, painful intercourse, vaginal discharge, bleeding after intercourse), vaginal smear results (leukocytes, agents) and the treatment during pregnancy were assessed. The data was processed and analyzed using Microsoft Office Excel 2007 and the Statistical Package for Social Science version for Windows 17.0. The statistical difference was considered significant if the P value was below 0.05.

RESULTS: The analysis showed that prevalence of prenatal vaginal infections morbidity among all subjects was 56.2%. 70% of them were assigned treatment, $p < 0.05$. Symptoms occurred among 36% of pregnant women with vaginal infection, $p < 0.05$. Whereas vaginal smear results found 39% Gram rods negative, 31% Gram cocci positive, 28% candida, and 1% Gram rods positive, indicator cells, gonococci and trichomonas each, $p > 0.05$. Leukocytes covering the field of vision occur in 44% of vaginal smears, > 20 cells/field in 25%, 5-20 cells/field in 25%, 0-5 cells/field in 39%, $p < 0.05$. Recurrence after treatment equals 20%, $p < 0.05$. The fixed combination of Nifuratel and Nystatin is the most frequently (37%) selected treatment.

CONCLUSIONS: According to our study the treatment for a vaginal infection among pregnant woman is based on the symptoms and the results of a vaginal smear. The recurrence of vaginal infection after treatment is 20%. The fixed combination of Nifuratel and Nystatin is the most frequently selected cure.

Risk factors of vaginitis analysis in pregnant women

Egle Zekonyte, Daiva Dvareckyte, Kazys Simanauskas

Vilnius University, Faculty Of Medicine: Clinic of internal diseases, family medicine and oncology, Family medicine center, Vilnius University, Vilnius, Lithuania

Background and AIM: Vaginitis - one of the reasons why women go to see an obstetrician-gynecologist and pregnancy is one of the most important risk factors to get this infection. During pregnancy vaginitis is associated with a great number of gynecologic and obstetric complications, such as preterm birth, postpartum endometritis, inflammatory pelvic disease or low birth weight. The aim of the study was to analyse prevalence of risk factors among pregnant women in the Family medical center of Vilnius University Hospital Santariskiu clinic in Lithuania.

METHODS: There was reviewed 498 medical records of pregnant women from 2011 to 2014. Risk factors such as older age (>35 years), bigger weight (BMI >24,9), urinary tract infection, chronic infection (carrying B group beta-haemolytic streptococcus infection, trichomoniasis and CMV infection), arterial hypertension, diabetes mellitus and multiple pregnancy were assessed during the study. The data was processed and analyzed using "Microsoft Office Excel 2007" and the "Statistical Package for Social Science version for Windows 17.0". The statistical difference was considered significant if the "P" value was below 0.05.

RESULTS: The analysis showed that 90,4% pregnant women with vaginitis had at least one risk factor. The most common risk factor was urinary tract infection 37,5%. 15,7% women had a chronic infection, 12,9% – bigger weight and 15,4% pregnant women were older age. Also there were 1,8% women with diabetes mellitus, 2,1% women with arterial hypertension and 1,1% women with multiple pregnancy. Significant statistical difference was found between urinary tract infection and vaginitis " $p < 0.05$ ".

CONCLUSIONS: In this study the most common risk factors were urinary tract infection, chronic infection and older age. There was a significant difference between urinary tract infection and vaginitis.

Relationship between vaginitis and number of deliveries in pregnant women

Egle Zekonyte, Daiva Dvareckyte, Kazys Simanuskas

Vilnius University, Faculty Of Medicine: Clinic of internal diseases, family medicine and oncology, Family medicine center, Vilnius University, Vilnius, Lithuania

Background and AIM: pregnancy is one of the most important risk factors of vaginitis. Pregnant women and women who often get vaginitis should pay more attention at their hygiene. We think that women, who are pregnant not for the first time, know better how to prevent vaginitis than women who are pregnant for the first time. The aim of the study was to see if women, who are pregnant for the first time, get vaginitis more often than women, who are pregnant not for the first time in the Family medical center of Vilnius University Hospital Santariskiu clinic in Lithuania.

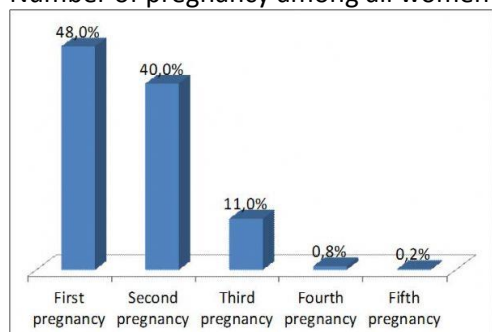

METHODS: We reviewed 498 medical records of pregnant women from 2011 to 2014. The data was processed and analyzed using "Microsoft Office Excel 2007" and the "Statistical Package for Social Science version for Windows 17.0". The statistical difference was considered significant if the "P" value was below 0.05.

RESULTS: 48% of all pregnant women were pregnant for the first time. There was more women with vaginitis, who was pregnant for the first time, than women who had 1 or more deliveries. Between women who had no deliveries or had 1 delivery, a bigger part of them had vaginitis (57,7% and 57,3%). Between women who had 2 and more deliveries, a smaller part had vaginitis (46,7%). We didn't find a statistical significant difference between deliveries number and vaginitis " $p > 0,05$ ".

CONCLUSIONS: there was more women with vaginitis among women who had no or 1 delivery, than among women who had 2 or more deliveries.

⁴Department of Obstetrics and Gynecology, Muğla Sıtkı Koçman University Medical Faculty, Muğla, Turkey

⁵Department of Forensic Medicine, Sıtkı Koçman University Medical Faculty, Muğla, Turkey

Background and AIM: Violence against women (VAW) is a preventable public health problem. VAW is a very complex social problem rather than a disease and knowledge and skill of healthcare personnel in approaching towards women exposed to violence is an important issue. The aim of this study was to investigate sociodemographic characteristics, smoking, alcohol and substance use, place and perpetrator of the violence against women.

METHOD: Data of this study derived from the information gathered in the questionnaire forms "Evaluation of the Violence Against Women" which assessed 142 women who consulted to the Emergency Service Emergency Service of Training and Research Hospital of Mugla Sitki Kocman University because of acts of violence committed between January 2013 and December 2014. The questionnaire form contains items about sociodemographic data and those questioning pregnancy status of the woman, cigarette, alcohol and substance use, event site and perpetrator of the violence, use of alcohol or substance by the perpetrator, type and severity of the coercive acts, children experienced or witnessed violence.

RESULTS: A significant correlation was detected between level of education and increase in the severity of violent acts. Perpetrators with primary and secondary school education had exerted more aggressive violent behaviours ($p=0.039$). A positive correlation was detected between referral to violence prevention and monitoring center, fear from going home ($p=0.014$) and increase in the severity of violence ($p=0.000$).

CONCLUSIONS: Within the last two years only 142 women consulted to emergency services which is thought to be the visible tip of the iceberg. As conceivably helpful measures, increasing the level of women's educational level and female employment, development of educational programs on social gender and equality of woman and man beginning from primary school and prevention of making news and description of violent acts in written and visual media should be promoted.

The importance of regular use of oral contraceptives

Funda Ekimci Deniz, Rahşan Bulut, Ayşe Semra Demir Akça, Nejat Demircan
Department of Family Medicine, Faculty of Medicine, Bulent Ecevit University, Zonguldak, Turkey

Oral contraceptives, one of the family planning methods, are frequently used both in our country and in the world. When they are used in appropriate person with accordance, this method has very high retention rate. However, irregular use of the pill and change of drug taken hours in the day reduces the retention rate significantly and formation pregnancy rates can be up to 15%. For this reason, it is important to inform people who use oral contraceptives and follow the person's compliance to treatment. This case is presented for emphasizing the importance of regular use of oral contraceptives and inform people who use oral contraceptives to protect person and baby during pregnancy.

A 26-year-old female patient was admitted to our university pregnant clinic because of pregnancy and drug use. It was learned in interview with patient that she used therapeutic combined oral contraceptive pills because of polycystic ovary syndrome but not regularly and continuously. Over 2 month delay of the period, patient made home tests by suspecting pregnancy. The patient whose test results came positive was admitted to the gynecology and obstetrics specialist on off-center. As a result of ultrasound done in the center, 11 weeks of pregnancy has been identified. Because oral contraceptives pregnancy category was X, the patient was discussed in Obstetrics and Gynecology council. The council suggested continuing period of pregnancy and close monitoring the patient who wanted continuing of pregnancy. In line with the recommendation of the Council, monitoring

the patient is continuing.

Irregular and improper use significantly reduces the retention rate of oral contraceptives. Therefore, doctors should make sure that enough information about this topic is given to patient who is advised oral contraceptives. Some proposals like pill box and applications on smartphones in order to take drugs regularly can be made.

Fertile woman deaths due to dengue fever during 2013 in Goiânia

Gustavo Aguilar Alvarenga Amorim¹, Lara Louise Guimarães Silveira¹, Ana Luisa Franco Moura¹, David Carvalho Rezende¹, Wallace Pinheiro Rodrigues¹, Lorena De Almeida Ribeiro Prudente¹, Vinicius Bernardes Mendonça Damasceno¹, Natália Carasek Matos Cascudo¹, Camila Garcia De Souza², Ayssa Teles Abrão Trad³

¹Universidade Federal de Goiás, Goiânia, Brazil

²Pontifícia Universidade Católica de Goiás, Goiânia, Brazil

³Pontifícia Universidade Católica de São Paulo, Sorocaba, Brazil

Goiânia, one of the main cities in middle-west Brazil, is well-known by the health professionals as an endemic area for dengue fever. The Public Health Ministry hopes to update all the doctors to provide them good ways for conducting their patients, although this is not enough, so there still are deaths.

The aim of this study was to identify the number of women in fertile age (10-49 years-old) dead during 2013 that has as causa mortis dengue fever.

This is a research realized at the health information division of the Goiânia's Municipal Health Secretary Epidemiology Department. The database was the obit declaration from 2013 of the fertile human living in Goiânia combine with the DATASUS. The variables are age, race, civil status, and escolar status.

As a result we found 6 deaths as dengue fever consequence, its 1,27% of the 471 documented deaths during the period. 16,66% were during January; 33,34% in February; 16,66% in March, and 33,34% during December. All them had at least graduated at the middle school, 33,33% of them are in their twenties, 33,33% in their thirties and the rest in their forties.

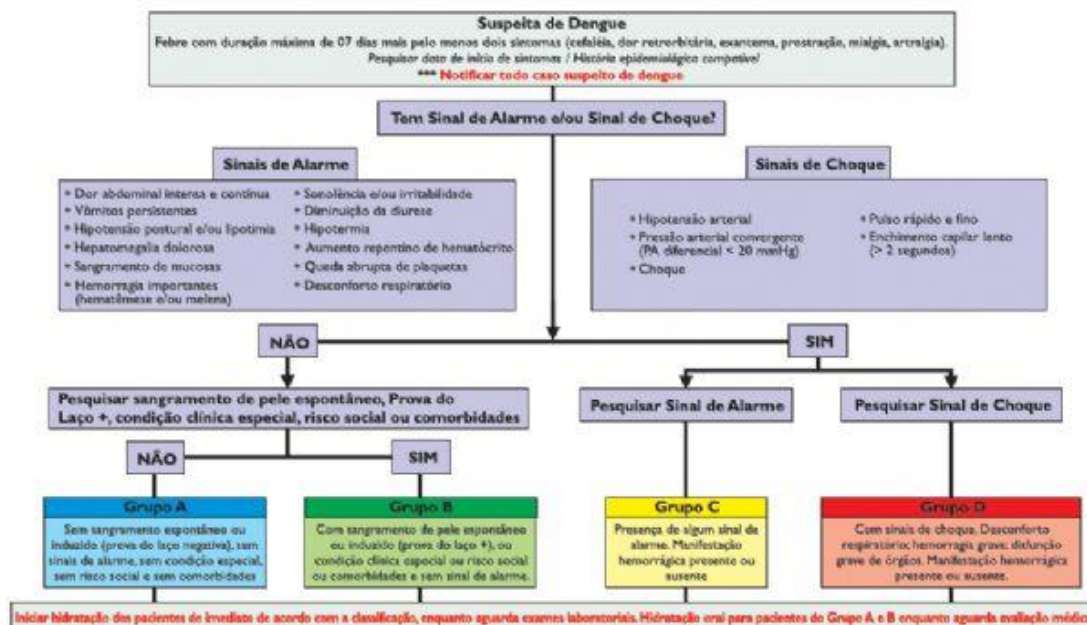

In fact, 6 deaths do not represent a major causa mortis in the city during the summer – epidemic period – even with the well structured clinical management stipulated by constantly re-evaluating the patient and classifying him in a risk group that will determine how it was supposed be conducted. With this in mind, it is possible to conclude that these deaths could really be avoided not only with a more careful management but also with better prevention of the disease.

Urinary incontinence in women older than 40 years

Ebubekir Demireloğlu, Davut Karakurt, Melek Cihanbeylerden, Didem Sunay

Department of Family Medicine, Kecioren Training and Research Hospital, Ankara, Turkey

AIM: Urinary incontinence (UI) is a problem that creates both physical and psychological nuisance to a woman. The aim of this study to assess UI prevalence, medical advice seeking of women and related factors.

METHODS: Women over 40 years old attended to family medicine clinic between January-February 2015 were included in this cross-sectional study. Questionnaire for socio demographic, clinic characteristics, ICIQ incontinence form for UI were used.

RESULTS: A total of 148 women accepted to include into the study, mean age was 54.3±11.1 years, 63.5% of them were in menopause. UI prevalence was 28.4% (15% urge, 12.5% stress, 72.5 mixed), 50% did not consult a physician, among these women 25% thought it was normal, 47.6% of them who got advice were consulted a gynecologist, 28.6% a family physician. Mean ICIQ score was 11.4 out of 12. The mean impact score of UI symptoms on daily life was 6.8 out of 10.

CONCLUSION: It is important to assess and treat UI by family physicians because of its high prevalence and high psychosocial effects.

Analysis of the informal caregivers burden of dependent persons

Ana Duarte¹, Ana Rodríguez¹, Eva Míguez², Manuel Ángel Barbosa¹, Eduardo Díaz¹, Ana Clavería¹

¹Galicia's National Health, Vigo, Spain

²Department of Economy, Vigo University, Spain

Background&AIM: Whereas caregiving has been shown to improve patient outcomes, the consequence of caregiving for caregivers themselves remains debated.

To quantify the impact of caregivers' burden on their health. To analyze the influence of their risk factors, arising from themselves and from their dependents.

METHOD: Descriptive observational study in primary care setting in Spain. Caregivers who provide care to a dependent adult population were included (N = 97). It was collected socioeconomic information, different health status measures of both the keepers and the dependent, and the load of the caregiver through Zarit scale short version (outcome variable) through a personal interview. Descriptive analysis and logistic regression was performed, with Stata 12 software.

RESULTS: The average burden was 19.4, and 61.9% of caregivers had severe overload (Zarit ≥ 17). The burden was correlated significantly ($p < 0,05$) with the degree of consanguinity, the health of the caregiver, dependent's aggressiveness and if they had psychiatric illness.

CONCLUSIONS: The informal carers of dependent persons present a high level of burden, influenced by their own health and by dependent person characteristics. This overload, the social factors that surround the caregivers and their dependent patient, raises addressing the needs of both together. Understanding the caregiver risk factors will provide insights into how intervention programs can be best tailored to them. The multiprofessional team (GPs, nurses, social workers) must look after the patient problems as much as those of his/her carer, avoiding the physical and psychological health deterioration of the latter.

Pregnancy After Tubal Ligation: A Case Report

Aynur Yalçıntaş¹, Püren Cura Ecevit², Özlem Öztaş³, Burcu Kayhan Tetik⁴

¹Konya Karatay No:9 Family Health Center, Konya, Turkey

²Konya Meram No:25 Family Health Center, Konya, Turkey

³Ankara EÜAŞ Health Department, Ministry of Energy, Ankara, Turkey

⁴Inonu University Medical Faculty, Department of Family Medicine, Malatya, Turkey

INTRODUCTION:

Family planning provides individuals to have children when they wished to have and in a number they are able to take care of. According to the data from Turkey Demographic and Health Survey (TDHS 2013), 74% of married women of childbearing age have been using a contraceptive method, in Turkey. Again, in the same study it has been reported that 47.5% of them have preferred to use modern methods, whereas 9.4% of this rate have undergone tubal ligation.

CASE:

Thirty-three-year-old woman admitted to our Family Health Center with complaints of nausea, fatigue and menstruation was 10 days delayed. The patient stated that she underwent tubal ligation 7 years ago. No pathological findings were detected. The patient was convinced to make pregnancy test done, and the results were Beta HCG > 150,000 mIU / ml. The patient was informed that she was pregnant according to the laboratory data, however an ultrasound examination was required to confirm the laboratory results. Then she was referred to gynecology and obstetrics polyclinic. The ultrasound examination revealed that she was 5 weeks pregnant and the patient was directed to our family medicine center to be followed up. The patient delivered a 3500 grams, healthy baby boy at the end of 39 weeks 2 days of pregnancy by cesarean (C / S).

CONCLUSION:

There is a way of patient interview which is peculiar to family medicine physicians. To gain patients' confidence through repeated interviews is very important to convince the patients. As seen in our case, in patients in the reproductive age, the probability of pregnancy should be considered even if the patient has been protected by a method such as tubal ligation in cases of delays of menstruation, and necessary test should be requested.

INTRODUCTION: A reduction occurs in levels of some minerals and vitamins due to physiological adaptation during pregnancy, and this situation causes anemia in pregnancy. In this study the effect of ferritin, vitamin B12 and folic acid levels on the outcomes of the pregnancy were evaluated.

MATERIALS-METHODS: 72 pregnant women with third trimester of pregnancy were included in the study. Vitamin and mineral analyzes of the patients were done. Whether or not iron and vitamin supplements received during pregnancy were asked, and mode of delivery and the history of postpartum problems occurred in infants were questioned.

RESULTS: Anemia was detected in 29 percent of pregnant women in the study. An increase was detected in the incidence of anemia among women with 2 or more children while the rate of anemia in primipar women was low. An increase was seen in the incidence of anemia by the number of children got higher. 60 percent of mothers of newborns with medical problems had anemia. There was no statistically significant difference in the mean birth weight considering the presence or absence of maternal anemia.

A significant difference between anemia status was not found in terms of mode of delivery and delivery at term. A difference in anemia was not detected in infants no matter their mothers took vitamin and mineral supplements or not.

CONCLUSION: To use iron supplements alone is not enough to prevent anemia in pregnancy, multivitamin use with iron is required. Together iron-multivitamin use reduces the effect of B12 deficiency. It is observed that the frequency of anemia increases while the number of pregnancy increases. In our study it is seen that anemia in the last trimester has no effect on the mode or time of delivery, weight and general condition of newborn.

The taboo of urinary incontinence in Turkish women in wijkgezondheidscentrum De Sleep

Nele Rasschaert¹, Kristin Hendrickx²

¹Ghent University, Family medicine department

²University of Antwerp, Family medicine department

BACKGROUND: Although a very prevalent condition, urinary incontinence (UI) often stays underreported. Only half to 1/3 of the patients consults a doctor. Numbers from the EHR from wijkgezondheidscentrum De Sleep, a family medicine practice in Belgium with 50% of its patients from Turkish origin, showed a very low prevalence. This study determines the prevalence of UI in Turkish women and provides an insight in the roleplaying factors in their help-seeking behavior.

METHOD: A questionnaire, including epidemiological data, the 3 Incontinence Questionnaire, the PRAFAB score and a survey on the attitudes about urine loss, was translated to Turkish. All 18+ women from Turkish origin were invited to participate. The data were analyzed by SPSS. The qualitative part of the study consisted of in-depth interviews and the analysis by NVIVO.

RESULTS: 57,5% of the patients reported involuntary urine loss. 35,1% of these patients consulted a doctor. The

consultation rate increased as severity, 'bothersomeness' and frequency of urine loss rose. The most quoted reason for not seeking help are 'My health is in the hands of Allah', 'Urine loss is a normal consequence of having children' and 'I think the doctor will not consider this important enough to listen carefully'. The qualitative interviews confirm the role of severity and 'bothersomeness' on the consultation rate.

CONCLUSION: Urinary incontinence remains a significant but underreported problem. Urinary loss can occur at young age. This advocates the promotion of pelvic floor muscle training pre- and postnatal for prevention of UI. Only one third of the patients with UI consulted the doctor. The low help-seeking behaviour can be explained by the low severity and 'bothersomeness', and by the lack of knowledge about causes and treatments of urine loss. Information-giving and shared decision making remains therefore an important task. Shame is not an inhibiting factor for seeking help.

Physical performance and 25-hydroxyvitamin D: a cross-sectional study of pregnant Swedish and Somali immigrant women and new mothers

Paul Kalliokoski¹, Yngve Bergqvist², Monica Löfvander³

¹Dpt of Public Health and Caring Sciences, Family Medicine and Preventive Medicine Section, Uppsala University, Sweden

²Centre for Clinical Research Dalarna, Falun, Sweden

³Division of Family Medicine, Dpt of Neurobiology, Care Sciences and Society, Karolinska Institutet, Huddinge, Sweden

BACKGROUND: Vitamin D deficiency can impair muscle strength. Study aims were to examine physical performance in hands and upper legs and analyze plasma 25-hydroxyvitamin D (25(OH)D) concentrations in women with presumably low (veiled, Somali-born) and high levels (unveiled, Swedish-born).

METHODS: Women (n=123, 58% Swedish) enrolled at a Swedish antenatal clinic, were recruited. Plasma 25(OH) D was analyzed (nmol/L). Maximal hand grip strength was tested (Newtons, N), and upper leg performance(able/unable to perform squatting, standing on one leg and lifting their hips). Non-parametric statistics tested the data for differences in their ability to perform the tests. Undetectable values (<10 nmol/L) were replaced with '9' in the linear correlation statistics. A final main effect model for grip strength (in N) was calculated using stepwise linear regression for independent variables: country of birth, 25(OH)D levels, age, height, weight, physical activity, lactation status, parity, and gestational age.

RESULTS: Somali participants (35%) had 25(OH)D levels of <10 nmol/L, and 90% had <25 nmol/L; 10% of Swedish participants had <25 nmol/L of 25(OH)D, and 54% had <50 nmol/L. Somali women had weak grip strength compared with Swedish women: median 202 N (IQR 167–246) vs. median 316 N (IQR 278–359). Somali women were also weak in upper leg performance: 73% were unable to squat, 29% unable to stand on one leg, and 21% could not lift their hips; most Swedish women could perform these tests. In the final model, grip strength (N) was significantly associated with 25(OH)D levels (B 0.94, p=0.013) together with Somali birth (B -63.9, p<0.001), age (B 2.5, p=0.02) and height (B 2.6, p=0.01).

CONCLUSIONS: Many Somali women had undetectable/severely low 25(OH)D concentrations and pronounced hand and upper leg weakness; grip strength was strongly associated with 25(OH)D. Maternity health care personnel should be aware of this increased frequency and manage care accordingly.

Intrauterine Device Slip

Neslihan Erkuran¹, Selami Kara², Esin Taçol³

¹Spc, T. C. Ministry of Health Gölyüzü A.S.M., Bolu, Turkey

²Spc, T. C. Ministry of Health Bahçelievler A.S.M., Bolu, Turkey

³GP Dr, T. C. Ministry of Health Sarıçam T.S.M., Adana, Turkey

INTRODUCTION: Intrauterine devices (IUDs) is one of the long-acting reversible contraception method. In such a case, the IUD must be removed. In this study, we aimed to identify general socio-demographic data of patients with IUD shifted and factors in affecting early and late shifting of IUD.

MATERIALS-METHODS: The prospective, cross-sectional and descriptive study was performed between January and May 2012. For this study, we included 39 patients that they came 2. Mother and Children's Medical Center in Adana for any reason and they were determined to have the IUD shifted. A questionnaire including datas of socio-demographic, childbearing-related information and complaints about the IUD was administered to the patients in the study. IUD shifting in first six month was assessed as shifted early and the others were assessed as shifted late. The data were collected through surveys and analyzed statistically using SPSS 15.0 software.

RESULTS: The shifted IUDs were identified in 39 of the patients which admitted to the clinic at the time of the study. the average age of these patients was found 29.3 (min:17, max:46). The average age of marriage and pregnancy were found 20.6 (min:14, max:29) and 21.1 (min:15, max:30), respectively. The average times of IUDs shifting in the study were identified 15.9 months (min:1, max:72). it was found to have early shifting in 18 patients (46.2%) and late shifting in 21 patients (53.8%) in the study. There were statistically significant differences between smoking, history of heavy lifting, genital infection, age of marriage, type of delivery, breastfeeding, time of IUD administration and early-late shifting of IUD (P:0,429, P:0,273, P:0,454, P:0,406, P:0,115, P:0,956, P:0,139).

CONCLUSION: There were not statistically significant differences between smoking, history of heavy lifting, genital infection, age of marriage, type of delivery, breastfeeding, time of IUD administration and early-late shifting of IUD.

³Ankara Numune Training and Research Hospital(ANEAH) Department of Biochemistry

⁴Ankara Numune Training and Research Hospital(ANEAH) Department of Endocrinology

⁵Hitit University Faculty of Medicine Department of Family Medicine

INTRODUCTION: This study aims to explore whether Vitamin D replacement in primary dysmenorrheic patients with severe Vitamin D deficiency (25-OH-D vitamin:0-10ng/ml) causes a more significant decrease in the severity of pain compared to patients with moderate or mild Vitamin D (10-30ng/ml) deficiency.

METHODS: Hundred patients between the age of 18 and 30, diagnosed with primary dysmenorrhea without a history of other disease, with 25(OH)D levels lower than 30 ng/mg were included. Pelvic ultrasonography was done to exclude any gynecological pathology. All patients were questioned for their sociodemographical and physical characteristics, habits, information about menstrual cyclus, character and duration of menstrual pain, whether menstrual pain affects daily life, accompanying symptoms and VAS severity of pain score was determined. All patients were planned for daily replacement therapy for 2 months and a maintaining dose (6 drops of D-Vit3 per day) in the following month.

RESULTS: Of the patients, 23% had mild, 45% moderate, and 32% severe vitamin D deficiency. VAS score and PTH levels were increased by increased Vitamin D levels. ($r = -0,320; p = 0,002; r = -0,295; p = 0,003$; respectively). Before the replacement patients' mean Vitamin D level was $13,9 \pm 6,1$ ng/ml, VAS score was 7 ± 2 , and parathormone level was $42,2 \pm 17,4$ pg/mL. While mean Vitamin D level was increased to $31,1 \pm 3,8$ ng/ml after the replacement therapy, mean VAS score decreased to $4,0 \pm 1,5$ and mean parathormone level decreased to $28,6 \pm 8,6$ pg/mL.

Change in the levels of the parameters before and after the treatment was shown by Delta(Δ). Accordingly, Δ Vitamin D level was found to be negatively correlated with Δ VAS score and Δ PTH level ($r = -0,421; p < 0,001; r = -0,380; p = 0,024$; respectively). Change in VAS score and PTH levels after the replacement(Δ) was higher in patients with severe Vitamin D deficiency, compared to patients with mild and moderate Vitamin D deficiencies.

CONCLUSIONS: Vitamin D deficiency might be a factor to aggravate dysmenorrhea and proper management might increase patients' quality of life.

Because Touching is Worth More than a Thousand Images

Joana Guerra Silva¹, Ana Franganito Sardo¹, Pedro Filipe Alves¹, Maria João Nobre²

¹USF Mirante, ACES Central I, Olhão, Algarve, Portugal

²USF Guadiana, ACES Sotavento, Castro Marim, Algarve, Portugal

BACKGROUND AND AIM:

Due to its close and long contact with the population, Primary Health Care constitutes an opportunity for preventing and detecting diseases, frequently not valued or perceived by the patient. The aim of this presentation is to show the importance of a complete approach to the patient, and that the information taken from the practical skills may be richer than diagnosis complementary exams.

METHODS: Case report.

RESULTS:

Female, 54 years old, born and resident in Olhão, divorced, with 3 children, with whom she lives. Antecedents of dyslipidemia and L5-S1 discal herniation.

The patient went to her Family Physician (FP) in July/2013 in order to actualise her Cervical Cancer Screening. No complaints were presented. A partial health evaluation was done, namely breast examination. A left supraclavicular ganglion was noticed and biopsied. The result showed a poor differentiated carcinoma, of unknown origin, probably in the breast (oestrogen receptors+).

The patient was sent to the Gynaecology department in Algarve's Hospital, beginning an investigation to locate the primary tumour - mammography, breast ultrasound and magnetic resonance, suprapubic and endovaginal ultrasound, chest radiography, thoracic-abdomen-pelvic TAC and bone scintigraphy, none of which revealed any alterations. Finally, a PET showed caption areas on the right ovary and among multiples ganglion chains.

A total hysterectomy and double anexectomy were performed. The histologic diagnosis was that of a double ovarian poor differentiated serous carcinoma, with lymphatic invasion. Presently, the patient is under palliative chemotherapy, going periodically to her FP to share her evolution.

CONCLUSION:

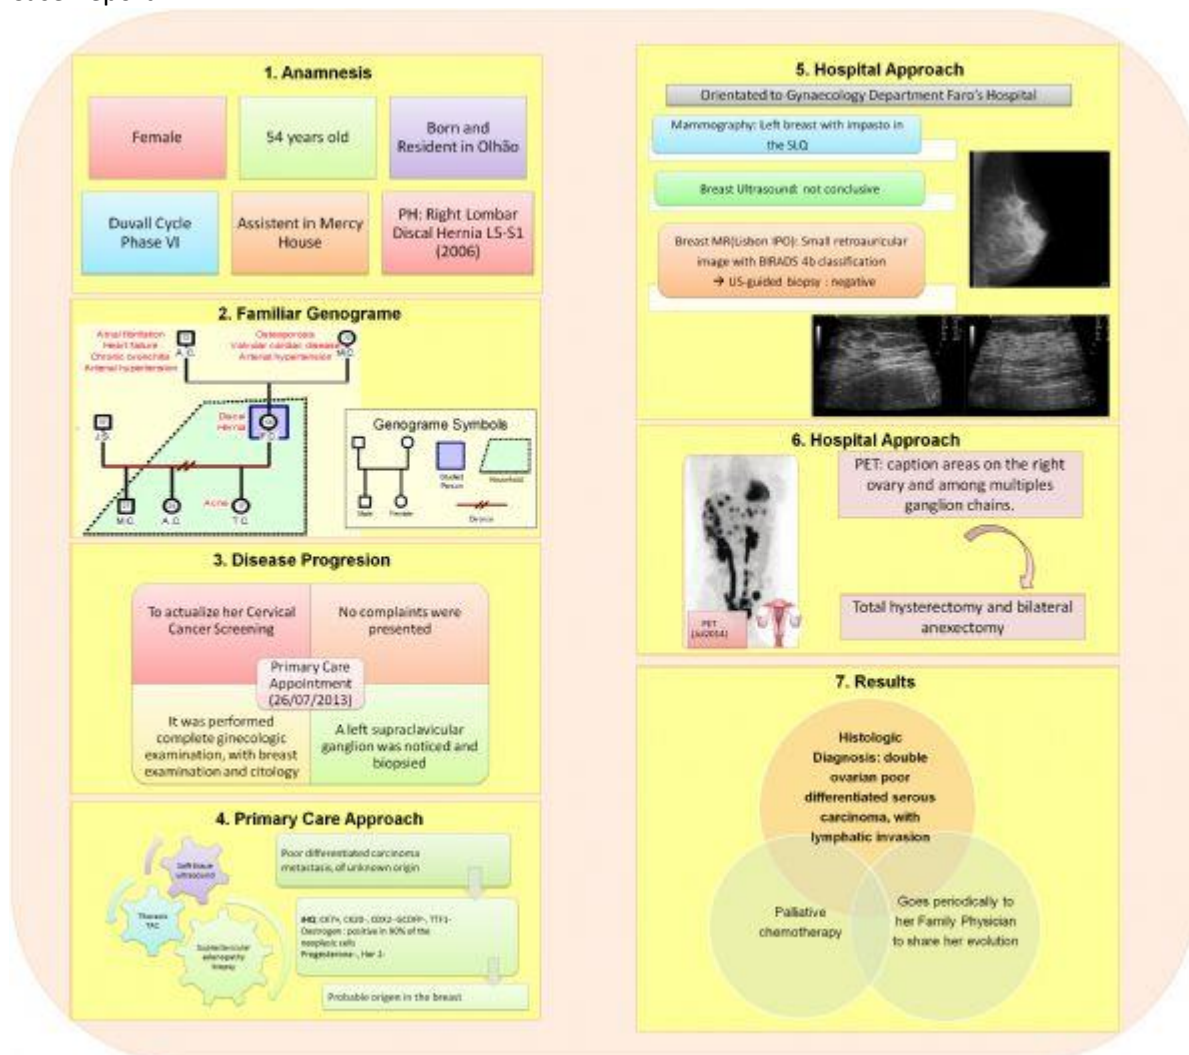

The FP is in a privileged position to intervene on the population. Performing an adequate physical examination – a breast examination in the context of a gynecological evaluation – resulted in the detection of a major pathology with great repercussions in the patient's life, concerning both the physical component, and her psychosocial-family context.

Keywords: Primary Care; Preventing; Cervical Cancer Screening;

Background and Aim

Due to its close and long contact with the population, Primary Health Care constitutes an opportunity for preventing and detecting diseases, frequently not valued or perceived by the patient. The aim of this presentation is to show the importance of a complete approach to the patient, and that the information taken from the practical skills may be richer than diagnosis complementary exams.

Case Report

Conclusion

The Family Physician is in a privileged position to intervene on the population. Performing an adequate physical examination – a breast examination in the context of a gynecological evaluation – resulted in the detection of a major pathology, not detected by the several complementary exams performed, with great repercussions in the patient's life, concerning both the physical component, and her psychosocial-family context.

Evaluation of The Level of Knowledge, Attitudes, and Behavior of Pregnant Women Toward Drug Use During Pregnancy

Numan Güvenç¹, Hamit Sırrı Keten², Celal Kuş¹, Nagihan Sarı¹, Hüseyin Üçer¹, Önder Ercan³

¹Department of Family Medicine, Medical Faculty, Kahramanmaraş Sutcu Imam University, Kahramanmaraş, Turkey

²Department of Family Medicine, Kurtul Family Health Center, Kahramanmaraş, Turkey

³Department of Obstetrics and Gynecology, Medical Faculty, Kahramanmaraş Sutcu Imam University, Kahramanmaraş, Turkey

BACKGROUND: The aim of the present study was to evaluate the level of knowledge, attitudes, and behavior of pregnant women toward drug use during pregnancy.

METHODS: The present study included pregnant women who were admitted to the outpatient clinics at Kahramanmaraş Sütçü İmam University Faculty of Medicine between March 3, 2015 and April 3, 2015. The participants were provided information before the study, and 208 pregnant women, who provided informed consent, were included in the study.

RESULTS: The mean age of 208 pregnant women was 28.20 ± 5.96 years (min=17, max=43). The mean gestational age of the participants was 30.67 ± 9.97 weeks (min=6, max=40). Of participating pregnant women, 139 (66.8%) reported that they had a sufficient level of knowledge regarding drug use, whereas 69 (33.2%) women reported an insufficient level of knowledge. Of the participants, 44 (21.2%) reported drug during pregnancy before they knew that they were pregnant. Of the participants, 48 (23.1%) reported that they bought non-prescription drugs from the pharmacy and 160 (76.9%) reported that they did not buy non-prescription drugs from the pharmacy. Of the pregnant women, 178 (85.6%) reported that they read the package insert and 30 (14.4%) did not read the package insert. Of the participants, 75 (36.1%) reported that they were aware of the risk categories of medicinal drugs and 133 (63.9%) were not aware of risk categories. Of the participants, 100 (48.1%) agreed, 25 (12.0%) disagreed, and 83 (39.9%) had an idea about the expression, "The women should take folic acid before becoming pregnant."

CONCLUSION: The study showed a considerable lack of knowledge and false attitudes and behavior toward drug use during pregnancy.

Contraception Methods in Unplanned Pregnancy

Burçin Kavaklı Geriş¹, Memnune Çiğdem Apaydın Kaya²

¹Burçin Kavaklı Geriş, Department of Family Physician, Marmara University, İstanbul, Turkey

²Memnune Çiğdem Apaydın Kaya, Department of Family Physician, Marmara University, İstanbul, Turkey

INTRODUCTION:

Unplanned pregnancy is one of the serious problems for woman and child. The aim of this study is to assess the use of contraceptive methods among unplanned pregnancy before the in-depth interview.

MATERIAL-METHODS:

Voluntary pregnant women who have visited Marmara University Obstetric Outpatient Clinic in two months and willing to join in-depth interview were included to the study. The pregnant women who are at the last week of pregnancy, recommended for a bed rest, have labor pain, are not included. Socioeconomic status with contraceptive use last one year before the pregnancy was questioned with face to face interview.

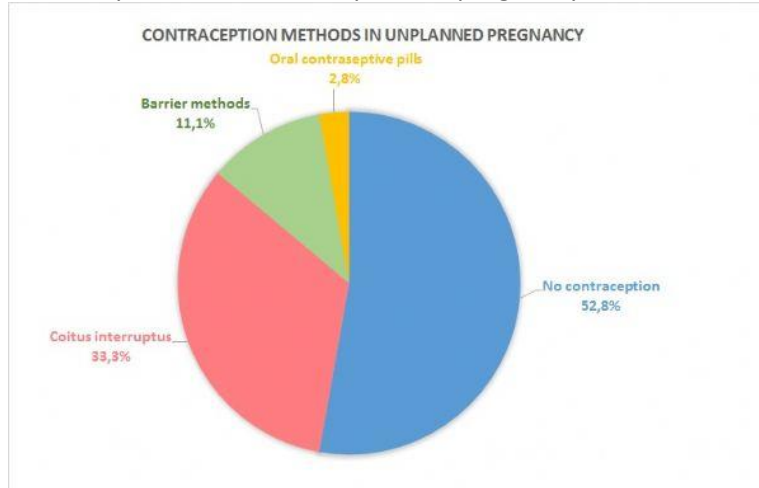

RESULTS: 111 women voluntary pregnant women were included to the study. The mean age of them was 28 ± 4.98 ; mean number of pregnancy was 2.55 ± 1.26 . 36 of 111 pregnancy (32.4%) was unplanned. 52.8% of the women have unplanned pregnancy didn't use any contraceptive method. The contraceptive methods which are used by women who have unplanned pregnancy are coitus interruptus 33.3%; 11.1% barrier methods; 2.8% oral

contraceptive pills and no intrauterin contraceptive device.

CONCLUSIONS: The high prevalence of unplanned pregnancies and low prevalence of contraceptive use among them suggest the need for education to improve women's knowledge about how and when to use the methods in order to increase their ability to plan their pregnancies. Our second plan is to investigate the problems with using the contraceptive methods in that voluntary pregnant with in-depth interviews.

Health Perception and Depression in Women

Yusuf Burak Çayırılı¹, Ekin Nurhan¹, Nihat Birtane¹, Çavuş Ece¹, Burçin Göğüş¹, Çiğdem Apaydın Kaya²

¹Marmara University School of Medicine, Istanbul, Turkey

²Marmara University School of Medicine, Department of Family Medicine, Istanbul, Turkey

Background and AIM: In clinical trials determined that women have more depression signs than the men. Depression may affect the health perception potentially owing to its capability of changing humans' thoughts, feelings and mood. The aim of this study is to determine the association between depression and health perception among women in Turkey-Zümrütevler district.

METHOD: This cross-sectional study was conducted on 210 houses in order to reach women aged 15 and older. The houses were selected by 30x7 cluster selection method in Zümrütevler in April 2015. 30 street and in each street 7 houses were selected randomly. The data was collected through face to face questionnaire covering socio-demographic factors and quinary likert scale to determine the health perception and BECK depression scale was filled by women. According to the BECK scale ≥ 17 was accepted as "depression". SPSS 20.0 was used for analysis. After frequency distributions, chi-square test was applied and Pearson correlation coefficient was calculated.

RESULTS: In 210 house, 173 women with a mean age of 40 ± 1.12 were reached. The average score of BECK depression scale was 15 ± 11.4 (min:0, max:53). Depression prevalence of the women were 32%. There were no association between education, income and BECK score ($p > 0.05$). A statistically significant association was determined in between general health perception and BECK score. The average BECK score was higher in the women reported their general health status as "middle-bad" than the "good-perfect" (17 ± 13.86 ; 12 ± 9.19 ; $p = 0.018$). Having more number of children and pregnancy were positively correlated with BECK score ($r = 0.268$, $p = 0.003$; $r = 0.294$, $p < 0.001$). But married and pregnancy at early ages were negatively correlated with BECK score ($r = -0.240$, $p = 0.003$; $r = -0.245$, $p = 0.03$).

CONCLUSION: In conclusion, about one third of women were in depression and a significant association in between depression and general health perception is determined. Depressed women perceive their own general health worse.

Female Sexual Dysfunction in Diabetes

Nicole Santos Marques, Clara Gameiro Mendes, Ana Bastos Dias, Mariana Oliveira Lemos
USF Monte Pedral

Background & AIM: Diabetes Mellitus (DM) is one of the most common chronic diseases and long-term microvascular and macrovascular complications are a leading cause of morbidity and mortality in DM. Endothelial, vascular and neurological impairment have been associated with erectile dysfunction in men. However, although DM affects about 441 600 portuguese women, the influence of DM on female sexuality is often omitted and overlooked in clinical practice.

The aim of this work is to provide an overview of the epidemiology of Female Sexual Dysfunction (FSD) in diabetic women and discuss the impact of DM on female sexuality.

METHOD: A search for randomized controlled trials, meta-analysis, reviews and guidelines published in English, with the MeSH terms “sexual dysfunction”, “diabetes” and “women” was conducted in PubMed, Cochrane Library, EMBASE, National Guideline Clearinghouse, UpToDate and NICE.

RESULTS: The search returned a total of 113 publications, of which were selected 24. The prevalence of FSD is high among diabetic women and female sexual function index (FSFI) is lower in DM patients than in women without DM. Most studies indicates that prevalence of lower sexual satisfaction, dyspareunia, loss of libido and problems with orgasm, lubrication and arousal are higher in diabetic women. No strong association was found with duration of diabetes or cardiovascular and metabolic risk factors but depression seems to be a main predictor of FSD in DM.

DISCUSSION: DM significantly increases the risk of FSD regardless of metabolic control or duration of the disease. FSD is a complex disease in which biopsychosocial factors have an important role. In fact, as a chronic disease, DM has impact on self-image, family welfare and quality of interpersonal relationships and it can interfere negatively on all aspects of sexual response. Health care providers should address DM holistically, actively questioning the presence of DSF.

Keywords: Diabetes; women; sexual dysfunction

Main causes of cardiovascular deaths in childbearing age women in Goiânia, GO – Brazil

Davison Rodrigues Lima Oliveira¹, Lara Louise Guimaraes Silveira¹, Gustavo Aguiar Alvarenga Amorim¹, Wallace Pinheiro Rodrigues¹, David Carvalho Resende¹, Ana Luisa Franco Moura¹, Lorena De Almeida Ribeiro Prudente¹, Vinicius Bernardes Mendonça Damasceno¹, Camila Garcia De Souza²

¹Faculdade de Medicina, Universidade Federal de Goiás, Goiás, Brasil

²Pontificia Universidade Catolica de Goias, Goias, Brazil

Cardiovascular diseases are the main causes of death in a global standardized view. The impact is not only financial as a lot of money is spent, but is also social with increased years of life lost. The objective of this study is to point the main cause of cardiovascular deaths of childbearing age women in Goiânia. This is a descriptive study conducted in the Health Information Division of the epidemiology department of health in the city of Goiânia- GO. Declarations of deaths of women in childbearing age (10-49 years) living in the city of Goiânia –GO were used as tools to collect data, as well as data on deaths of women in fertile age available at the SUS Informatics Department (DATASUS). We observed that the three main causes of death were responsible of 62 deaths, the equivalent of 13% of the deaths in the city during the year. The first cause described as 'heart disease' counted 29 deaths during the year of 2013. The second one was stroke with 18 deaths followed by acute myocardial infarction (AMI) with 15 deaths in total. The gathered data was not as revealing as it was expected. Although stroke and AMI was described as very important diseases that have to have attention, Twenty-nine deaths of the sixty-two total analyzed has no specific cause. Facts like these impairs the designing of useful strategies that could be applied. Health programs are essential to improve the health of populations, but it is not possible to plan them without knowing what the main problem affecting them is. By this way, it is also important the way the data was published and, in this case, how the doctors are filling the death certificate. Therefore, the education of physicians to fill the certificates with seriously is important to future analysis.

Keywords: Woman, Cardiovascular diseases, cardiocascular deaths

Breast Self-Examination and Breast Cancer Awareness Among Patients Admitted to Family Medicine Outpatient Clinic

Fatma Gönül Doğan¹, Didem Kafadar²

¹Vize State Hospital, Kırklareli, Turkey

²Bağcılar Training and Research Hospital, İstanbul, Turkey

AIM: In the world 23% of women living with cancer have breast cancer. Breast self-examination(BSE) is one of the methods of raising awareness among women and starts at 20 years. Screening programs for breast cancer begins at 40 years for early detection and mamography is the golden standard. We aimed to evaluate the awareness of the patients in the family medicine(FM) outpatient clinic about breast cancer and BSE.

MATERIAL-METHOD: In our study, in a provincial state hospital close to the rural area a questionnaire was applied to the voluntary women patients over 20 years of age in the family medicine outpatient clinic. The questionnaire was prepared by the researchers and asked about attitudes towards mamography and BSE.

RESULTS: There were 155 women, the mean age was 44.13. Patients were mostly in 40-64 age group(%48.4). 58% of patients had 5 years of primary education(PE). 78.7% patients were married. 80 women(51.6%) performed BSE. 33.3% of the illiterate patients were aware of BSE. Among graduates of 5 years PE, 8 years PE and high school, the BSE performance percentages were 45.5, 68.7 and 83.3 respectively. 35% of patients performed BSE every month regulary. 42.7% patients who did not perform BSE reported that they did not know how to do BSE. History of mamography screening was 22.6% in the whole group and it was 37.3% in 40-64 age group, 26.7% in patients who were 65 and over. The patients reported that they obtained information about breast cancer and BSE mostly from television and then from friends, gynecologists, general surgeons and FM practioners respectively.

CONCLUSION: In our study, the lowest awareness of BSE was in the illiterate group, as education level increased the BSE increased. FM practioners should provide adequate information about breast cancer, screening and BSE in terms of secondary prevention.

Evaluation of Cases with Postmenopausal Bleeding

Tuba Ömeroğlu, Zehra Dağlı, Zeynep Bayraktutar, Ayşe Selda Tekiner, Mehmet Ungan
Department of Family Medicine, School of Medicine, Ankara University, Ankara, Turkey

OBJECTIVE: Postmenopausal uterine bleeding mainly originates from endometrial polyps, endometritis, exogenous hormone uptake, submucous myoma, atrophic vaginitis and endometrial carcinoma. Further investigation is essential particularly to exclude endometrial carcinoma. The study was carried out to detect prevalence of endometrial carcinoma in patients with postmenopausal bleeding.

METHOD: Medical records of 108 patients who applied to the gynaecology outpatient clinic of a university hospital for postmenopausal bleeding between 2011 and 2012 were reviewed retrospectively. As the results of endometrial biopsy five patients were missing, 103 patients were included in the study. The patients were categorized in four age groups. Descriptive statistics were given as mean±standard deviation and percentage. Chi-square test was used for differences between the groups. Any $p < 0.05$ was considered statistically significant.

RESULTS: Mean age of the patients was 56.91 ± 8.70 (median, 56; minimum, 39; maximum, 84) years. Seventeen (16.5%) of the patients were ≤ 49 , 52 (50.5%) were 50-59, 23 (22.3%) were 60-69, and 11 (10.7%) were ≥ 70 years old. Eleven (10.7%) patients had endometrial carcinoma, and nine (8.7%) had endometrial hyperplasia. Two (18.2%) of the patients with endometrial carcinoma were 50-59, six (54.5%) were 60-69, and three (27.3%) were ≥ 70 years old. Three (33.3%) of the patients with endometrial hyperplasia were ≤ 49 , four (44.4%) were 50-59, one (11.1%) was 60-69, and one (11.1%) was ≥ 70 years old. The difference between the groups was statistically significant ($p=0.040$).

CONCLUSION: All patients at menopausal period should be informed about the risks of endometrial carcinoma,

70% of which occurs between 45-74 years, and should be advised to consult their family physician when they have postmenopausal bleeding.

Keywords: postmenopausal bleeding, endometrial carcinoma, family physician

P-0775

Primary amenorrhea: A Case Report

Ahmet Ünal¹, Ahmet Anık², Tolga Ünüvar²

¹Department of Family Medicine, Adnan Menderes University, Aydın, Turkey

²Department of Pediatric Endocrinology, Adnan Menderes University, Aydın, Turkey

INTRODUCTION

Primary amenorrhea can be diagnosed if a patient has normal secondary sexual characteristics but no menarche by 16 years of age. If a patient has no secondary sexual characteristics and no menarche, primary amenorrhea can be diagnosed as early as 14 years of age. The incidence ranges from 0.1% to 2.5%. The most common cause of gonadal failure, and congenital absence of uterus and vagina constitutional delay.

CASE REPORT

Fifteen-year-old female patient was admitted with complaints of amenorrhea. It didn't feature in the history of the patient and family history. On physical examination; body weight was 47.5 kg (10-25p), height 149 cm (3p) and body mass index of 21.4 (50-75p) that found. There were no pathological findings in systemic examination. Breast development and pubic hair were evaluated according to Tanner stage 4. Laboratory tests were within normal limits. For the etiology of secondary amenorrhea beta-human chorionic gonadotropin (β -hCG) level is negative (<1.2 mIU/ml) determined by the patient's serum follicle stimulating hormone (FSH) 7.19 mIU/mL (N: 3.35 to 21.63), luteinizing hormone (LH) 11.62 mIU/mL (N: 2.39 to 6.6), prolactin 18.36 ng/mL (N: 1.2 to 29.93), respectively. Thyroid function tests were normal. Patient's bone age 14 years. The patient's pelvic ultrasonography (USG) were within normal. Considering progesterone failure, patients have started medroxyprogesterone acetate 5 mg for 10 days. 5 days after drug withdrawal patient first menstrual period occurred. The patient underwent the same treatment for three cycles, patient's menstrual cycle became regular and were followed.

CONCLUSION

Detailed story, detailed physical examination and laboratory findings of the evaluation of secondary sex characteristics are important in diagnosis. Primarily, pregnancy should be excluded, thyroid function tests, prolactin, FSH, LH, estradiol levels should be measured and pelvic ultrasonography should be performed to assess the genital organs. According to FSH levels it can be classified as normogonadotropik, hypergonadotropic and hypogonadotropic hypogonadism. Karyotype analysis should be performed in cases of hypergonadotropic hypogonadism, hypogonadotropic hypogonadism cranial imaging in cases to be made. Such cases should be made without delay in diagnosis and treatment. Diagnosed in primary care to many patients the chance to be caught with scrutiny.

Breaking Bad News: is the SPIKES strategy known, used, helpful in the clinical practice of a family physician?

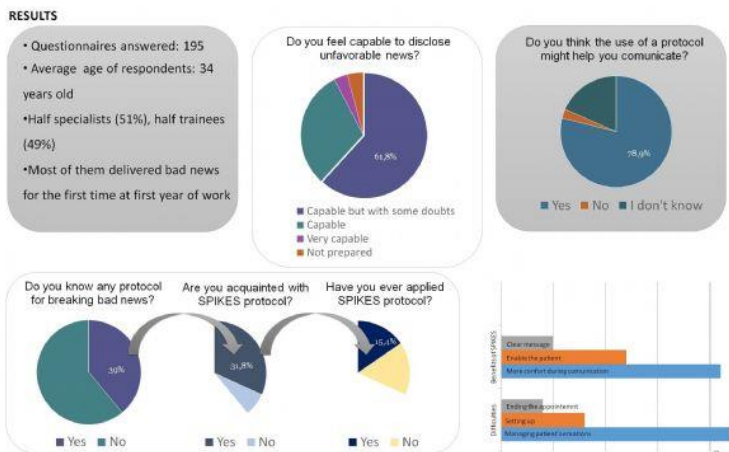

Erica Rocha, Maria Ana Sobral

Unidade de Saúde Familiar AlphaMouro, Rio de Mouro, Portugal

BACKGROUND: The right of any patient to information is consensual, though ethical and moral problems may emerge. As Family Doctors conveying bad news with a strong psychological impact on the patient is a professional and personal challenge. With this study we want to assess whether the Family Doctors feel well prepared for the task of conveying bad news and if they have the urge of improving their abilities. We selected a protocol (SPIKES) in order to confirm whether it is recognized, used in clinical practice and the benefits or difficulties when implemented. **METHOD:** A cross-sectional and descriptive study based on an on-line set of questions sent to specialists and interns in General Practice and Family Medicine; a questionnaire available in Portuguese, with 14 multiple choice and open response questions. **RESULTS:** The situations more frequently reported were those of poor prognosis (56,6%), death and chronic disease (21,6%). Most of the respondents considered themselves prepared for the task, but with some qualms about this kind of communication (57, 3%). 61,4% of the respondents identified the need for education and training in this type of communication as extremely important. Only 39, 8% were acquainted with a communication of bad news protocol. In this group 80% knew the protocol SPIKES but only 36, 7% had implemented it as a communication strategy. Among the professionals who stated the use of this protocol, 19 recognized the management of the patient's emotions as a major problem; 16 reported that a clearer announcement of the news and a greater personal comfort (11) were the main benefits of its application. **CONCLUSIONS:** The announcement of bad news is a fact within the Family Doctor's practice. It will be essential to invest, namely in pre-graduate education focused on communication techniques deemed to ease efficient transmission and management of this type of news.

Background and Aims

Decision-making for someone with dementia at the end of life is complex and challenging. There is a lack of formal guidance about how to manage their needs. Practitioners often subconsciously rely on 'rules of thumb' or heuristics to make decisions about end of life care. A systematic review of the literature was performed to identify whether heuristics formally exist as an entity in palliative dementia care, and if so, to identify the context in which they are being used.

Methods

A search using broad terms related to dementia, palliative care and decision-making was conducted across four electronic databases (MEDLINE, EMBASE, PsycINFO and CINAHL).

Results

The search identified ten papers that contained an algorithm, guideline, decision-tool or set of principles that were in some form compatible with heuristic thinking. The papers addressed swallowing and feeding difficulties, the treatment of pneumonia, management of pain and agitation, ending life-sustaining treatment and ensuring a good death.

Conclusions

The use of heuristics in palliative dementia care is not formally documented in the literature. However, the review has synthesised important decision-making principles that are largely a reflection of expert opinion. These principles have the potential to be developed into simple and easy to use heuristics.

Keywords: Dementia, Palliative care, Decision-making

Table 1: Search Terms

Search Terms	
Dementia	Dementia, Alzheimer disease, delirium, amnestic and cognitive disorders, cognitive defect, cognitive impairment
Palliative Care	Palliative care, terminal care, end of life care, terminally ill patients, death and dying
Decision-making	Decision-making, algorithms, decision support techniques, decision support systems, clinical judgment, heuristic, rules of thumb

Table 2: Summary of selected papers

Theme	Publication	Summary of decision-making concepts
Swallowing and eating difficulties	(McAlister et al., 1989)	Establish the goals of feeding - is it to provide calories/ prolong life/ maintain comfort? Weigh up the risks vs benefits of available feeding options.
	(Smith et al., 2009)	Search for reversible causes of reduced eating. Encourage use of good mouth care. Review and if necessary discontinue constant and distressing attempts to continue feeding.
	(Palecek et al., 2010)	Use the term 'comfort feeding only' to reframe discussions about hydration and nutrition.

	(Gillick, 2012)	Encourage family and carers to recognise that reduced feeding can be a consequence of the dementia disease process. Look for reversible causes. Empirically modify food and hand feed to whatever extent is tolerated.
	(Schwartz et al., 2014)	Literature review - concludes that a decision to forgo artificial hydration and nutrition is in line with current evidence. Encourages multidisciplinary involvement in decision-making.
Treatment of pneumonia	(van der Steen et al., 2000)	Evaluates the use of a checklist developed in The Netherlands to make decisions about whether or not to treat pneumonia. Consider risks vs benefits of treatment. Consider the best interests' of the patient above all.
	(van der Maaden et al., 2014)	Five round Delphi study looking at optimal symptom relief of pneumonia <ul style="list-style-type: none"> • Measuring oxygen saturation does not help with the management of shortness of breath • Give oxygen if shortness of breath is burdensome • In patients with chronic obstructive pulmonary disease and shortness of breath – use corticosteroids, bronchodilators and opioids • A burdensome cough warrants opioids • There is no evidence that anticholinergics reduce sputum retention and rattling breath
Pain and agitation	(Kovach et al., 2012)	Evaluates the use of a 5-step and a 9-step decision support tool used to address pain and agitation -address the physical and environmental needs of the patient and then target symptoms with interventions. Balance sensory stimulating and sensory calming activity, trial analgesia before antipsychotic medication and review treatments regularly.
Rationalising medication	(Zagaria, 2015)	Medication not in line with the primary goals of care should be stopped. Cholinesterase inhibitors should not be prescribed for dementia, without periodic assessment of the perceived cognitive benefits and adverse gastrointestinal effects.
Ensuring a good death	(Cahill et al., 2012)	Uses information from interviews with bereaved spouses to identify a set of principles to support dementia end of life care in nursing homes: Individualised care Excellent personal care Integration of nursing homes with local healthcare systems Foster a sense of partnership between staff, residents and families.
	(Karlawish et al., 1999)	Describes a process of how to reach consensus in decision-making: Identify key decision-makers, establish dialogue and put knowledge about the patient in the foreground; then seek consensus about the current diagnosis and prognosis.
Ending life-sustaining treatment	(Callahan, 1995)	No one should live longer with advanced dementia than they would have done in the pre-technological era. In late-stage dementia there should be a shift towards stopping rather than continuing treatment.

Japanese nurses' experiences with life-support treatment and its impact on decision-making

Fumio Shaku¹, Madoka Tsutsumi²

¹Nihon University Itabashi Hospital

²Tsukuba University

Background & Aim

The Japanese sense of decision making (like OMAKASE, which means "to entrust") differs from that observed in Western countries. Recently, the decision making for terminal care patients has been discussed widely. However, it is suggested that many patients and their family members make such decisions without adequate information. In the clinical setting, we feel that it is tough for many patients and their family members to make a decision, partially because they may not be aware of the severity of the situation. Therefore, we studied how the practical experience of nurses working at hospitals influences their decision making.

Method

Self-reported questionnaires on nurses' attitudes toward life-support treatment in case it were intended for themselves or their family member in the terminal stage for cancer and non-cancer situations, and their experiences related to their patients' death, were distributed to 600 nurses working at five hospitals in Japan.

Results

In total, 475 questionnaires were returned, out of which 391 (67.9%) completed questionnaires were analyzed. The mean age of the participants was 40 ± 10.6 years, and 95.7% were females. Further, 345 of them had experience with patient death. Those hoping (hope group) or not hoping (no hope) for family's life-support treatment for cancer were 255 and 136, respectively, and the same in non-cancer situations were 275 and 116, respectively. The median of experience with patient death in the no hope group was significantly higher than that of the hope group ($p < 0.005$).

Conclusions

It is suggested that higher the experience with patient death, lesser is the hope for life-support treatment for oneself or one's family member. Based on this result, it is clear that thorough discussion regarding the reality of the situation with the medical staff seems to be indispensable to the decision making for a patient and his/her family.

Fentanyl pectin nasal spray as treatment of breakthrough pain in terminal patients with amyotrophic lateral sclerosis

Pablo Alvarez Jimenez, Antonia Quiñones Perez, Karolina Wawrzycka
Närhälsan Mariestad Vårdcentral, Västra Götalandsregionen, Sweden

PURPOSE:

Amyotrophic Lateral Sclerosis (ALS) is a neurodegenerative disease characterized by a gradual death of motor neurons that causes atrophy of the voluntary muscles producing muscle and respiratory function disorders. The majority of the people affected by this disease, which causes great suffering, die a few years after diagnosis, although some can survive more than ten years.

Patients may show symptoms such as muscle weakness, atrophy, hyperreflexia, pain or bulbar symptoms such as dysphagia, dysarthria and shortness of breath. With the progression of the disease, these symptoms cause new and problematic conditions for patients with ALS, orally administrated medicament can be difficult in the stages advanced by dysphagia.

Pain is an aspect of the disease that is commonly passed by high, undervalued and potentially undertreated in ALS patients, and this becomes more evident when we talk about breakthrough pain (BTP).

CASE:

We present a case of advanced ALS with progression of the disease symptoms dyspnea, dysphagia and skeletal muscle pain which are crisis of BTP with flaccid and loss of muscle tone to cervical and upper limbs. The management of dyspnea and basal pain became controlled with slow-release morphine (340 mg per day) and fentanyl pectin nasal spray (200 mcg) for BTP was used. The patient and his family express the speed of action of fentanyl pectin nasal spray and the ease of management and safety of this medication.

CONCLUSIONS:

Pain is a common symptom in all stages of the ALS, being an aspect of the disease that commonly overlooked and a high percentage of the time is below diagnosis and treatment. Morphine is safe for the management of pain and dyspnea in ALS patients. The muscular component of pain in these patients, with sagging and loss of tone, responds adequately to the fentanyl. Side effects have not been described.

A case of idiopathic Trachyonychia

Adem Parlak¹, Nehir Parlak², Salim Özenç³, Yusuf Emrah Eyi⁴

¹Department of Family Medicine, President Guard Regiment, Ankara, Turkey

²Department of Dermatology, Etimesgut Public Hospital, Ankara, Turkey

³Department of Family Medicine, Diyarbakır Military Medicine, Diyarbakır, Turkey

⁴Department of Emergency Medicine, President Guard Regiment, Ankara, Turkey

INTRODUCTION: Trachyonychia or rough nails, may present as an idiopathic disorder of the nails or it can be associated with other dermatological conditions. The dystrophic nail findings seen in trachyonychia are characterized by brittle, thin nails, with excessive longitudinal ridging. The most common histopathologic features associated with trachyonychia are spongiosis and exocytosis of inflammatory cells into the nail epithelia; typical features of lichen planus or psoriasis can also be detected. Determining the cause of trachyonychia is challenging. Trachyonychia is much more common in children, with an insidious onset and peak age of 3 to 12 years. However, it can occur at any age. Trachyonychia can be a manifestation of a pleomorphic group of disorders or can be idiopathic

CASE: We report the clinical features in the eighteen-year-old male with idiopathic trachyonychia (twenty-nail dystrophy). Both finger and toe nails findings seen in trachyonychia are characterized by brittle, thin nails, with excessive longitudinal ridging. This gives the nail plate a rough, opaque appearance. Trachyonychia have been no associated with alopecia areata, psoriasis, lichen planus, atopic dermatitis, ichthyosis vulgaris, as well as other skin conditions.

CONCLUSION: A comprehensive review of the literature reveals that there is no single evidence based treatment for trachyonychia. Therefore, there is no universally accepted treatment for this chronic disorder and many options have been discussed in case reports. Treatment of trachyonychia is mainly cosmetic as it is not a permanently scarring condition. In patients who desire treatment, there are both topical and systemic options that have been shown in case reports to be successful. Tazarotene gel 0.1%, psoralen plus ultraviolet A (PUVA) and intralesional injection of triamcinolone into the proximal nail fold at a concentration of 2.5-10 mg/ml has been shown to be effective in patients.

Polypharmacy and Irrational Prescribing in Palliative Cancer Patients: Observations from a Tertiary Cancer Hospital in India

Dr Hannah Fox, Dr Rakesh Roy

Department of Palliative Care, Saroj Gupta Cancer Centre and Research Institute, Kolkata, India

Background

The World Health Organization (WHO) estimates that globally, more than half of all medicines are prescribed inappropriately. Irrational use of medicines is a major problem in India. Patients with advanced cancer are especially at risk of polypharmacy.

Aims

- To determine the degree of polypharmacy in advanced cancer patients
- To determine the classes of medicines most commonly prescribed
- To determine if analgesia is prescribed using WHO ladder

Method

The medical records of thirty inpatients admitted December 2014-January 2015 were reviewed. Demographics, primary diagnosis and prescriptions on medicine cards were documented.

Results

The mean number of medications prescribed per patient was 11.7(range 3-29). 77% of patients were taking more than 7 medications.

100% of patients were prescribed proton pump inhibitors. Analgesics were the second most commonly prescribed medication followed by health supplements (63%) and antibiotics (57%).

70% of patients were prescribed analgesia, 53% in line with the WHO ladder. 20% were prescribed step three analgesia.

Conclusions

This study demonstrates that the number of medicines prescribed for advanced cancer patients in India is substantially higher than in Europe (7.8)[1]. Over three-quarters of the patients were taking more than 7 medications, putting them at >80% risk of adverse interactions[2].

Only 20% of patients were receiving strong opioids and approximately half of the patients did not receive analgesia according to WHO ladder. As 85% of advanced cancer patients experience pain, overall management was suboptimal(Twycross, 1996).

This study highlights the wider issues of irrational prescribing in India and the need for improved regulation and policies.

Meditation and Relaxation practice with Palliative Care patients at home

Carmen Carrazoni¹, Manu Pérez³, Elvira Perpinyà², Roser Casas³, Nieves Navas⁴, Maria Diamanti⁴

¹ABS Via Roma - Barcelona - Spain

²CAP Sants – Barcelona

³CSMA Rubí (Barcelona)

⁴CS Almozara – Zaragoza - Spain

Background and Aims

It has been described in Medical literature the usefulness of Meditation and Relaxation practices in a regular way in order to obtain a better acceptance of illness and to reduce the stress produced by oncologic disease in patients and their caregivers. From an experiment carried out in a hospital with 800 patients and their caregivers we decided to try this practice at their homes.

Method

From January 2013 to 2014 the Palliative Care team at home help, offered the possibility of practicing Meditation to patients who were capable of doing it. An expert in this practice went to the patients' home once a week. A guided Meditation, visualization of the somatic scheme, and conscientious breathing, where the patient is aware of their body's sensations, was carried out during 20 minutes. This was followed by three or five minutes of silence and even longer if the patient needed. After the person returned to their consciousness, they could share the experience if they wished so.

Results

17 patients with highly developed cancer participated. Age between 21 and 86 years old. Two patients gave the practice up, because they felt anxiety during the silence. Between 7 and 24 Meditation sessions were carried out with excellent tolerance and acceptance. All professionals that conducted these sessions felt that the patients and caregivers pain, emotions, physiological and spiritual harmony were better managed and their response to this practice was positive.

Conclusions

The result of this experiment suggests that practicing Meditation at oncologic patients' homes is possible and well received. It is effective for pain management and better acceptance of the illness. We believe that this experience should be extended to larger groups of patients and caregivers since this practice may correspond to a valuable holistic complement to cancer treatment for non hospitalized patients.

Arabic-Speaking Individuals' Understanding and Attitudes Towards Hospice and Palliative Care in the Ambulatory Setting

Allison Peddle, Md, Melissa Castaneda, Md, Lesca Hadley, Md, Richard Young, Md
Family Medicine, John Peter Smith Hospital, Fort Worth, Texas, United States

BACKGROUND AND AIM: At John Peter Smith Hospital's International Health Clinic (IHC) in Fort Worth, Texas, we provide comprehensive primary care to various refugee and ethnic minority populations with the vast majority from Africa, Burma, Nepal, and the Middle East. Each population has its own understanding and attitudes of the death and dying process. The purpose of this study is to investigate the understanding and attitudes of Arabic-speaking cultural minorities towards Hospice and Palliative Care (HPC) to help us better understand how to provide culturally sensitive information and care in regards to HPC. **METHODS:** A modified AARP End of Life Questionnaire was translated into Arabic language using a certified Arabic language translator. The questionnaire was mailed to Arabic-speaking individuals identified from IHC database with a return stamped envelope. Questionnaires that were answered and returned to us were then translated into the English language by a different certified Arabic language translator. **Inclusion criteria:** adult Arabic-speaking patients who have moved to the United States within the past five years. **Exclusion criteria:** patients ages less than eighteen and those who do not speak Arabic. Subjects will be asked about their understanding of HPC and their personal experiences of caring for dying patients in their home countries. Sub-analyses will include comparisons of subjects' responses by age, gender and region of origin. **RESULTS AND CONCLUSIONS:** Will be ready in time for conference.

A successful case in a Palliative Care Unity

Sara Neves Costa¹, Mariana Sousa Silva²

¹USF Mactamã, ACES Sintra, Portugal

²UCSP Póvoa de Santa Iria, ACES Estuário do Tejo, Portugal

BACKGROUND:

During medical school we were thought how to save lives but not to tend to their demise. It's important to understand and embrace another perspective of health care that focuses on symptoms palliation when there's no possible treatment. In palliative care the well-being and comfort of the patient is a priority, since the symptomatic therapy can relieve suffering and improve the quality of life during his last days.

CASE:

66 years old male, with a terminal stage gastric adenocarcinoma. Lives with his wife and is independent in daily activities.

The patient was admitted in the Oncology department for etiological evaluation of fever and digestive bleeding. On physical examination he presented poor condition, jaundice and abdominal abscess (previously diagnosed). Blood tests demonstrated cholestasis and severe anemia without clinical criteria for transfusion. It was admitted situation of last days and the patient was transferred for the palliative care unit (PCU).

During hospitalization in the PCU the patient began treatment with dexamethasone for cholestasis and antibiotherapy for the abscess, with improvement of his clinical condition. Consequently he was eligible for transfusion, which helped him recover his previous functional capacity. In order to program a possible home discharge the analgesic therapeutic was optimized and the health staff successfully empowered the patient and family to manage pain medication. After discharge the patient maintained his follow up with the outpatient palliative care team.

CONCLUSIONS:

This reported case shows that admission in a palliative care unit not always ends in patient decease. In some situations we accomplish an appropriate control of the symptoms and make possible the patient discharge to home. Such accomplishment provides better life quality in a terminal disease. This report is also an example of how much can be done when doctors admit there's no possible cure for a terminal disease.

International experience in Palliative Care: Give life to the last days

Sara Neves Costa¹, Mariana Sousa Silva²

¹USF Mactamã, ACES Sintra, Portugal

²UCSP Póvoa de Santa Iria, ACES Estuário do Tejo, Portugal

Background & AIM:

The portuguese postgraduate training program of family doctors includes the optional realization of international rotation. In this context we decided to experience working in the Palliative Care Unit of Hospital de L'Esperanza in Barcelona. This unit is integrated in a structured network of hospital and outpatient care with large experience in this area.

The aim of this presentation is to share our experience. This way we mean to show some aspects of the terminal patient care, including the necessary competences to communicate with the patient and his family and to give a new perspective of health care that focuses on symptoms palliation and not on disease treatment.

Justification:

The holistic approach and the longitudinal continuity of care are two competences and characteristics of the family doctor and are particularly important when treating a terminal patient.

Content:

The Palliative Care Unit of Hospital de L'Esperanza it's part of the Oncology department of Hospital del Mar and receives patients with terminal cancer or other terminal situations that require hospitalization. The primary goal of this unit is to provide the maximum comfort for the patient and his family by controlling physical and emotional symptoms. A multidisciplinary team of doctors, nurses, social workers and other health professionals provides this care and optimizes it for the specific characteristics of each patient. The treatment approaches in this unit do not aim to delay or accelerate the process of dying instead they try to give dignity and a sense of well-being during the last days. In a minority of cases is possible to discharge the patients home when there's a control of symptoms and since there's an excellent support of this patients provided by the family and the outpatient palliative care team.

"The dying patient – the family doctor's role"

Maria Ana Sobral, [Maria José Verdasca](#)

Unidade de Saúde Familiar AlphaMouro, Rio de Mouro, Portugal

INTRODUCTION: Family physicians often accompany people with a poor prognosis in the context of a holistic approach in order to provide comfort and quality of life to the patient and their family. The objective of this work is to stress the family physician's role in managing the fears and expectations of the family of the dying patient.

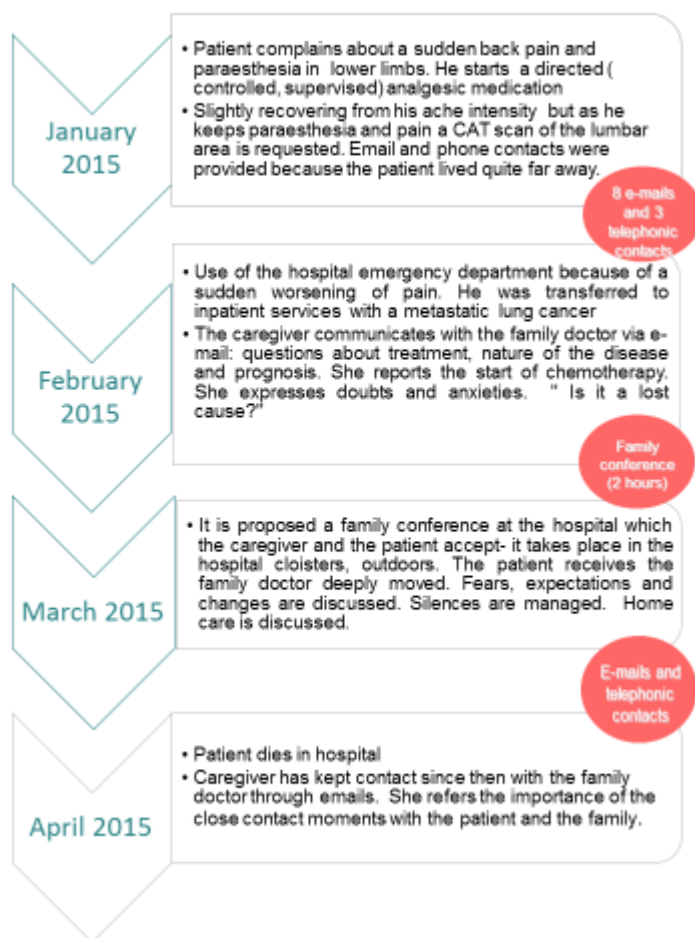

METHODS: Qualitative analysis of a case of a 63 year old male dying patient, admitted to hospital with multiple metastasis lung cancer diagnosis. The wife is the primary caregiver, with the whole family involved in the task. The data were collected through observation, with hospital visits and field notes.

RESULTS: The FPh, contacted by the wife of the patient for concern and anxiety about the diagnosis and prognosis, evaluates, in a first step the patient and family needs. A family conference is set in the internment place to work fears and expectations. A communication channel (telephone and email) is created and that resulted in an apparent decrease in anxiety levels and improved the psychosocial well-being of the patient and the family.

CONCLUSION: It is essential to maintain open communication with the family members of the dying patient. The simple intervention of recognition and support, the availability of communication means, led to a decrease in the family anxiety levels. The doctor's visit to the patient's environment, programming and integrating the family in the process of life and death was perceived as useful by the relatives.

Clinical case and communication strategies

P-0787

Crossed stories

Paula Mendes¹, Vítor Portela Cardoso²

¹USF Maxisaúde, ACES Cávado I, Braga, Portugal

²USF Gualtar, ACES Cávado I, Braga, Portugal

Background and AIM: Lung cancer is the leading cause of death from malignancy in most western countries. Only 5-15 % of lung cancer are detected while asymptomatic. Currently, screening for lung cancer are not recommended. This case demonstrates the dynamics of family medicine in the prevention, diagnosis, treatment, monitoring and palliation.

Method and RESULTS: We report the clinical case of a 50 years-old female patient, caucasian race, formerly working in a textile factory, lower-middle class Graffar. No relevant personal history. No smoking or exposure to known occupational carcinogens. Family history of gastric cancer (paternal grandmother). She went to her family physician in July 2010 to request "routine tests" and pulmonary radiography, because, one month before, her husband had been diagnosed with lung cancer. She felt anxious about the possibility to have a serious illness too. She denied any symptoms. No alterations in the physical examination. Pulmonary radiography was requested, which showed suggestive of lung cancer, confirmed by the computed tomography. Histological diagnosis revealed "moderately differentiated adenocarcinoma mixed pattern". She was submitted to pneumonectomy in January 2011 and chemotherapy and adjuvant radiotherapy. In June 2012, her husband died after a pulmonary embolism, and four months later she also died in a Palliative Care Unit. Throughout the process, the couple was followed up by their family physician.

CONCLUSION: The case presented several challenges. Family physician must not only meet their agenda, often based on standards of clinical practice guidelines, but also the patient's agenda, corresponding to their expectations, their beliefs and their fears or concerns. Thus, it's important to make use of our intuition (gut feelings) in a measured way, in a individualized approach to the patient. Finally, the management of bad news communication of is one of the roles of the family physicians, embracing the support to patients and their families

A New Alternative Treatment For Radiation-Induced Skin Injury; Acupuncture

Abdulsamet Zortul¹, Sultan Oksuz Zortul², Ozlem Ozer²

¹Department of Radiation Oncology, Ataturk University, Erzurum, Turkey

²Department of Family Medicine, Ataturk University, Erzurum, Turkey

Radiation therapy uses high-energy rays (x-rays etc.) or particles (photons, electrons, or protons) to kill cancer cells by damaging their DNA. When the damaged cells die, they are broken down and eliminated by the body's natural processes. But not only cancer cells, normal cells are damaged as well. This is the cause leading to side effects, most of which are short-lived include sore skin, tiredness and hair loss. With longer treatment, these side effects may get worse. After many years, skin cancers may develop in areas previously treated by radiation. In rare cases, radiotherapy can cause significant long-term effects such as infertility or sarcomas. Although these side effects radiation therapy is precious and good choice to cure some cancers and to delay the growth of more advanced cancers. Radiation is also useful when combined with other treatments and may also be used to help treat cancer that has spread to lymph nodes or other organs. It is used to treat cancer or after a surgery as an adjuvant treatment or for palliative therapy.

Acupuncture literally means to puncture with a needle. However, the application of needles is often used in combination with moxibustion (the burning on or over the skin of selected herbs) and may also involve the application of other kinds of stimulation (laser, electroacupuncture) to certain points. In some countries, many skin diseases are treated with acupuncture such as chloasma, acne vulgaris, relieving pain of herpes zoster, promoting formation of scar tissue neurodermatitis and is also known to have an antipruritic effect. Acupuncture improves quality of life if it is applied before and after radiotherapy. It can greatly lessen the adverse reactions on the skin such as skin injury, redness and drying. It also provide protection against damage to haematopoiesis and side effects of digestive and nervous systems.

⁵Narlidere Community Health Center, Izmir, Turkey

⁶Izmir Katip Çelebi University Atatürk Training and Research Hospital, Clinic of Medical Oncology, Izmir, Turkey

BACKGROUND: Palliative care has been implications for terminal stage patients with depleted therapeutic approaches; today, the belief of need for palliative care with curative therapies for patients since beginning of life-threatening diseases is present. Depression and anxiety symptoms found commonly in chronic diseases like

cancer and these symptoms were also common for caregivers of cancer patients. So we aimed detecting and evaluating depression and anxiety symptoms of caregivers of hospitalized cancer patients in Izmir Katip Çelebi University, Atatürk Education and Research Hospital, Palliative Care Services.

METHODS: Study was designed as descriptive cross-sectional research. Survey performed by face to face interviews after obtaining consent of the relatives of the patients. The survey consists of Beck Anxiety Inventory, Beck Depression Inventory, Hospital anxiety and depression scale chapters and socio-demographic variables. The study was conducted with 101 volunteers in a period of three months. The patients' demographic data were summarized using descriptive statistics. Subgroup analyzes were performed using appropriate parametric and non-parametric tests.

RESULTS: In our study, 101 participants had been involved who were caregivers in palliative care. 61 of them (59.8%) were female and 41 (40.2%) were male. As a result of surveys to examine the prevalence of depression; according to Beck Depression Inventory 43.1 % and was found compared to 91.2% with the HAD scale. When the frequency of anxiety was 66.7% with Beck Anxiety Inventory 72.5% was found with the HAD anxiety scale. 39.2% of the people were depressed and 47.1% of the people were anxious according to both scales.

CONCLUSION: For palliative care services, it is important in terms of observing for mood disorders of caregivers and to provide the necessary support for caregivers because study showed that caregivers have been followed in depressed and anxious mood as well as patients.

P-0790

Clinical prediction of survival in terminal cancer patients: individual assessment vs. interdisciplinary assessment

Hyun Soo Yoon, Chul Min Kim, Yong Joo Lee, Jo Hi Yoon, Ha Ji Jung, Eun Kyung Sin

Department of Family Medicine, Seoul St. Mary's Hospital, College of medicine, The Catholic University of Korea

BACKGROUND: Clinician's prediction can detect things that cannot be objectively measured by test results. In fact, clinician's prediction and actual survival has a significant correlation. No studies have been conducted about the effects of team assessment to predict survival in terminal cancer patients. The aim of this study was to verify the validity of the clinical prediction between individual and team approach in predicting the survival of terminal cancer patients.

METHODS: This is a prospective observational study with hospice inpatients selected 137 people. Four doctors predicted each patients' survival. We obtain an mean value of 4 doctor's survival time. Correlation between survival and clinical expectancy was analyzed using Spearman's correlation. And we analyzed the degree of match of the evaluator by Cohen's Kappa and Intra-class correlation.

RESULTS: Clinician's prediction was correlated with the actual survival time. Team assessment was meant in overall survival group. Prediction between doctors did not match each other. The patients in short survival time have significantly high level of LDH, CRP, TB and lower level of PPS score.

CONCLUSION: Team assessment can be a good way to reduce a deviation of the predicted between clinicians. This study is thought to provide important information on hospice care in that point of the first study analyzed the concordance of clinical staff to predict in life expectancy.

Treating cause or consequence

Susana Elizabeth Riesgo, Brenda Elizabeth Riesgo Escudero, Antonio Carpintero Campos, Nuria Tuset Mateu, M Dolores Garcia Moriano, Davinia Blanco Cañas, Elena Pintado Outumuro
Catalan Institute of Health

The patient is a 62 year-old woman, partially autonomous for usual daily activities, who lives with her husband, retired and her main caretaker.

No known drug allergies, with a history of hypertension(2013), flaccid paraplegia(2014) and multiple myeloma(2013). Treated with Rabeprazole 40mg/24hours, Paroxetine 20mg/24hours, Duloxetine 60mg/24hours, Quetiapine 25mg/12hours, Haloperidol 15drops (if needed), Dalteparin 2500UI/ml, Gabapentin 1500mg/24hours, Morphine Sulphate 80mg/24hours and Lenolidorm-DXM (from 2015). Follow-ups are done by the Pain Management Clinic.

Upon arrival she was found in regular general condition; BP 90/60mmHg; HR 114bpm; RR 20rpm; Basal Sat.O284%; Temp.37.3°C; GCS10/15. Respiratory auscultation: widespread stertors. The case is oriented as end-of-life period. Subcutaneous line is placed and Morphine Chloride 1% 0.5ml/4hours, Butylscopolamine 20mg/8hours and Haloperidol 5mg (if needed) were started. The rest of her usual medication is suspended

TREATMENT

It was decided to provide family support, maintaining Morphine Chloride1% 0.5ml/4 hours, Butylscopolamine 20mg/8hours and Haloperidol 5mg(if needed)

EVOLUTION

After 10 hours we return to the home for a follow-up, only to find the patient in good general condition, conscious and oriented. BP 110/60mmHg; HR 103bpm; Basal Sat.O294%; afebrile. No signs of neurological deficit or meningeal irritation. GCS15/15. Respiratory auscultation:few crackles. Case is oriented as "Suspected drug poisoning in polymedicated patient"

We talk to family and decide to withdraw subcutaneous medication and begin a phased drug withdrawal. After 15 days of follow-ups, the patient remained stable, with a decrease in pain intensity. We continued with the drug withdrawal adjusting the pain treatment in conjunction with the Pain Management Clinic

CONCLUSIONS

Being fragile patients with multiple pathologies, it would be prudent to control not only daily clinical signs and symptoms, but to assess whether these are products of the disease itself or correspond to side effects of the drugs. This way, we will prevent treating drug side effects rather than the actual condition itself

Porocarcinoma: More Than a Rare Disease

Joana Guerra Silva, Ana Franganito Sardo
Algarve - ACES Central I - USF Mirante

BACKGROUND AND AIM:

Porocarcinoma is a rare skin cancer involving the eccrine sweat glands. It has a high potential of local destruction, metastization and recurrence. The aim of this report is to show the challenge to the offer of proximal care in peripheral areas in these cases that requires a close vigilance in specialized tertiary care centers.

METHODS:

Case report.

RESULTS:

Male, 63 years old, Ukrainian, emigrated to Olhão in 1999. Two years later, erythema lesions appeared on the upper face of his left shoulder. Because he did not have a Family Doctor, he recurred to a Dermatologist 5 years later, when an agglomeration of the lesions was verified. He initiated follow up in Lisbon's IPO, where the lesion was totally removed and the diagnosis of porocarcinoma was made. 6 years later it relapsed with a gangliar metastasis on the left armpit. An incomplete gangliar emptying was made, followed by radiotherapy, without complete remission. The wound was too suppurative, needing of triweekly bandages. He was attributed to a Family Doctor, beginning proximity care in articulation with IPO. Motivated by the clinic's worsening, he began chemotherapy in Faro's Hospital, in straight articulation with IPO.

CONCLUSION:

This case represents multiple challenges for the Family Doctor, not only due to its rarity, but also due to the patient's socialcultural context: emigrant who does not know the functioning of the NHS, with a follow up of his disease 300km away from his residence area and who cannot work. Due to the need of frequent treatments and of renovation of his temporary incapacity certificate for work, he maintains contact with his Family Doctor, who has a key role in the enlightenment of his doubts. The need of these patients' attribution to a Family Doctor is remarkable, so that efficient proximity health care can be made.

Keywords: Porocarcinoma; Eccrine Sweat Glands; Primary Care

Background and Aim

Porocarcinoma is a rare skin cancer involving the eccrine sweat glands, mostly affecting people in their 5th – 8th decades of live. It has a high potential of local destruction, metastization and recurrence and, therefore, a bad prognosis. The aim of this report is to show the challenge to the offer of proximal care in peripheral areas in these cases that requires a close vigilance in specialized tertiary care centers.

Case Report

Identification:

- PO, ♂
- 63 years old
- Caucasian

Palliative Care Knowledge of the Health Care Workers at a Tertiary Hospital

Hasret Korkmaz¹, Yasemin Kılıç Öztürk¹, Kurtuluş Öngel²

¹Tepecik Education and Research Hospital, Clinic of Family Medicine, Izmir, Turkey

²Izmir Katip Celebi University, Faculty of Medicine, Department of Family Medicine, Izmir, Turkey

INTRODUCTION: Although palliative care is a new discipline, it has positioned itself quickly in the other areas of medicine. The development of palliative care in Turkey has gained a momentum in recent years. This study has been carried out to determine the knowledge of health staff who work in a tertiary health institution which has a palliative care clinic. In addition, this study aims to create an awareness about palliative care.

METHODOLOGY: The sample size of the study consists of 318 medical staff (46 specialist doctors, 62 non-specialised doctors, 142 midwives or nurses, 69 allied health staff). In the study, socio-demographic form and "the level of knowledge of health staff in palliative care scale which was developed by Nakazawa Y et al. was used.

FINDINGS: The average age of participants was 33.8 ± 7.789 , female majority; the mean duration of the working in the profession was reported as 9.6 ± 7.929 years. 89.9% of health staff claimed that they did not receive training in palliative care during their vocational training and 91.5% of them stated that they did not receive training in palliative care during their work life. 79.9% of health staff indicated that they did not work at a palliative care unit. 64.5% of them qualified their own palliative care knowledge status as medium and 61.2% of them scored their palliative care knowledge level as insufficient. The majority of the health employees pointed out that they did not attend any training on pain, gastrointestinal tract, respiratory diseases, psychology / psychiatry or communication during the last year.

RESULTS: In accordance with the results obtained in this study, to increase the awareness of palliative care, palliative care topic in the education curricula and in-service training programs has been proposed to have a broader place.

Dying at home; a possibility in a rural area

Mercedes De La Cruz Herrera, Estefania Andrada Gomez, Josep Vidal-Alaball, Lourdes Martinez Moyano, Rosa Farrés Creus, Gemma Arnau Perramon

EAP Artés, Gerència Territorial de la Catalunya Central. Institut Català de la Salut. Catalunya

Reason for consultation:

Right axillary mass

Current Illness:

90 years man, autonomous in activities of daily life, preserved cognitively. Past medical history of hypertension and dyslipidaemia. No toxic habits. Not known allergies. Good family support. Initial consultation for presenting a right painful axillary mass for the last month. The mass had progressively increased in size. He explained asthenia, weakness and weight loss of 4kg in 2 months. No other symptoms.

Examination:

Patient stable. Right axillary mass of 3 x 3 centimetres, single, hard, painful to palpation and well-defined. Rest of examination without apparent abnormalities.

Complementary Tests:

Complete blood count: normocytic-normochromic anaemia. LDH cholesterol increased. Negative tumour markers. Normal chest X-ray.

Clinical judgment:

Based on the autonomy, cognitive status and presenting symptoms of the patient and in context of an axillary adenopathy and toxic syndrome, it was recommended a referral to the early diagnosis unit for study.

Evolution:

The patient chose not to do any further studies, as the probable diagnosis was likely to be cancer. The patient expressed his desire to die at home. His family (wife, sons and daughter) support his decision. A year after, he peacefully died at his home under the care of an interdisciplinary team integrated by the primary care and palliative care teams.

CONCLUSIONS:

Home medical accompaniment in the final stage of life fosters that many patients with advanced chronic diseases and/or terminal illness could maintain a good quality of life in its usual environment, respecting the will to be cared in their family environment and in a dignified and comfortable manner.

Analysis of Inpatients in Family Medicine Palliative Care Unit

Yusuf Adnan Güçlü¹, Yasemin Kılıç Öztürk¹, Tefrik Tanju Yılmaz¹, Umut Gök Balcı¹, Nurdan Tekgül¹, Haluk Mergen¹, Kurtuluş Öngel²

¹Tepecik Training and Research Hospital, Department of Family Medicine, İzmir, Turkey

²İzmir Katip Çelebi University, Faculty of Medicine, Department of Family Medicine, İzmir, Turkey

AIM: Palliative care includes physical, psychological, social and spiritual supports to those patients with life threatening diseases and to their care givers, in order to improve their life qualities. The first palliative Care (P.C.) unit under the name of Family Medicine clinic was opened in June 2013 at Tepecik Education and Research hospital. Chronic patient care, support therapy to home care patients, pain palliation and nutritional support to cancer patients are some of the health services that our unit provide. Purpose of the study is to analysis the patients that followed-up for two years.

MATERIALS-METHODS: Age, gender, diagnosis and hospitalization period of the patients and records were analyzed retrospectively between June 2013-May2015.

FINDINGS: There was 889 hospitalizations. Bed fullness ratio was 55.14%. When repeated hospitalizations were excluded, 594 patients was found. Ages were between 17 and 101 (mean:61) and 240 (40.4%) male, 354 (59.6%) female. The diagnosis were; 37.4% (n:222) obesity, 23.2% (n:138) malignity, 16.3% (n:94) neurological deficiets, 9.6% (n:57) chronic renal deficiency, 7.4% (n:44) diabetes mellitus, 6.1% (n:36) other diseases. Mean hospitalization period was 12.96 days (min:1, max:187). 392 patient were transferred from other clinics; internal medicine 274 (63%), hemodialysis unit 79 (20.1%), anaesthesia unit 10 (2.6%), onchology+hematology unit 80 (38.4%), other units 38 (9.7%). The rest 497 hospitalization was made from out patient clinic and home care services. 209 patient was consulted; internal medicine 91 (43.5%), hemodialysis unit 80 (38.4%), anaesthesia unit 12 (5.7%), orthopedia 8 (3.8%), coronary intensive care unit 6 (2.9%), other units 12 (5.7%). 50 patients has died in the P.C.unit.

RESULTS: Most of the P.C. Unit patients were female, most of the patients were diagnosed as morbid obese, onchological and cerebro-vascular diseases.

A multi-disciplinary approach to a palliative care patient

Yusuf Adnan Güçlü¹, Yasemin Kılıç Öztürk¹, Kurtuluş Öngel²

¹Tepecik Training and Research Hospital, Department of Family Medicine, İzmir, Turkey

²İzmir Katip Çelebi University, Faculty of Medicine, Department of Family Medicine, İzmir, Turkey

AIM: Palliative care approach to a bedridden female patient with electrolyte imbalance due to impaired renal function and both lower limb circulatory disorders is presented.

CASE: A 48 old female patient suffering weakness and lack of oral intake was hospitalised because of wounds on feet and ion imbalance due to pre-renal acute renal failure. She had a past history of post-viral infection related childhood blindness, hypertension and spasticity with joint deformities. She became bedridden 3.5 years ago because of rheumatoid arthritis. On physical examination, cooperation and orientation was intact, she had pain; also cachectic appearance, scoliosis, spasticity of all extremities and multiple joint deformities, atrophied limbs, complete loss of vision in both eyes and severe infected wounds at the lower extremities. Patient was consulted with dietician, physiotherapists, social service, internal medicine, cardiology, cardiovascular surgery, orthopedics, infectious disease, plastic surgery. Hydration, parenteral nutrition support, wound care and physiotherapy was planned. During the daily follow-ups with blood tests renal functions got better and hyponatremia and hyperkalemia were treated. Ampicillin sulbactam three times a day were prescribed for the infected wounds. She had a deficit of 3000 ml during the intake output follow-ups. Biochemical findings and blood count were normal. Urinary wbc: +++, Erit: +. Blood hormonal levels were at normal range. GR - bacillus produced at tissue and wound culture. Brain CT was suspicious about meningioma or subdural hematoma. Appropriate antibiotic therapy was continued. After the patient's fluid deficit has been corrected, oral nutrition was provided and the patient was externed according to her request.

CONCLUSION: In this case, interdisciplinary approach; one of the most important features of palliative care was used during the evaluation and management of the bedridden patient with severe problems.

Approach to a Brugada, Wolf Parkinson White Syndrome Morbid Obesity Patient in a Palliative Care Unit

Yusuf Adnan Güçlü¹, Balcı Umut Gök¹, Yasemin Kılıç Öztürk¹, Kurtuluş Öngel²

¹Tepecik Training and Research Hospital, Department of Family Medicine, İzmir, Turkey

²İzmir Katip Çelebi University, Faculty of Medicine, Department of Family Medicine, İzmir, Turkey

AIM: The main features of the Brugada syndrome are arrhythmias, palpitations, fainting and sudden death. Brugada syndrome must be considered if there is ECG changes from type 2-3 to type-1 for ajmaline test. In this case; it was aimed to present the approaches to a morbid obese young female patient with cardiac arrhythmia. CASE: Previously overweight patient, had previously been referred to a dietician and has lost weight for many times. She gained almost 40 kg. within 3-4 years. In November 2014; she had an operation due to Wolf-Parkinson-White (WPW) syndrome. She was admitted to obesity inpatient service for weight loss. She had ankylosing spondylitis, WPW syndrome, brugada syndrome, with a smoking history. Her father dead from lung cancer. In physical examination; both hemithorax were attending respiration equally. There were no crackles or rhonchi, no additional sound heart, murmur, abdominal comfortable, tenderness, rebound and no defense. Peripheral pulses were open. Patient were followed in the clinic. Routine blood tests were; all normal. She had ECHO and ablation with electrophysiological studies seven months ago. Preexcitation not occurred again. Ajmal patient's test was positively identified as a result of Brugada. Patient and her family were informed about the situation; she was

discharged. Patient had a medical board report with the diagnose of supraventricular tachycardia, WPW syndrome and ventricular laid Brugada syndrome that does not interfere with work. According to the list of prohibited drugs in appropriate patients that insulin resistance, metformin 1000 mg 2x1 was started. Diet and an exercise program has been edited slightly.

RESULT: A multidisciplinary approach has been followed for this morbidly obese patient with Brugada and WPW syndrome.

case of guillain-barré syndrome with morbid obesity

Berna Erdoğan Mergen¹, Hande Ileri², Haluk Mergen²

¹Karabağlar Community Health Center

²Izmir Tepecik Training & Research Hospital

INTRODUCTION: Guillain-Barré Syndrome (GBS) is an acute, severe and fulminant polyradiculoneuropathy in autoimmune nature. Incidence is about 1-4 cases per 100000. An ascending paralysis starting from legs, weakness evolves over hours to few days. Low cranial nerves are affected also requiring airway maintenance. In 70% of cases, a prior infectious process 1-3 week ago with Campylobacter jejuni, HSV, CMV, Epstein-Barr virus and Mycoplasma pneumoniae.

CASE: Patient whom estimated weight was 250kg has and body mass index 53, has been admitted to hospital with weakness at legs, ataxia and fall with vomiting, nausea, diarrhea and lassitude four month ago. Preliminary, the patient has been taken in the Neurology Intensive Care Unit. IVIG is implemented 5 days to quadriparetic patient. By the way, pressure ulcer occurred in the back of patient. Paresis is relieved in the following days and second cure of IVIG is not thought. Quadriparetic relieved to 3/5 in upper extremities and 2/5 in lower extremities. After, the patient is referred to our palliative clinic for physical therapy and pressure ulcer therapy. Laboratory results were as well: WBC:8500/L, Hb:11.8 g/dl, PLT:247000/L, glucose: 123 mg/dl, creatinin:0.7mg/dl, uric acid:7.4mg/dl, total cholesterol: 149mg/dl, triglyceride: 83 mg/dl, HDL:44mg/dl, LDL:88mg/dl, AST:33U/L, ALT:23U/L, ALP:52U/L, GGT:13U/L, LDH:306U/L, albumin:2.9g/dl, globulin:4g/dl, Na:134mmol/l, K:3.77mmol/l. Daily wound dressings applied and metformin 1000gr is started twice and IV furosemide therapy daily. Ciprofloxacin is started twice daily because the results of urinary test. In the 13rd day, cellulitis has begun in the

right leg. Oral antibiotherapy applied. After pressure ulcer is relieved, we thought to discharge the patient but her paresis was yet 2/5 in lower extremities.

CONCLUSION: Guillain-Barré is a rare syndrome but our case had also morbid obesity. Her weight couldn't be measured because she could not stand up.

Keywords: guillain-barré, morbid obesity, paresis

Home care patients: Suitable household living condition requirements

Gizem Limnili, Ülkü Bulut, Ceren Kenesarı, Nilgün Özçakar
dokuz eylül üniversitesi tıp fakültesi aile hekimliği ad

Background & AIM:

Home care service aims to increase the life quality of the patient who is recovering after a hospital or facility stay, or need additional support to remain safely at home and avoid unnecessary hospitalization and providing them living independently in their social environments and at their homes. Families and society play a key role in the security, care, support and treatment of the patients who need home care. Also home environment is important for these patients. The aim of this study is to determine home environment needs of patients who need home care.

METHOD:

This is a cross sectional study including home care patients who had been visited and examined by Dokuz Eylül University Medical Faculty, Department of Family Medicine. All patients were asked about their demographic data, their house and building was examined for proper use of the patient. Descriptive analysis, mean, median, standard derivation, chi-square is used for data evaluation. $p < 0.05$ was considered statistically significant.

RESULTS:

Totally 51 patients were included the study during home care visiting. Mean age was 66.78 ± 21.86 and 58.8% was female. 13.3% were living alone, 33.3% was married. 33.3% were could not read or write. 74.5% were using health devices; most used device was a crutch. The need of new devices was 35.3%. The 31.4% of the houses were not proper for use of wheelchair or walker. The most of the stairs of the building were not proper for patients to use also there was no elevator. Fortunately 52.9% was living on the first floor.

CONCLUSION:

The importance of home care is rising in last years. Home care patients need support to have high quality of life. They need medical and daily care but also more convenient house and buildings.

Understanding the experiences and quality of life issues of women with breast cancer

Ghufran Jassim

Family and Community Medicine, Royal College of Surgeons in Ireland- Bahrain, Bahrain

Palliative care is in its early stage of evolution in the Middle East and North Africa (MENA) region, and its practice encounters many challenges and barriers. Adaptation of guidelines should take into consideration the situation and unique needs in the targeted region to improve the standard of care to an internationally acceptable level. Most countries in the region are classified as category 2 in palliative care development which means that they have begun implementing various palliative care capacity-building activities but have no formal services. I have conducted a qualitative research to explore and understand the experiences and quality of life issues of women with breast cancer particularly those with a more cultural and religious basis. This is important to healthcare professionals in ensuring an individualised and sensitive approach to women with breast cancer. The results might also be applicable to migrant women who share the same cultural and religious backgrounds.

Prevalence of Urinary Tract Infections and Related Factors in Patients who Registered Home Health Care Unit

Rabia Dane Kocasaraç¹, Elif Erdoğan Cenik¹, Mahcube Çubukçu², Mustafa Kürşat Şahin³, Şükriye Bayrak Özdin¹

¹Department of Family Medicine, Faculty of Medicine, Ondokuz Mayıs University, Samsun, Turkey

²Department of Family Medicine, Samsun Education and Research Hospital, Samsun, Turkey

³Canik Community Health Center, Samsun, Turkey

AIM: Home Health Care Unit a unit provides health services for elderly, bedridden and individuals with chronic diseases at home along within the frame of the diagnosis, and treatments of the relevant experts. Therefore, it is intended to reduce the probable physical and emotional burden related to the patient that arise by commuting to the hospital, to improve the living standard by reducing the risk of hospital infection. In this study, we investigated urinary tract infection frequency and related factors in patients who get medical support in home health care unit.

METHODS: The following study was performed on 70 patients who admitted to Samsun Education and Research Hospital Home Health Care Unit 1 to 28 February 2014. In the analysis, frequency and percentage from descriptive criteria were used.

RESULTS: There were 46 (66%) female and 24 (34%) male patients. Patients average age was 68 (range: 14-80). Three of the five patients were bedridden. The most common disease was Alzheimer (n=18,% 25,7). The other diagnosis were cerebrovascular disease, hypertension, diabetes. Fourty two patients used diaper, three patient used foley catheter, six patient used condom catheter. Urinary tract infection was detected in 12 patients. Urinary tract infection frequency was 34%. The most frequent pathogens were E. Coli (52%) in urinary culture. We were ordered a prescription to patient who had pathogens in urinary culture. Older than 50 age, women, foley or condom catheter and immobilization was detected to urinary tract infections related factors.

CONCLUSION: In recent years home health care units became even more important after the gradual increase in the elderly population and chronic disease. Urinary tract infections were common in bedridden patients.

Providers should gave education about hygien to patients and their relatives. Urinary tract infection increased mortality in bedridden patient, so infection must be treated.

Homeless Patient with the Diagnosis of Scalded Skin Syndrome, Acute Renal Failure and Cardiac Failure- Case Report

Yusuf Adnan Güçlü¹, Kurtuluş Öngel²

¹İzmir Tepecik Education and Research Hospital

²İzmir Katip Celebi University; Faculty of Medicine, Department of Family Medicine

INTRODUCTION:

Staphylococcal scalded skin syndrome is an infectious disease which may develop due to a bacterial toxin. Fluid loss that occurs with the explosion of these blisters may cause to the corruption of the patient's blood chemistry and dehydration. The infection may be disseminated and cause a life threatening situation(sepsis) even during an effective treatment. It is aimed to highlight the approach to such a patient in this case report.

CASE:

A 72-year-old homeless male patient who had a diffuse pruritus and was treated with the diagnosis of ARF(acute renal failure) and HF (heart failure) at the palliative care service.

He was cooperated and the general state was medium. Widespread desquamation, scars and lesions due to pruritus were present on the body and face.

Laboratory findings were wbc:25000; crp:274,2; Urea:143; cre:1,6; alt:73; Procalcitonin:3.7.

Gram – bacillus at urine culture and gram+ coccus at blood culture were found.

With the diagnosis of scabies and xerosis permethrin treatment was used. Skin lesions disappeared after the treatment. More after bulleus lesions occurred during the follow-up and diagnosed as staphylococcal scalded skin. Ampicillin+ sulbactam treatment was given.

Supraventricular tachycardia occurred and Digoxin, Spironolactone, beta blocker treatment were started according to the cardiologic consultation. Skin lesions aggravated during the follow up and hypotension, dyspnea occurred and so he was transferred to intensive care unit. Respiratory arrest occurred during the intensive service follow ups and he became excitus.

CONCLUSION:

Homeless patients who are in need of care constitute a major problem at inpatient clinics because of the lack of caregivers. Despite the positive studies done for such conditions in our country there are still shortcomings about institutional care of homeless patients.

Keywords: Scalded Skin Syndrome, palliative, homeless.

Prevalence of the patterns of alcohol consumption in the spanish primary care

Victor Lopez Marina¹, David Rodriguez Vargas¹, Gregorio Pizarro Romero², Mireia Valle Calvet², Nuria Montella Jordana³, Rosa Alcolea Garcia⁴, Teresa Rama Martinez⁵

¹Primary Care Center of Piera. Catalanian Health Institute. Barcelona. Spain

²Primary Care Center of Badalona 6-Llefià. Catalanian Health Institute. Barcelona. Spain

³Teaching Unit of Family Medicine North Metropolitan. Catalanian Health Institute. Barcelona. Spain

⁴Primary Care Center of Besos. Catalanian Health Institute. Barcelona. Spain

⁵Primary Care Center of Masnou-Alella. Catalanian Health Institute. Barcelona. Spain

- **BACKGROUND AND AIMS:** Alcohol is the second cause of disability in the European Union countries behind the tobacco, assuming the 15-20% of the consultations performed in primary care. Given the scale of the problem, especially in men, we design this study to analyze the prevalence of the different patterns of alcohol consumption in men in the spanish primary care.

- **METHODS:** Design: a descriptive transversal multicenter study. Emplacement: 4 primary care centers. Subjects: 493 men > 17 years old, systematically selected during the recruitment period. Variables and **METHODOLOGY:** age, alcohol consumption in weekly units (standard unit drink [SUD]) and classification (abstinence, moderate and risk drinking). If risk drinking (≥ 28 SUD/week, ≥ 6 SUD/drinking opportunity), the AUDIT test is passed: if > 8 is classified as harmful use and/or dependence, and is passed the MALT-S test and ICD-10 scale (is diagnosed dependence if > 3 and > 2 , respectively). Statistics: mean (X), standard deviation (SD), percentages, CI [95%], Kappa index.

- **RESULTS:** Age (X \pm SD)=55.4 \pm 17.2 years old, 66.7% of the patients consume alcohol (average consumption of 16 \pm 12.5 SUD/week) and 17.8% are risk drinkers (CI [95%]=14.5-21.2%). 10.3% (CI [95%]=7.6-13%) have AUDIT > 8 , 9.3% (CI [95%]=6.8-11.9%) have MALT-S > 3 , 7.1% (CI [95%]=5-9.3%) have ICD-10 > 2 (figure 1). Of the risk drinkers, 66.2% (CI [95%]=56-77%) have AUDIT > 8 , of which 88.5% (CI [95%]=79.8-97.1%) are dependent by MALT-S and 67.3% (CI [95%]=54.5-80%) by ICD-10. Kappa index between MALT-S and ICD-10 is 0.423 (moderate concordance).

- **CONCLUSIONS:** Prevalence of the patterns of alcohol consumption obtained is consistent with other studies.

Moderate concordance between MALT-S and ICD-10 to diagnose alcohol dependence for overdiagnosis of MALT-S.

Missed Opportunities: Intimate Partner Violence Among Men and Women in a Primary Care Center

Yesim Incecik¹, Hatice Kurdak², Nafiz Bozdemir²

¹Başkent University, Department Of Family Medicine, Seyhan / Adana

²Department of Family Medicine, Cukurova University, Adana, Turkey

BACKGROUND & AIM: Intimate partner violence (IPV) is experienced by both genders in different frequencies and varieties. However, there are some barriers in verbalizing and recognizing it. For people experiencing IPV, health care visits represent valuable opportunities. This study aims to determine the effect of screening to identify IPV among men and women in a primary care practice.

METHODS: The study was conducted in two arms. In the prospective arm, 113 people were included who applied to outpatient clinic of Cukurova University during one month. Sociodemographic information was collected and IPV screening questionnaire was administered. The questionnaire was created to identify the perpetrators and the victims, using the RADAR-SA and the Abuse-Assessment-Screen by the researchers. Surveys were conducted face-to-face and confidentially during the patients' waiting time. In the retrospective arm, 109 medical files of the previous month that were compatible with the inclusion criteria were searched for IPV diagnosis.

RESULTS: Of the enrolled, 70,8% were women. The women's mean age was 43,8±13,0 and men's was 48,0±15,8. All the male participants and 26,2% of the women had their own income. Of the women 30,0% and of the men 45,5% had at least college education. The most prevalent IPV was emotional-IPV in women and men (50,0%, 24,2% respectively). The detailed information regarding the percentages of the participants' answers to the questions are given in table 1. Of the searched medical files 51,4% were women's and rate of IPV diagnosis was

8,9% among them. There was no IPV diagnosis in the men's medical files.

CONCLUSIONS: The found IPV rates among men and women were remarkably high, however; when IPV is not screened there may be quite a number of missed opportunities of diagnosis. Moreover screening IPV in both genders and perspectives may help to identify the multifaceted IPV in primary care.

Domestic Violence in Primary Care: what to expect

Sara Rigon¹, Sara Belinchon², Nina Monteiro³, Yusianmar Mariani⁴, Rosa Avino⁵, Elena Kuslova⁶, Elena Conde Valvis Fraga⁷

¹GP specialist, Bologna Italy

²GP specialist, Madrid, Spain

³GP Trainee, USF Porto Centro, Porto, Portugal

⁴GP trainee, Lethe's Health Center Unit in Ponte de Lima

⁵GP specialist, Venice Italy

⁶GP specialist, Ireland

⁷GP trainee, Madrid Spain

Background & AIM: Domestic violence is a global issue and can affect anyone or any household as it is not limited to any gender, religious, cultural or income group. Health care providers are well placed to engage in identification, support and referral of victims of domestic violence, especially GPs/FDs who are the first line of care and have a distinctive relationship with patients and families.

This poster aims to provide primary care professionals with essential knowledge on domestic violence to help colleagues identify symptoms and signs as well as support victims of such a peculiar form of violence.

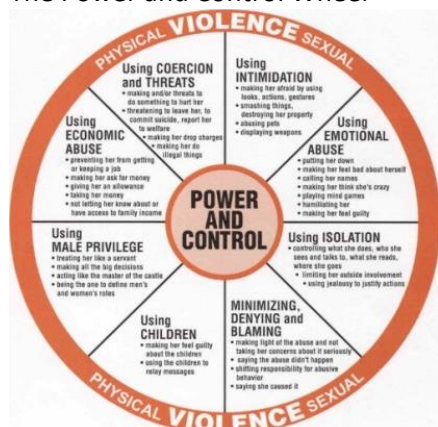

METHOD: through a review of most recent literature and guidelines on domestic violence this poster will display an overview of this epidemic phenomenon and its main unique features: circle of violence, use and abuse of power within personal relationships, isolation and acceptance of abuse, possible physical and emotional presentations and consequences on children.

CONCLUSION: education of GPs/FDs as well as, other professional health providers on this specific form of violence is the first step to an effective management and prevention of domestic violence.

RESULTS: this poster should arise awareness and inform colleagues on domestic violence. Most important, it should offer a evidence based overview as well as recommendations to assist colleagues willing to help potential victims.

Prevalence of the treatment of alcohol and other drugs users classified as moderate and severe by SAMU/DF

Ubirajara José Picanço De Miranda Junior, Isaac Sanglard Borel Ferraz, Ana Luiza Ataíde Moraes, Bruno De Souza Faria, Maria Cecília Dias Trindade

Escola Superior de Ciências da Saúde - ESCS - Federal District - Brazil

Background and AIM: the Federal District Mobile Answering Urgency Service (SAMU/DF) treats the population in urgent situations according the doctrinal principles of Brazilian health system (SUS): universality, equity, integrality. In this project the focus was the treatment of alcohol and other drugs (AD) users by SAMU-DF, emphasizing the principal demanded complaint and your classification. The project was executed by 4th grade students of medicine course from Escola Superior de Ciências da Saúde (ESCS) of Federal District-Brazil. The objective of this study is analyze the prevalence of treatment of alcohol and other drugs classified as moderate and severe by the central regulation of SAMU/DF. METHODS: exploratory study, executed from secondary data bank from SAMU/DF, covering 26.004 solicitation of medical care during the month of December 2013. 3% of those phone calls requested by alcohol and other drugs users was classified as moderate and severe by the regulator physician from SAMU/DF, corresponding to 740 phone calls. RESULTS: the highest demand of medical care was observed in male group between 18 and 59 years old, corresponding to 74,43%. From that, 79,45% was classified as moderate and 20,55% as severe. Abuse and intoxication by alcohol was the major diagnosis indicated by the medical relation, followed by abuse of other drugs, alcoholic coma and unconsciousness. The locations that realize the highest number of phone calls was in the southwest region of Federal District. CONCLUSION: the prevalence founded in this study was related mostly by intoxication and abusive use of alcohol and other drugs, alcoholic coma, convulsion and unconsciousness. Was not possible connect those diagnosis with traffic accident attended by SAMU/DF. New studies are needed to research the interconnection of alcohol and other drugs use with accidents and external morbidity causes.

elevated liver enzymes adherence to use of herbal drug in type 2 diabetes mellitus patient

Emrah Boyacıoğlu¹, Aydoğan Aydoğdu², Ümit Aydoğan¹, Oktay Sarı¹

¹Department of Family Medicine, Gulhane Military Medical Faculty, Ankara, Turkey

²Department of Endocrinology, Gulhane Military Medical Faculty, Ankara, Turkey

INTRODUCTION

Individuals with type2 diabetes (DM) have a higher incidence of liver function test (LFT) abnormalities than individuals who do not have diabetes. The most common abnormality is elevated alanine aminotransferase(ALT). Any diabetic patient found to have a mild chronic elevation of ALT, or elevation of ALT ≤ 250 U/L for >6 months should have screening for treatable causes of chronic liver disease, particularly hepatitis B-C and hemochromatosis, which are found with increased incidence in DM.

Some herbs are considered to be toxic to the liver. Women seem to metabolize certain toxins more slowly than men do, so their livers are exposed to higher blood concentrations of harmful substances. As you age, your liver breaks down harmful substances more slowly.

CASE

No active complaints and follow-up of 3 years, 78 year-old woman with DM was in use of oral antidiabetic. In the outpatient clinic examination elevated LFT and hyperglycemia (Table 1) were determined. The patient was

hospitalized for further examination and treatment of glycemia regulation. Acidosis was not determined. In the urine, ketones were not detected. Intensive insulin treatment was started for blood glucose control. Medical history: She had hypertension and DM. She was taking olmesartan+hydrochlorothiazide, carvedilol and metformin(1g/day). It was learned that patient was taking herbals for 2 weeks for the treatment of DM. Retinopathy and microalbuminuria weren't detected. Left-ventricular ejection fraction was found 60% after echocardiography. Abdominal ultrasonography revealed no abnormality except grade1 hepatosteatosis. After excluding other reasons lead to elevated LFT the conclusion that the herbal drug used the patient elevated LFT.

CONCLUSION

The fact that herbs are natural preparations from plants doesn't necessarily mean they are safe. It has been documented for centuries that some plant substances are toxic to the liver. For this reason while taking the medical history herbal drug usage must be questioned.

Keywords: herbal drug, elevated liver enzymes, type2 diabetes mellitus

Domestic violence among women and girls in Munshaat Sultan, Egypt

Hala Mohamed Elmoselhi Shaheen, [Nagwa Nashat Hegazy](#)

Department of family medicine; Faculty of medicine, Menofia university

BACKGROUND: Violence against women and girls is one of the most systemic and widespread violations of human rights worldwide. One-third of Egyptian women have been physically abused by their husbands/ father, according to EDHS 2005. Nearly 39% of women and girls think that a husband and father is justified in hitting or beating his wife/ daughter under certain circumstances

OBJECTIVES: The main objective of this study was to assess the different types of violence, explore the reasons behind this high percent of violence in Egypt and the roots of silence toward reporting.

METHODS: Females were recruited from the family health center clinic, Munshatt sultan village, using a convenient sampling technique. Qualitative approach was used to gain an in-depth knowledge of the issues. Two types of focused groups were organized, one for married women and the other for young girls. All interviews were facilitated by moderator and an observer, and followed a pre-tested questioning route. They were audio-taped, transcribed verbatim, and were then analyzed for thematic contents by the standard content analysis framework. Thematic content analysis

RESULTS: Two major themes were identified regarding the type of violence: physical and emotional violence. Difficulties in reporting for violence were different according to the age group where married women reasons were grouped in three main categories: cultural, personal and the presence of children. On the other hand girl's explanations were grouped into two main themes; financial and fear.

CONCLUSION: A major part of the domestic violence is related to the community where the thoughts of female inequity are still prevailing

Keywords: Domestic violence, Emotional abuse, inequity

Misconceptions of family doctors and family about the profile of addicts: case study

Marijana Aleksandar Pesic, Estera Dusan Vidakovic
Institute for Students Health, Belgrade, Serbia

BACKGROUND:

Evidence-based and on the basis of the traditional understanding of the addicts are characterized as people of lower socioeconomic and educational status.

AIM:

Demonstrate through two case profiles addicts who deviate from the expected, the importance of improving the skills of recognition addicts and their needs, in order to provide care, treatment and secondary prevention.

METHOD: Case study

RESULTS:

CASE 1: Female patient J.P., 23 year old, came to be referred for therapy for a HCV infection, a doctor wasn't her chosen. In order to build patient's trust the doctor had mentioned that the usual way of transmitting the HCV is injecting drugs, but even doctors have prejudices. The Patient's story: excellent student of mathematics, functional family. She had used drugs with her boyfriend in her room while studying. Her mother didn't disturb the children while they were studying. Happy, because they're at home. One day, J.P. decided to treat. Neither the parents nor the doctors have not thought that there is a problem with excellent student.

CASE 2: Male patient J.Dj., 20 years old, accompanied by his mother, comes by referral to the Institute of Mental Health, to a specialist who deals with pathological gambling. He had recognized the problem himself and decided to treat. Mother stated that no one doubted, because he is an excellent student. Finances were not an issue as he is a student of IT and he used his knowledge and skills to win.

CONCLUSIONS:

Addictions are becoming increasingly important public health problem. Raises the question of prevention, early detection (recognition), care, treatment and secondary prevention. It is necessary to improve the skills of listening and research needs of patients by family doctors.

Bronchial asthma and a strong need for family psychoeducation in family medicine

Maija Kozlovskā¹, Liga Kozlovskā¹, Sandra Gintere², Sandra Puce², Gunta Ticmane¹, Ruta Vintere²

¹The Rural Family Doctors' Association of Latvia

²The Riga Stradin's University

Introduction. A connection between asthma and emotional factors is determined. [Maimonides 1990, Alexander 1940, Dunbar 1948] The transformation of these people's lives involves their families. (Scott et al., 2007; Fernandes et al., 2010; Thomas et al., 2011; Di Marco et al., 2011).

Methods. The epidemiological study was made since 2014, May [ongoing] in Latvia in a family physician practice of 1400 patients, evaluating psychological aspects and need for familial psychoeducation for pediatric patients with bronchial asthma in the age of 1-18, involving data, literature analyses.

Results. The control of asthma correlates with anxiety state ($r=0.554$; $p\leq 0.001$) and trait ($r=0.357$; $p=0.000$), as well as anger ($r=0.221$; $p=0.016$). [Fernandez, 2012] Since 2014, May till, 2015 March, 75 young patients with asthma were identified, whereof 92 % percent were having familial lifestyle problems, that worsened the disease, like mold, animals, excessive air drought/humidity, allergens, and familial smoking. 88% of pediatric patients were passive smokers due to smoking of at least one of family member. Smoking mostly was outside room and correlates with asthma cases. 14% involved more than one smoker in family, aside from the pediatric patient, which correlates with the severity of child's asthma. 70% of smoking parents did not want to start hormonal treatment, and did not want to quit smoking even after an hour long explaining of the importance and meaning of asthma control.

Conclusions. There is a strong need for familial psychoeducation for pediatric patients. Attention from higher institutions must be paid to child abuse concerning passive smoking and development of such chronic condition as bronchial asthma.

Keywords: child abuse, smoking, bronchial asthma

The angry patient: the role of mindfulness

Sara Isabel Andrade, Cristina Maria Bastos, Ana Rita Maria

Family Health Center Conde de Oeiras, Regional Health Administration of Lisbon and Tejo Value, Lisbon, Portugal

BACKGROUND:

Over the last years, several studies have examined patient aggression toward healthcare professionals including primary care physicians. Many studies reported high rates of maltreatment by patients. About 15 percent of patient-physician encounters are rated as "difficult" by the physician involved. In this context, patient characteristics, physician factors and situational issues all contribute to difficult clinical interactions.

Case description/AIM:

A 50 year-old caucasian male with no significant past medical history had a verbally aggressive behavior and physically intimidated the doctor because he refused to write a medical report. What approach would be most helpful to the patient? With this case report we want to highlight the role of mindful practice in the difficult encounter.

METHODS:

A search for articles published in the last twenty years in Cochrane Library and in Pubmed was performed using the MeSH terms "physician patient relationship", "aggression" and "mindfulness". Additional potentially relevant publications were identified by checking references of included studies.

RESULTS:

The mindful practitioner is present in everyday experience, in all of its manifestations, recognize its own errors and engage in more patient-centered communication. In addition, the mindful practice may decrease the number and intensity of difficult encounters and should be considered a characteristic of good clinical practices.

CONCLUSIONS:

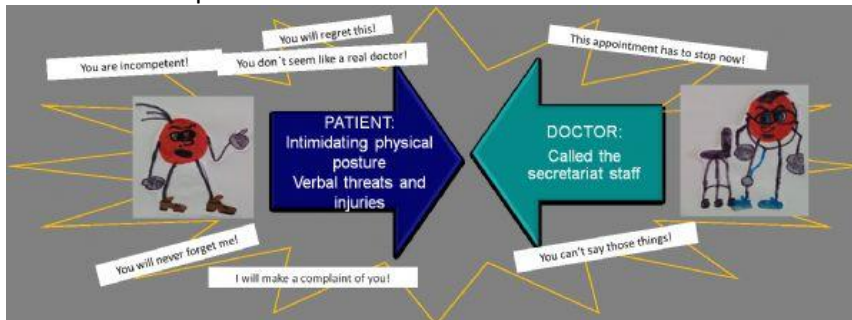

There will always be difficult relationships in the clinical practice. It's important to learn how to manage these situations so that we can turn them into productive interactions. Becoming more aware of your own physical, mental and emotional processes may contribute to a successful patient-physician relationship.

Keywords: Keywords (MeSH terms): physician patient relationship, aggression and mindfulness.

Training in Gender Violence (GBV) is essential to raise awareness among professionals to detect and care for victims with a comprehensive approach.

OBJECTIVES:

Evaluate the changes in knowledge, skills and attitudes in health professionals who participated in a 18 hours training workshop in GV, with a previously established methodology and content. Opinion on methods, content, teaching quality and applicability to practice was evaluated.

METHODOLOGY:

Pre-workshop (online) and post-workshop questionnaire (physical) and 6 months questionnaire to assess the transfer into practice (Emailing the participants)

Study: Cross Descriptive.

Sample: 23 students attending the workshop VG

RESULTS:

60% of the 23 students were nurses and 30% physicians. 77% were professionals in training (residents). 77% were women and the age average 31.45 years. 87% hadn't received any prior course. When they were asked about the motivation to attend the course, most of them answer that they need training for the detection and management of cases. Questions on knowledge, attitudes, level of safety, resistances, perception of their role in this situation, previous experiences, were some of the dimensions explored.

The perception of safety in handling the case increased after the training activity (4.8 to 7.5)

The overall rating of the workshop has been positive, all students felt that the course has been adapted to their needs and their objectives have been achieved. They were asked to make an assessment of the different methodology and role playing method was more valued.

6 months after, the post-workshop survey shows that the evaluations is the same, with a slight decrease, and relate perceived usefulness and transfer into practice, where they had the opportunity.

CONCLUSIONS:

We believe that training in GV is the first step in changing attitudes and train health professionals in managing the problem. It is necessary to get motivate professionals and adapt content and methodology and assess the impact of it

Reliability and Validity of The Turkish Version of "The Severity of Violence Against Women Scale"

Canan Tuz, Mehmet Ergun Öksüz

Başkent University, Family Medicine Department

Violence against women is a complex worldwide problem not only in developing countries. Information about prevalence, associated factors and consequences of violence against women in Turkey is scarce. Even if there are some questionnaires to identify the tragedy in domestic field, very little is known about the intimate partner violence at universities.

The purpose of this study is to validity and reliability of The Severity of Violence Against Women Scale (SVAW) in Turkish population. SVAW is part of Measuring Intimate Partner Violence Victimization and Perpetration which is demonstrated by Marshall LL in 1992 and is an assesment tool in Center of Diseases Control and Prevention Center(CDC).

170 female college students were included in the study in which SVAW was examined for construct validity and reliability. This study was conducted during March-April 2015 in Başkent University.

Factor analysis was performed to assess the underlying domain structure of the questionnaire and to evaluate validity, the degree to which each item is related to the hypothesized domain with which it is associated. The reliability was calculated by using Cronbach's alpha formula.

Based on clinical interpretations of a principal-components analysis, 9-domain structure was identified which included of Principle Component Analysis and Varimax rotation (Eigen Value ≥ 0.7). Scale with this nine domains expanded variance was %88.1. Item loadings were found between 0.443-0.884. The value of the scale was in level high reliability (Cronbach: 0.979). Subdomains were similar to the original survey as symbolic violence, threats of mild violence, threats of moderate violence, threats of serious violence, mild violence, minor violence, moderate violence, serious violence and sexual violence.

SVAW, a 46 item based scale, has been developed as a brief, multidimensional self-report instrument for assessing the severity of violence against women. The Turkish version of SVAW is psychometrically sound, easy to administer, reliable and valid.

Which trauma is so dangerous?

Betül Battaloğlu Inanç

Department of Family Medicine, Muğla Sıtkı Koçman University, Muğla, Turkey.

Background & AIM: In all societies and in each culture, past and present, violence has played a role in shaping our sociocultural evolution in Turkey. The analysis of the frequency of childhood traumatic events in midwifery students and the compare correlation with depression and anxiety traumatic events were aimed in this study.

METHODS: Self-report instrument was designed to evaluate abuse and neglect experiences of childhood and adolescence in the University of Mardin Artuklu Health School the Midwifery students. Childhood and adolescence lives evaluated childhood trauma questionnaire (CTQ). Depression and anxiety relates evaluated with the Beck Depression Inventory and the Beck Anxiety Inventory.

RESULTS: The students mean age were 21.4 ± 1.9 , CTQ points average was 35.8 ± 9.1 , Beck depression inventory average points was 13.7 ± 10.4 , Beck Anxiety Inventory average points was 19.8 ± 12.7 . The CTQ total points was significantly associated between depression and anxiety. ($p < 0,001$).

CONCLUSIONS: A growing body of evidence suggests that the developing brain organizes in response to the pattern, intensity and nature of sensory perceptual and affective experience of events during childhood. Threat activates the brain's stress-response neurobiology. This activation, in turn, can affect the development of the brain. Indeed, the developing brain is exquisitely sensitive to stress. These results could indicate that previously experienced emotional and physical traumas has more relationship to anxiety and depression symptoms and this pathological position which is an expected result of the trauma.

Sociodemographic Characteristics of Patients Applying to Alcohol and Substance Abuse Treatment and Education Center (AMATEM) in Konya

Fatma Selek Demirel¹, Başak Demirel², Fatma Goksin Cihan³, Şule Erayman Demirbaş¹, Yasemin Alagöz¹

¹Family Medicine Clinic, Konya Training and Research Hospital, Konya, Turkey

²Department of Psychiatry, Konya Training and Research Hospital, Konya, Turkey

³Department of Family Medicine, Necmettin Erbakan University, Meram Medical Faculty, Konya, Turkey

AIM: The aim of this study was to analyze the sociodemographic characteristics of the patients who had visited the Alcohol and Substance Abuse Treatment and Education Center (AMATEM) at Konya Training and Research Hospital.

METHODS: In this descriptive study, a socio-demographic data form was applied to 61 patients who had admitted to AMATEM from January 2015 to March 2015.

RESULTS: The mean age of the participants was 23.48±4.67. Of the participants, 88.5% (n: 54) were men, 23% (n:14) were married. All patients were smoking. Mean age for smoking initiation was 13.36±3.19 years old. Mean age for initiation of substance use was 16.59±4.05 years. 88,5% (n:54) participants had begun substance use in Konya city. The mostly used substance was marijuana [(55.7%) (n: 34)] and second was heroin [26.2% (n: 16)]. The rate of using multiple substances was 72.1% (n: 44). Fifty one percent of them had used their first substance when they were student (n: 31). The intravenous heroin users rate were 23% and 21.4% of them were sharing their injection equipments.

CONCLUSIONS: One fifth of patients using intravenous heroin were sharing drug injection equipments which can cause transmission of diseases like Hepatitis B and C, AIDS etc. with blood and body fluids. All of the participants were smoking. Average age for initiation of smoking was very low. Families and health care professionals should be aware of the fact that smoking leads to substance abuse. This underlines the importance of prevention of smoking as it will reduce the substance abuse also.

Keywords: substance abuse, smoking, heroin

Aggressive patients, frequency and causes in family medicine

Amra Zalihic¹, Gordana Pivic², Mirela Mabic³, Adna Zalihic Pita⁴, Maja Pivic⁵

¹Health Care Center Mostar, Hrvatskih branitelja of A

²Health Care Center Mostar, Hrvatskih branitelja of B

³Universiti of Economy Mostar, Matice Hrvatske bb, of C

⁴Health Care Center Mostar, Hrvatskih branitelja of D

⁵Health Care Center Mostar, Hrvatskih branitelja of E

Aggressive patients are current topic in every country. Every day we have more aggressive patients in our office. The aim of our study is to examine frequency of aggress and possible causes of that.

We have divided 80 made questioners to medical workers (doctors and nurses). For analyses there were valid 73. Study is made in Health Care Center Mostar, B&H.

There were 32,9% doctors, of what 11% specialists, 6,8% primaries, 12,3% GP and 2,7 residences. Our institution is women's organization (88% women). The most were people age 25-30 and 51-55 (21,9%), and there were 27,4% workers with >25 years experiences.

78,1% participants have had any shape of aggression, in 47,4% once a month. 87,5% doctors and 73,5% nurses said that experienced aggressive attack. The most of them have experienced a quarrel (63%), insults (54,8%), threats (38,4%), physical attack (2,7%) and unjustifiably snitching (58,9%). As causes, subjects mentioned a long of waiting (80,7%), the health care system as a whole (75,4%), the amount of time devoted to patient (57,9%), the scope of rights of the insured (57,9%), dissatisfaction with the quality of medical services (43,9%) and physician relationship to the patient (35,1%).

CONCLUSION: the most participants said that aggressive patients are more often (58,9%), 32,9% think that

situation is the same, and only 8,2% think that is less than earlier. Reason for these results could be numerous number of young people who have not had the chance to experience aggression. The most participants mean that reason of aggression is length of waiting. Why? We use appointments, which patients do not respect, and on this way they make crowd and physician don't have enough time. We think that our health system must support family physicians for better satisfaction of patients and physicians what could result in the reduction of aggression.

Exposure To Domestic Violence Among Women Aged 15 And Older

Edibe Pirincci¹, Evrim Celebi², Ayse Birsen Durmus³

¹Firat University, School of Medicine, Department of Public Health, Elazig, TURKEY

²Firat University, School of Nursing, Elazig, TURKEY

³Firat University, College of Health Services, Elazig, TURKEY

BACKGROUND & AIM: This study aims to determine exposure to domestic violence among married women at 15 years of age and older.

METHOD: This study is descriptive and cross-sectional. It was conducted in the city of Elazig with 792 married women selected from those who visited primary healthcare centers using simple random sampling. In the field work, the authors contacted 760 women. The questionnaires were filled out during interviews in their homes. To evaluate the data collected, the author used the SPSS package program for statistical analysis. In comparisons, values of $p < 0.05$ were deemed to be statistically significant.

RESULTS: The average age of the participating females is 35.72 ± 10.84 years. Of the participant females, 47.4% were exposed to violence by their husbands at least once during their marriages, 20.8% experienced violence by their husbands at least once during pregnancy, and 36.1% were exposed to violence by their husbands in the last year. Of those who are illiterate, 65.5% experience violence by their husbands, while this rate is 26.2% among university graduates ($p < 0.001$). The rate of women being exposed to violence increases in direct proportion to their age ($p < 0.001$). The rate of women subjected to violence by their husbands decreases in inverse proportion to their husbands' level of education ($p < 0.001$). The rate of domestic violence is 52.1% among housewives, while this rate is 30.2% among working women ($p < 0.001$). Of those who are 19 or younger, 56.2% are exposed to violence, while 42.5% of women above 20 years age experience violence ($p < 0.0001$). The better the economic status, the lower the violence level gets ($p < 0.001$).

CONCLUSION: Exposure to domestic violence among married women living in the city of Elazig is remarkably high. The authors believe that necessary training and service should be provided at individual, familial and social levels to solve this problem.

Objetives:

To know what are the best training methods valued by students attending to an 18 hours training workshop in sexual and intimate partner violence (IPV), with a previously established content and methodology, and their perceived usefulness for clinical practice.

Methodology

A post-training presence questionnaire evaluated the opinion of the participants about the teaching methods to raise awareness among professionals, to enable them to detect and improve their ability to care for victims of IPV. The methods that have been used, where the main variable is their perceived usefulness for clinical practice and the changes in knowledge and attitudes of these students before and after the course, were tested as well.

Study: Cross-Sectional Descriptive

Sample: 23 health professionals(residentsand staff) attending the workshop.

Results

23 students (77% women):60% nurses, 30% physicians. 77% learners. Average age 31,45 years. 87% hadn't received previously any course. The best valued method was role playing, representing dramatizations of actual cases in which learners acted as professionals in their consultation and the role of the patient was represented by a trained professional, using standardized patient. Others highly valued were the presentation and analysis of clinical cases, teachers' experiences and finally the theoretical presentations

Conclusions

We think that training in IPV is the first step in changing attitudes and training health professionals in handling this problem.The learners believe, that the most effective methods are those that place them facing the problem in a similar scenario that they will address in their practice. The role play let them express their feelings, develop questions and doubts in a playful and very helpful contexts that it doesn't make them feel as pressured or judged, as in others. Other highly valued were the presentation and analysis of clinical cases. This method provides practical tools with a realistic approach

Beware Of Home Accidents: Knitting Needle And Power Socket

Seval Yaprak¹, Özden Gökdemir¹, Ülkü Bulut³, Damla Güneş², Nilgün Özçakar¹

¹DOKUZ EYLUL UNIVERSITY / MEDICAL FACULTY / FAMILY MEDICINE DEPARTMENT

²DOKUZ EYLUL UNIVERSITY / MEDICAL FACULTY / PEDIATRICS DEPARTMENT

³BALCOVA PUBLIC HEALTH CARE CENTER / IZMIR

Introduction and AIM: Home accidents are serious community-health problems. Children aged between 0-14 years and elderly individuals are at risk of home accidents because of spending most of the daily time at home. Accidents require expenses and good deal of medical support and community-health policy. At child-health emergency daily practice, the incidence of new diagnosed trauma is 15% per year. In epidemiological studies it's reported that protection is needed more as accident risk of new-borns and children who started walking. Deadly and severe accidents are seen in children under 15 years old. Most common four children-traumas are drowning, poisoning, burning and falling. WHO(World Health Organisation) recommends preventing organizations, education and emergency healthcare. Meta-analysis shows that face-to-face parent conversation is more advantageous and effective in parental security-application.

CASE: A year-old boy brought to Dokuz Eylül University Pediatrics Emergency Service had a trembling electric-shock for about a minute after knitting needle insertion in power socket. In physical inspection, ABP:105/65mmHg HR:110/min RR:25/min BT:36,5°C O2sat %:100 GCS:15, general condition was good and he was conscious. Skin temperature, colour, general system inspection and electrocardiography were normal and there was no pathology. There was a lesion in line with right hand dorsal surface electric inlet orifice. Forensic report has been edited. This was his second house-accident; he also had a car-accident.

Discussion and RESULT: House accidents can be prevented. Unsafe environmental conditions and behaviours are important; a safe house-environment decreases expenditures and accidents. First home-accident factor is human and conscious/unconscious family members. Education and avoiding accidental behaviours are important in community health.

In protecting health-services, cognitive and behavioural approaches also prevent accidents. Determining risks and learning measures and safe behaviour are important behavioural-approaches. An effort for medical behaviour in protecting health in medical family practices contributes to community health.

Keywords: home accidents, children, community health

A Qualitative Inquiry on Domestic Violence of Working Children in the Industry Complex and Related Factors

Seyhan Hidiroglu¹, Melda Karavus¹, Ozlem Tanrioer², Turhan Salva³, Emel Lüleci¹, Bulent Herek⁴

¹Department of Public Health, Marmara University, Istanbul, Turkey

²Department of Family Medicine, Yeditepe University Faculty of Medicine, Istanbul, Turkey

³Department of Public Health, Maltepe University, Istanbul, Turkey

⁴Istanbul Public Health Directorate

OBJECTIVE: The aim of this study was to understand the factors related to domestic violence of the working children in the Industry Complex in a district of Istanbul.

METHODS:

This qualitative study was carried out with children working in the Industry Complex of Pendik. These children were working in this Complex under the guidance of Community for Helping the Working Children. Three focus group discussions were held to collect the data each composed of 10 children with one moderator and one reporter. The focus group discussions were held at the work places of these children and during their working hours.

RESULTS:

In our sample, all the children were males, aged between 14-18 years. The majority were the children of low income families who were not able to graduate from elementary school.

Almost all of the children admitted that they have been exposed to some kind of violence at home. The father was the main aggressor in most of the violence at home. Mothers were frequently victimized at home and the children could witness this. Children admitted that they became aggressive outside the home after they experienced violence at home. Some of the children believed that the reason for domestic violence was financial problems.

Conclusion

Although the children expect more understanding from their families as a solution; effective violence prevention programs including education of the families are needed to lower the rate of domestic violence. Immediate issues of economic survival for vulnerable families and children would also help.

Keywords: Domestic violence, working children, qualitative

A multidisciplinary vision of training methods in family violence

M Carmen Fernandez Alonso¹, Sonia Herrero Velazquez², Susana Sanchez Ramon², Raquel Gomez Bravo³, Thomas Beck⁴, Marion Winterholler⁵, Victoria Poon⁶, Yolanda Valpuesta Martin⁷, Hilde Hellberdn⁵, Marta Menendez Suarez⁸, Katrin Wolf⁵, Simon Cordon⁶, Ulrike Smrekar⁴

¹Regional Health Service of Castilla and Leon. Valladolid. Spain

²University Hospital Rio Hortega. Valladolid.Spain

³Spanish Society of Family Medicine and Community, Spain.

⁴Univ.-Klinik für Medizinische Psychologie. Innsbruck. Austria

⁵Signal.Berlin. Germany

⁶Haven,s Center. London.U.K

⁷Health Center of Peñafiel. Valladolid. Spain

⁸Clinical University Hospital of Valladolid. Spain.

OBJECTIVES:

To know what are the best training methods valued by professionals attending training in Intimate Partner Violence (IPV), and their perceived usefulness for clinical practice.

METHODOLOGY:

A questionnaire conducted by email or telephone evaluated the opinion of the participants about the teaching methods to raise awareness among professionals, to enable them to detect and improve their ability to care for victims and their perceived usefulness for clinical practice

Study: Cross-Sectional Descriptive

Sample: 42 professionals staff (doctors, nurses, social workwes, midwives, others) trained in IPV from different countries (13 U.K, 12 Germany, 10 Spain and 7 Austria). Most were female doctors from 26 to 60 years.

RESULTS: The most useful training method was role play (18). Working in small groups for analysis and discussion of cases, (10) sessions and case presentations (8), movie debate scenes, facts and figures, documentation and materials are the most useful aspects of the formation.

Suggestions: More discussion of cases (12) and practical tools, more training and in how to seek help. Improving communication skills. Working materials. Support for the management of emotions and supervision for complex cases

CONCLUSIONS: We believe that training in IPV is the first step in changing attitudes and qualifying health professionals in handling this problem. Learners want to learn about IPV to improve their competences and assist victims better and they consider more effective those methods that place them facing it in a similar scenario, like role play, letting them express feelings, develop questions and concerns, in a playful and helpful context without feeling pressured or judged. It also facilitates learning communication skills, awareness of one's ability to cope with this problem in their practice, and same in the analysis of real cases in small group.

We believe that it is necessary to have support groups or the possibility of supervision.

LOGOS

P-0822**reliability and validity of turkish version of sexual experiences survey- victimization version**

Canan Tuz, Mehmet Ergun Öksüz

Başkent University

Intimate partner violence is a major public health problem, reflected by both its prevalence and negative consequences. This survey is an assesment tool designed to measure victimization from and perpatrator of intimate partner violence in Center of Diseases Control and Prevention Center(CDC).

The purpose of this study is to validity and reliability of Sexual Experiences Survey- Victimization Version (SES) in Turkish population. SES is part of Measuring Intimate Partner Violence Victimization and Perpetration which is demonstrated by Koss, Gidycz&Wisniewski in 1987.

170 female college students were included in the study in which SES was examined for construct validity and reliability. This study was conducted during March-April 2015 in Başkent University.

Factor analysis was performed to assess the underlying domain structure of the questionnaire and to evaluate validity,the degree to which each item is related to the hypothesized domain with which it is associated. The reliability was calculated by using Cronbach's alpha formula.

Based on clinical interpretations of a principal-components analysis,2-domain structure was identified which included of Principle Component Analysis and Varimax rotation (Eigen Value ≥ 0.7).Scale with this two domains expained variance was %68. Item loadings were found between 0.443-0.884. The value of the scale was in level high reliability (Cronbach: 0.738).

SES is an 10-item scale that measures four types of sexual victimization, instrument for assessing the severity of violence against women. The Turkish version of SES is psychometrically realiable and valid.

P-0823**Health workers under threat of violence in Türkiye**

Fatih Özcan¹, Erdiñç Yavuz²

¹Kuruçeşme Family Healthcare Center, İzmit, Kocaeli, Türkiye

²1st Family Healthcare Center, Rize, Türkiye

Background& AIM: In this study, we aimed to draw attention to an important issue of our country's health care environment, verbal and physical violence against medical personnel by patients or their relatives, to examine the causes of these incidents and discuss solutions to prevent this violence.

METHOD: However, we evaluated the problem based on scarce studies performed by researchers, reports issued by Turkish Medical Association and other health professional organizations, television and newspaper interviews, articles and our own observation

RESULTS: Health media in Turkey claimed that TV series occasionally encouraged violence against healthcare personnel. Another issue we have encountered was TV-newspaper news blaming healthcare providers because of clinical complications. No actions were taken against these unfounded allegations. We also witnessed some politicians accusing doctors in front of large audiences. We observed that "113- White code" application launched to help violence victims of healtcare workers by Ministry of Health became nothing more than a free legal support. Eventually, this application did not help to prevent violence against health workers. In addition, existing legislation of the Ministry of Health does not contain any health administrative sanctions to those who use violence. A total of 23,120 cases of violence against health personnel have been reported for the last two years. The murder of two chest surgeons while working in their hospitals in the last 3 years and the murder of a medical school professor of thoracic surgery by the relatives of his patient in his university ten years ago were extremely dramatic.

CONCLUSIONS: Currently, the existence of violence against medical personnel in our country have an extremely negative impact on health workers. In fact the methods of preventing violence are well-known by both health workers and administrators. The only missing ingredient is the "will" of politicians and health managers to apply these methods.

Workplace Bullying - the role of family doctors

Luís Miguel Azeredo Lopes De Moura Paixão¹, Pedro Cardoso Ferreira², Ana Marta Garcia¹, Diogo Abreu¹, Maria João Trindade¹, Ângelo Costa³

¹UCSP Fernão de Magalhães, ACES Baixo Mondego, Coimbra, Portugal

²USF Dunas, ULS Matosinhos, Porto, Portugal

³USF Al-Gharb, ACES Central, Faro, Portugal

BACKGROUND & AIM:

Cases of workplace bullying are more and more frequent nowadays. In recent studies, approximately 5% of all workers have already been exposed. This exposure is linked to the development of several physical and psychological symptoms.

The aim of this review is to address the main clinical aspects of this situation and its proper orientation.

METHOD:

Bibliographic research of review articles and systematic review articles published in English, French and Portuguese, in the last 5 years, in the Medline / Pubmed database, using the MeSH term "Bullying", with the term "Workplace". 14 articles were found and 9 were selected for this review. We also selected a Portuguese PhD thesis on the subject.

RESULTS:

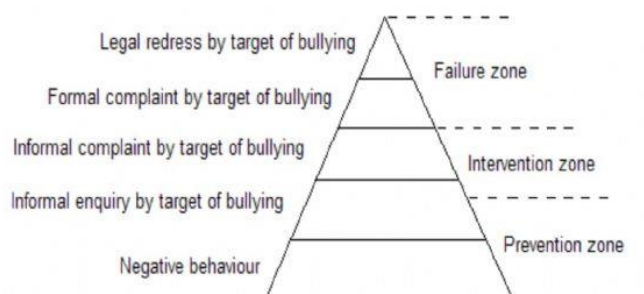

Workplace bullying refers to the situation where a person is submitted to physical or psychological violence, by one or several co-workers, repeatedly through time, not being able to defend itself. Various studies have linked this situation to the deterioration of mental health, increased levels of stress, various psychosomatic conditions, lessened self-confidence and increased sick-leave. As a family doctor, besides dealing with the physical and psychological symptoms, it is important to evaluate the affection of the family life, and the work-family imbalance, identifying possible victims of workplace bullying and giving the right legal and psychological support. One of the best methods found to control and stop workplace bullying involves cognitive rehearsal of responses to common bullying behaviors. Improved leadership (with anti-bullying policies) is also pointed as able to decrease the risk of bullying.

CONCLUSIONS:

This review pinpoints the physical and psychological repercussion that this situation may have in the health of the patient and its family, and reinforces the role that family doctors can have in this situation, providing a proper medical and legal support for these patients.

²Mardin State Hospital District Ömerli, Mardin

INTRODUCTION: Violence is any act or exercise of power (i.e. physical, verbal, emotional, economic, sexual) performed by an individual or community to exert power over other individuals or communities and to cause physical or psychological damage to them. Violence remains a serious and common social problem both for Turkey and the whole world. The aim of this study was to investigate the perceptions of patients admitted to hospital and their relatives into violence, which is a serious public health problem for all the communities in the whole world ranging between the most democratic communities and traditional societies.

MATERIALS-METHODS: The descriptive cross-sectional study was performed on the patients who were admitted to Dicle University Medical Faculty Hospitals between August 1, 2014 and February 1, 2015 and their relatives.. The questionnaire comprised included the Maudsley Violence Questionnaire (MVQ), which was used for assessing the tendency of the participants to violence.Data were analyzed using IBM SPSS 18.0 for Windows.

RESULTS: The 531 participants included 180 (33.9%) women and 351 (66.1%) men with a mean age of 32.5±9.6 years. Of the participants, 147 (27.7%) had eye-witnessed violence and (55.4%) 294 had been exposed to violence. Median tendency to violence was 7.74 (range, 0-32) and median approval of violence was 4.53 (range, 0-14). The men had higher scores in approval of violence and tendency to violence ($p<0.001$ for both). A significant correlation was found between exposure to physical violence and approval of violence ($p>0.036$). Low level of education ($p>0.001$), rural origin ($p>0.038$), and male gender established a significant correlation with tendency to violence and approval of violence

CONCLUSION: The rates of exposure to violence and eye-witnessing violence were remarkably high. A significant correlation was found between low level of education, rural origin, and male gender and tendency to violence and approval of violence.

Keywords: violence,approval of violence,tendency to violence

A regional learning collaborative to address the pubic health, public policy and primary care problem of chronic pain and opiate prescribing whilst providing enhanced learning oppourtunites for resident and attending physicians

Patrick S Mcfarlane

Family Medicine Center and Residency Program Eastern Maine Medical Center

In the New England Region of the United States opiate prescribing for issues of chronic pain have become a leading cause of morbidity and mortality after pharmaceutical industry driven initiatives to address pain as a fifth vital sign through national accreditation organizations requiring 1-10 perception of pain scales and the like. Opiate prescribing became a legendary problem in primary care practices as without regard to functionality, patients came to expect opiates to be prescribed ad infinitum, with pharmaceutical manufacturers promoting that there was no upper morophine equivalent limits and that addiction was not a comcomitant problem.

To address this a multimodal mulitdisciplinary effort in Maine was begun to address this problem and this talk is about a Professional Learning Community (PLC) model of addressing a public policy, public health and primary care driven problem with significant community impact.

The talk with highlight the Maine Chronic Pain Learning Collaborative (MCPLC) and effort of professional organizations in our region and a moderate sized residency program in Family Medicine that reduced long term opiate prescribing from a range

of 17-22% of patient panels to approximately 2%, and improved physician assessment of function, impact of medications, and provided early addiction intervention. We will briefly highlight suboxone and subutex treatment programs, and a multidisciplinary integrated approach to opiate prescribing, addiction and chronic pain.

Keywords: Addiction, Chronic pain, Opiates, multidisciplinary treatment

The influence of social and demographic factors on patient satisfaction with primary care

Rima Gaidamovic¹, Vytautas Kasiulevicius¹, Virginijus Sapoka¹, Ausra Deksnyte², Ramunas Aranauskas²

¹Clinic of internal medicine, oncology and family medicine, Vilnius University, Vilnius, Lithuania

²Psychiatric clinic, Vilnius University, Vilnius, Lithuania

Background & Aim. Patient's characteristics affect formation of his view on satisfaction and expectations of primary health care (PHC) services. One of the most important modern health care strategic objectives is to activate individuals, groups and organizations in the implementation of various health improvement programs, and to promote dialogue between health care providers and patients. The aim of our study was to identify and analyse the factors, that influence patient's satisfaction with PHC and find out whether it is possible to predict the patients' satisfaction with PHC in accordance with the basic socio-demographic factors and assess the tendencies of this impact.

Methods. The study surveyed 444 patients using self-addressed Patient satisfaction Questionnaire Short-Form (PSQ-18). Cronbach's alpha statistics were used for the validation of the questionnaire. The patients' data included age, gender, nationality, education and place of residence as well as the registration with the certain PHC service.

Results. The place of living, patient's age and PHC centre's reputation had significant influence on the patient's satisfaction with PHC. Patients from cities assessed almost all aspects of the service better, than the patients from regional centres and villages. Patients with basic and tertiary education level assessed PHC significantly better than patients with lower or upper secondary education. We founded only a tendency, that women evaluated PHC better than men. The oldest patients were satisfied with their PHC most, and the middle age patients were satisfied at least. Also patients, who attend more prestigious PHC centres, were satisfied with their health care more.

Conclusions. The patients' satisfaction was more dependent on the social (registration with the prestigious family health care centre, education) rather than on the demographic factors (gender and age). Further studies should include more PHC centres from different regions of country, also to include more factors characterizing patient's social status.

Keywords: Social and demographic factors, patient satisfaction, primary health care

Patients with type 2 diabetes (MD) complications and specialist consultations frequency of general practitioner

Mindaugas Paulius¹, Indrė Baužienė¹, Indrė Ličytė¹, Kazys Simanauskas¹, Eglė Simanauskienė²

¹Faculty of Medicine, Vilnius University, Lithuania

²Children's Hospital, Affiliate of Vilnius University Hospital Santariskiu Klinikos

Objective. Family physicians have increasingly faced with rapidly progressive complications of type 2 diabetes, so the question is, how often it should be promptly and how often our patient should be consulted a specialist. The aim - to assess how much a year occur with type 2 diabetes complications and how often professional advice for further treatment is needed.

Materials and Methods. A retrospective analysis of 46 Vilnius University Hospital Family Medicine Centre patients with type 2 diabetes was carried out. There were assessed the incidence of complications of this disease and how frequent the specialist was asked for consultation. A statistical analysis was done and the significance assessed by a X-square test. The statistical difference was considered spreads across if the p value was below 0.05.

Results. The most common complication of the disease - polyneuropathy – was diagnosed almost half of patients, retinopathy and nephropathy diagnosed with the rest of the test subjects. Almost one-third of the patients had two or more complications. HbA1c was a significant difference (p <0.05) in this index were higher in patients with polyneuropathy compared with non. Hunger glycemic index (p <0.05) higher in the group of patients with polyneuropathy. Because of the small subjects and the number of studies there were not able to compare indicators and non-diabetic patients with retinopathy or nephropathy groups. The patient should be referred to a

specialist (doctor endocrinologist), to assess the occurrence of diabetic complications, their progression and provided care plan once a year. Only 56.5% of the patients had been consulted a doctor endocrinologist, nephrologist consulted 6.5 % and ophthalmologist – 37 % of all patients per year, and a similar situation was during next year.

Conclusions. Complications of the disease is very common, however, the number of consultations should be higher.

Improving performance indicators in primary health care commissioning in Portugal

António Pereira¹, Sílvia Machaqueiro², Luís Velez Lapão³, Paulo Nogueira⁴, Matilde Rosa⁴, André Biscaia⁵

¹Unidade de Saúde Familiar Prelada, ACES Porto Ocidental

²Associação para a Cooperação e Desenvolvimento Garcia de Orta (AGO)

³Instituto de Higiene e Medicina Tropical – Universidade Nova de Lisboa

⁴Direcção-Geral da Saúde

⁵Unidade de Saúde Familiar Marginal, ACES Cascais

Background and aim

Portuguese primary health care commissioning (PHCC) aims at improving performance results through targets for selected indicators and an incentive scheme. Transparent negotiation and evidence-based selection of indicators are critical.

Despite annual reviews, there is room for improvement concerning the definition and validation of performance indicators and targets.

This work aims at introducing a rationale for selecting relevant and adequate performance indicators in PHCC, in response to current challenges and shortcomings undermining practices' performance assessment.

Method

An international literature review was conducted on criteria and methods for indicator selection and validation. All commissioning indicators for Portuguese PHC practices were analysed and trends were observed for 2009-2015.

A workshop with political, clinical and academic stakeholders was held on challenges, solutions and technical evidence on current indicators. Conclusions were analysed and drafted as policy recommendations for 2015 PHCC.

Results

Some issues pervaded Portuguese PHCC performance indicators: lack of scientific evidence-base and specification detailing (in order to avoid inaccurate records). The whole process is still poorly linked to practices' context and to national, regional and local health priorities.

Performance has been predominantly measured by process indicators and some of the priority health conditions (e.g. heart failure) and patient-reported outcome indicators have been neglected. Nevertheless, there is an increasing focus on results, on indicators' scientific validity and at improving the negotiation process.

Conclusions

Although performance indicators are selected for three years in Portugal, it is important to reconcile stability and flexibility goals in performance assessment. Annual commissioning reviews should encompass improvement to the indicators themselves, whenever relevant.

A multi-step performance indicator appraisal and validation process is recommended. Indicators should link to existing health priorities, be widely discussed among stakeholders and arise from consensus on the indicators' value: clinical relevance; scientific validity; link to the care process; potential for improvement; simple appraisal.

Keywords: indicator, performance measurement, primary health care, evidence, validation

1 - Commissioning

e-mail: antoniopereira@gmail.com

Commissioning

Process of evaluation of a population's health needs, and planning, implementation and monitoring of services in order to meet those needs, according to availability of resources.

Commissioning

3 - Limitations – some national findings

Limitations – some national findings

Shortcomings of current indicator-setting processes:

- Lack of scientific evidence to support some performance indicators
- Insufficient detail in indicator specifications for measurement
- Indicator development & implementation still poorly linked to:
 - National health priorities
 - Practices' context characteristics
- Impact on practice and performance measurement:
- Inaccuracies & errors in clinical records
- Lower reliability of indicators' final results
- Consistently higher performance targets regardless of context specificities

4 - Improvement proposed approaches

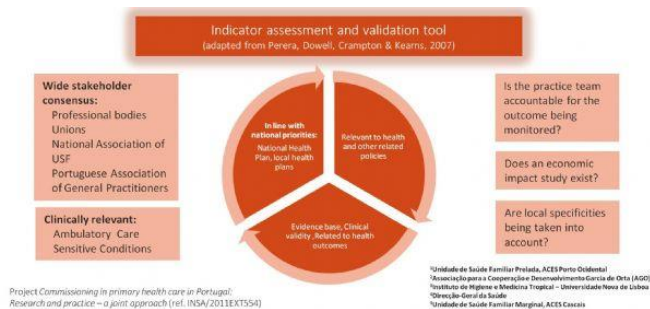

Improvement proposed approaches

Widen the scope of national-priority health conditions' indicators (respiratory and mental health areas)

Better overall indicator validation process:

- Identification of performance outcomes according to national, regional and local health priorities
- Definition of multi-disciplinary commission for ensuring indicator utility and usability
- Use of indicator validation tool for testing indicator usefulness

CONCLUSIONS

CONCLUSIONS

Project Commissioning in primary health care in Portugal:
Research and practice – a joint approach (ref. INSA/2011EXT554)

2 - Key principles

Key principles

- Evaluation of practices against performance targets
- Technical and scientific rationale for selecting indicators
- Performance targets negotiated with practices for a set of outcomes/indicators
- Financial incentives linked to achievement of performance goals

Want to change your doctor.....but why?

Adela Ioana Uta¹, Claudia Elena Uta¹, Carlos Isanta Pomar¹, Lia Anguelova Valentinova²

¹Department of Primary Care, Health, Zaragoza, Spain

²Department of Endocrinology, Valencia Agency of Health, Castellon de la Plana, Spain

OBJECTIVES:

The relationship between a doctor and a patient is a very important concept in health care, as it is associated with a greater adherence to the treatment, more satisfaction of the patient and a better prognosis.

The satisfaction as well as the quality of assistance received is the determining factor in the voluntarily change of doctors by the patients.

Determining the most common reasons for the voluntarily change of doctors is one of the objectives of our study.

METHODS-MATERIALS:

It's an exploratory study carried out between 15 of May and 16 of July 2014 in a Healthcare Centre in Zaragoza, Spain with a total of 15 doctors and 15.185 patients.

For the study we created a questionnaire with a closed question system about the motives of their wish for change and only one open question where there could detail their reason, collecting the data from the patients anonymously. We also included demographic data of age and sex.

RESULTS:

The total number of patients that changed their doctor in the two month study was 35 with a mean of 1.5 patients per doctor per month.

Regarding the reasons 16 patients listed as a motive inconvenient working hours, 17 patients listed a bad relation and 2 patients wished to change their doctor because they were consulted every time they needed attention by a different doctor in the last year.

CONCLUSIONS:

The main reason for wanting to change their personal doctor is the dissatisfaction of the patient with his doctor. The rate of patients changing doctors in the Healthcare Centre is elevated, but similar to another study carried out in another Healthcare Centre in the same city.

We conclude that there are 2 categories of doctors: ones that receive patients and others that tend lose them.

Keywords: family physician, patients care, effects of physician communication, practice management

Frailty in older people; a common European challenge that deserves a joint response from national health and care systems

Ines Garcia Sanchez, Ana Carta, Jorge Pinto Antunez
 DG SANTE European Commission. Health and Innovation Unit

BACKGROUND-AIM:

Europeans are living longer, but often with one or more long-term medical condition. Moreover, for r many citizens aging brings disability, frailty and/or chronic diseases. Although commonly used interchangeably to identify vulnerable older adults, those are distinct clinical entities causally related, often associated although not exchangeable. Their correct use will improve our understanding of the problems affecting older patients and lead to improved strategies and actions, affecting both the clinical setting and the management of care and social areas.

The European Innovation Partnership on Active and Healthy Ageing is a European Commission's answer to the demographic challenge Europe is facing. Aiming to improve the quality of life of older people and enable them to stay active and healthy for longer. During its implementation plan it has taken forward frailty prevention through different channels such as an Action Group, Frailty Annual Conferences (2012, 2013) and funding instruments supporting related projects.

METHOD:

A 2 years Joint Action on frailty prevention, funded under the EU Health Programme 2015, supporting cooperation between Member States to establish frailty prevention as a priority of European health and care systems and unveil suitable solutions.

RESULT:

This Joint Action will improve our understanding of long-term care medical conditions affecting older patients and develop improved strategies for screening, assessment and intervening against frailty, disability and multi-morbidity. It will contribute to a more effective response to the needs of older people and reduce inefficiency in

care delivery through innovative organisational approaches and better combinations of professional and informal care.

CONCLUSION:

Frailty prevention is a global common challenge. Addressing it collectively will help progressing at national and European level. Active involvement in this Joint Action gives Member States the possibility to find solutions to unsolved problems and develop common frameworks and guidelines to tackle frailty through integrated care strategies.

Keywords: Frailty, ageing, EU policy, prevention

Co-management Shared Care Unit between Family Medicine and Internal Medicine

Jaime Barrio¹, Kristina García¹, Jaime Rodríguez¹, Pablo Gómez¹, Miriam Uzuriaga¹, Arancha Barranco¹, Miguel Martínez¹, Mar Contreras¹, María Teresa Beca², Carmen Suárez¹

¹Hospital Universitario de La Princesa. Madrid. España

²Hospital General Universitario Gregorio Marañón. Madrid. España

o Background & AIM:

The Co-management Shared Care Unit between Family Medicine (FM) and Internal Medicine (IM) from Hospital La Princesa was created in 2011 to deliver more efficient care to complex patients through an IM doctor who coordinates the healthcare. This shared healthcare is done in person or through phone/email. The groups of patients referred to the unit by the FM doctor include:

- A. Multiple Chronic Conditions Patients (MCCP) who are followed by FM.
- B. MCCP who visit their FM doctor after discharge from IM hospitalization.
- C. Priority care patients for malignancy suspicion.
- D. Patients who need immediate follow-up.
- E. Patients with common diseases who require consultant expertise.
- F. Patients with abnormal labs/diagnosis/treatment doubts who require consultant expertise.
- G. Patients with complicated social conditions.

o METHOD:

A descriptive retrospective study from January 2013-April 2014 was done. We collected socio-demographic, clinical, functional, and utilization data of 302 patients belonging to the 4 health centers which participate within the unit.

o RESULTS:

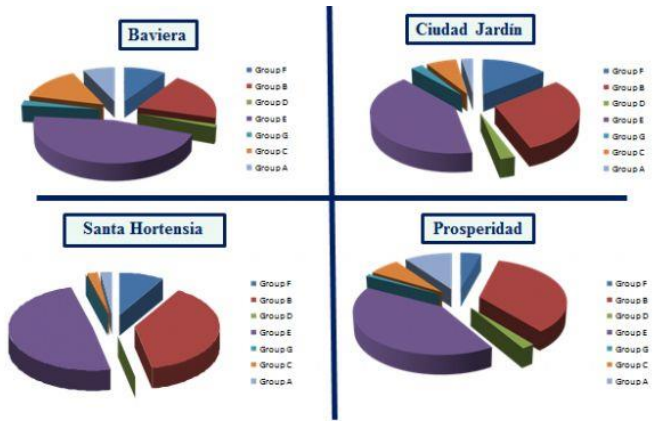

The average age was 70.9 and 59% were women. The patient breakdown was 44% group_E, 29.8% group_B, 8.9% group_F, 8.2% group_C, 5.9% group_A, 1.6% group_D and 1.6% group_G. 753 visits, 89 telephone consults, 146 ER visits, 90 hospitalizations and 96 daycare visits were performed. 52% of patients were discharged, 39% remained in the unit and 4.6% were deceased. Within the MCCP group, the average age was 80.5, average number of drugs used per day was 8.7, average ER visits was 0.7, average number of hospitalizations was 0.5 and the average Barthel Index was 75.1.

o CONCLUSIONS:

Patients in the MCCP group were older, used more drugs and resources and had more severe functional impairment. There was no difference in reason for referral between the health centers. Telephone was an important way to communicate with the patients.

Praksis Plus: Three Years of a National Support Network for Establishing GPs (2012-2014) - the Danish Case

Ulrik Bak Kirk, Eva Schandorf, Jonas Hessler, Jon Zwisler, Dorte Navntoft, Rikke Pilegaard
Danish College of General Practitioners (DSAM), Copenhagen, Denmark

Background

In 2012, the Danish College of General Practitioners (DSAM) – the Scientific National Representative Body for all GPs in Denmark – recognized and articulated the need for a Support Network for Establishing GPs. GP trainees, Establishing GPs and the College (DSAM) identified more specific needs: More targeted support was demanded and requested. From this Praksis Plus was developed.

Methods

The concept Praksis Plus combines an interactive PDF with workshops for Establishing GPs in order to maintain and update the electronic handbook. Notifications about updates were made by using the Praksis Plus website together with social media.

In 2013, the full Praksis Plus Support Package was launched at DSAM's Annual Meeting. Furthermore, a National Executive Board was established, which comprised of 5 Newly Established GPs and 3 GP trainees. The Praksis Plus Executive Board functions as the Praksis Plus steering committee.

In 2014, DSAM allocated further funding for the national Praksis Plus Support Package, while the development of the regional Praksis Plus Zealand concept took place. Praksis Plus Zealand will introduce a welcome package containing a meeting for Established GPs, a regionally specific interactive PDF together with an e-learning module.

Results

Within its first three years (2012-2014), the Praksis Plus Support Package has achieved a great deal:

- The Praksis Plus interactive PDF and dedicated webpage.
- Representation at Annual DSAM Meetings.
- Workshops at Lægedage (biggest CPD conference, +2.500 GPs).
- 100 % free courses and conferences.
- Semi-structured national Praksis Plus Executive Board.
- Praksis Plus Zealand concept package for newly established GPs regionally.

Conclusions

Much has already been accomplished, but it is the intention to:

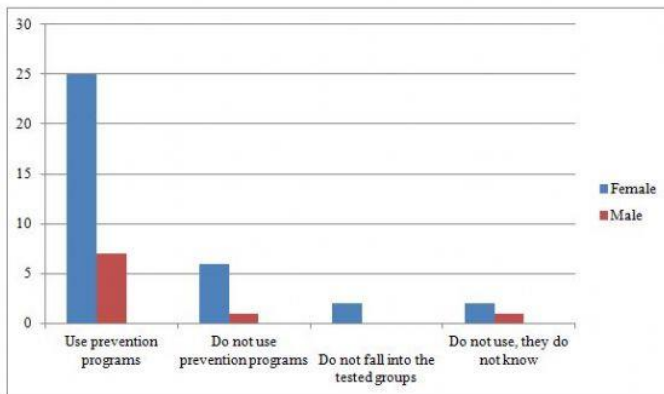

- Extend the Praksis Plus organizational framework
- Growing the network of Newly Established GPs and GP trainees
- Getting structured enhanced involvement of Denmark and Praksis Plus in the WONCA networks

The role of non-financial incentives on Family Doctors/General Practitioners

Maria Luisa M Pettigrew¹, Stephanie Kumpunen², Nick Mays¹

¹Department of Health Services Research and Policy, London School of Hygiene and Tropical Medicine, UK

²Nuffield Trust, London, UK

Background & Aim

There is substantial literature examining mechanisms which motivate and modify the behaviour of healthcare providers, in particular, systematic reviews on the impacts of financial incentives on family doctors' behaviours. However the literature exploring the role of non-financial incentives on family doctors is more disparate and has not been systematically conceptualised or appraised. This poster aims to present a conceptual framework regarding the role of non-financial incentives on family doctors' behaviours.

Method & Results

The development of this framework will be informed by a scoping review of the literature on motivation and behaviour change in healthcare providers. The framework will be used to guide a systematic review and realist review on the evidence of the role of non-financial incentives on the behaviour of family doctors as the next stage of the project.

A systematic review aims to identify, evaluate and summarise the findings of relevant studies in order to make the available evidence more accessible to decision makers. However in cases when the evidence-base is heterogeneous and the 'intervention' (in this case a non-financial incentive) may be complex and subject to multiple contextual variables a realist review aims to explore in more depth what may work where, when and how by developing 'programme theory' of why it may work.

Conclusion

A conceptual framework will help understand what non-financial incentives can potentially be utilised in primary care and how they aim to lever the intrinsic to extrinsic spectrum of motivation. The framework will later be refined based on their findings of the systematic and realist reviews.

Study on effectiveness of care provided by the Mobile Emergency Care Service - SAMU / DF during 2013

Ubirajara José Picanço De De Miranda Junior¹, Vinicius Neves Bezerra¹, Leonardo Dos Santos Ferreira¹, Olga Messias Alves De Oliveira², Rafael Olinto²

¹Escola Superior de Ciências da Saúde - ESCS - Federal District - Brazil

²Mobile Emergency Care Service - SAMU

Background and AIM: Emergency Ambulance Service of the Federal District (SAMU / DF) performs urgent care / emergency and through phone calls prioritizes use the type of care, with or without medical staff (basic or advanced), in each case evaluated. This study described the effectiveness of the services performed by the SAMU / DF in 2013. METHOD: An exploratory study, cross over the telephone solicitations made to the Regulation Center of SAMU / DF in 2013, describing: total and type of connections made; first and second decision; increased demand for places; the estimated response time; sent resources; canceled missions; and use of advanced ambulance. RESULTS: In 2013 854.160 calls were recorded, and only 28.3% were covered by doctors. The links interrupted, hoaxes and mistakes, amounted to 67.7%. In the first medical decision, only 34.8% of regulations were defined as "necessary and possible intervention." In the second decision, 65.2% were classified as "necessary and possible removal." The regions with higher demand for care were the most densely populated and social vulnerability. Of the total resources used, 88.7% were basic ambulances and 11.3% unit advanced support. The average total time of SAMU response was 17.3 minutes, displaying inconsistency, 13.0 minutes in the first half and 21.6 minutes in the second half. 12303 were canceled missions, 15.1% of the total sent resources. The

main cancellation reasons were: removal by another institution, the central regulation cancellations, occurring already answered, patient refuses care, patient is not in place and death (6.02%). CONCLUSION: The SAMU / DF cannot fully do its job because the medical regulation is covered with little more than a quarter of the total demand demanded the Central regulation. Further research, especially tracking, supporting an improvement in the management of pre-hospital care in the capital of Brazil.

Women's Health Monitoring in suburban area of the Capital of Brazil

Fernando Ferreira Nata

Escola Superior de Ciências da Saúde - ESCS - Federal District - Brazil

Background and AIM: The region studied is a suburban neighborhood inhabited by popular urban working classes of central Brazil called Ceilândia, characterized by areas with regular urban infrastructure combined with large pockets of poverty and precarious socioeconomic status. To survey health monitoring indicators related to women issues linked to prenatal, postpartum and reproductive planning in 11 basic health units located in Ceilândia. METHODS: Cross-sectional study in 2013 in a population of 147.405 women of childbearing age in a total of 414.531 inhabitants in a suburb of the Brazilian Federal Capital. The data collection was executed during the assistance provided by the health workers in the local community. RESULTS: At first, the indicators assessed the extent to which services provided to the community in 2013 reached the results recommended by regulators of primary health care in Brazil. In its second stage, the study proposed the analysis of the indicators done by Ceilândia health workers themselves, so that from these data, there could be proposals to solve the identified problems. CONCLUSIONS: The result is a series of regulations adopted since 2014 by health facilities in order to enhance the work related to the primary health care of women. Among them, there is the need to conduct training and in-service training for professionals to better meet the prenatal component; as well as the necessity to perform networking activities between Ceilândia Regional Hospital and basic health units to ensure appointments in early postpartum period by the 10th day after birth; hold meetings to better guide the planning within the reproductive health unit, but also in schools to reach the teen audience.

P-0838**Health expenditure of chronic widespread pain in primary care**

Enma Marianela Morales Espinoza¹, Belchim Adriyanov Kostov¹, Daniel Cararach Salami¹, Pilar Brito Zerón², Manuel Ramos Casals², Antoni Sisó Almirall¹

¹Consorci d'Atenció Primària de Salut Eixample (CAPSE). Transversal Group for Research in Primary Care. Institut d'Investigacions Biomèdiques August Pi i Sunyer, (IDIBAPS). University of Barcelona. Spain

²Clinic Institute of Internal Medicine and Dermatology (ICMiD). Departament of Autoimmune Diseases. Hospital Clinic of Barcelona. Spain

OBJECTIVE: Impact on health expenditure in patients with Chronic Widespread Pain (CWP) in Primary Health Care.

METHOD: Multicenter case-control study (age-gender matched) was carried out. A representative sample of 3048 patients was recruited during 2011-2012. American College of Rheumatology classification criteria was considered for CWP diagnosis. Health care resource utilisation were evaluated. Direct costs (primary healthcare visits, laboratory and diagnostic tests, prescription medications, emergency room visits, hospital admissions and major/minor surgery) and indirect costs (lost productivity) were measured.

RESULTS: 168 patients met criteria for CWP (prevalence 5.5%; 95%CI:[4.75%–6.38%]). One hundred and thirty consented to participate, 120 (92.3%) were women; mean age 61.7±11.7. Related painful syndromes: fibromyalgia in 65(50%), osteoarthritis in 53(40.8%) and autoimmune or rheumatic diseases in 11(8.4%); Subjects with CWP were reported to visit more time to Primary health care physicians (11.8 vs 8.4; p>0.001), hospital specialist physicians (3.9 vs 2.4, p=0.002) and more laboratory test (1.8 vs 1.3; p<0.001). CWP cases received more prescription than control group (818€ vs 311€; p<0.001): drug expenditure represents 41.31% of direct health expenditure. Mean total direct costs in CWP-patients were 1980 ± 1811€ while in control group were 1003 ± 826€ (p<0.001). Mean indirect costs in CWP-patients were 1474 ± 5361€, while in control group were 328 ± 2255€ (p=0.013). Global costs in CWP-patients were 3454 ± 5604€, and 1331 ± 2416€ in control group (p<0.001).

CONCLUSION: Patients with CWP have a very high health care costs, both direct medical costs (specially drug expenditure) and indirect costs (lost productivity due to sick leave).

P-0839**First aid notions for public and private school communities of Federal District, Brazil**

Mônica Beatriz Ortolan Libardi¹, Júlia Maria De Oliveira Duarte¹, Olga Messias Alves De Oliveira¹, Ubirajara José Picanço De Miranda Junior²

¹Mobile Emergency Care Service - SAMU 192 - Federal District - Brazil

²Superior School of Health Sciences - ESCS - Federal District - Brazil

Background and AIM: The Public Education Network of the Federal District has 664 public schools and 432 private schools registered in the Secretary of Education and distributed in the 31 administrative regions, which are attended by more than 400 thousand students. With the implementation of the Emergency Ambulance Service (SAMU 192/DF), which provides health care to the population, and is operated by the Regulation Center, there was the need to instruct schoolchildren on how to properly use the pre-hospital treatment and how to start first aid care until the health workers arrive on the scene. In 2007, was launched the Samuzinho® Project in order to bring to the community knowledge the SAMU 192-DF service and the "Samu in Schools" program was created, in order to clarify when and how to call the pre-hospital treatment (APH) and to teach notions of first aid care to the school community. **METHOD:** The project has been running for 8 years, involving teachers, monitors, directors, janitors, secretaries, engineers, educators, and using the active construction methodology of basic life support for lay people, that is, those who are not health professionals, until the arrivals of the SAMU/DF team. **RESULTS:** The implementation of the Project provided a change of behavior in the school community, comprising the

acceptance, commitment and assimilation of the importance of the use of the Service, as well as starting the basic care needed to attempt the citizen survival. By March 2015, over 13,000 people were involved in this construction of knowledge. CONCLUSIONS: The continuing educational process has facilitated awareness of first aid notions among teachers and students of public and private network of the Federal District.

Reduction in prank calls to prehospital emergency care services -“Samuzinho Project”®

Mônica Beatriz Ortolan Libardi¹, Júlia Maria De Oliveira Duarte¹, Rodrigo Belém Caselli¹, Ubirajara José Picanço De Miranda Junior²

¹Mobile Emergency Care Service - SAMU 192 - Federal District - Brazil

²Superior School of Health Sciences - ESCS - Federal District - Brazil

BACKGROUND AND AIM: The Ambulance Service of the Federal District of Brazil - SAMU 192-DF, under the Ministry of Health, is a prehospital care service accessed through telephone call to a Central Medical Regulation. The high prevalence of undue calls is a problem that occurs in this service. This problem is responsible for the overload on the system, professional burnout and even dislocation of ambulances to unnecessary places, leaving unattended victims who really need help. The majority of these calls were prank calls, made by schoolchildren and also by adults, representing about 60% of the undue calls. In 2007, the Samuzinho® Project was launched in order to bring to the community knowledge the SAMU 192-DF service, developing their spirit of solidarity, citizenship and service to others. Thus, this project aims to highlight the importance about the correct use of telephone to call for a prehospital care service.**METHODOLOGY:** Realization of first aid notions training course for schoolchildren and adults. It were used story creation ludic methods, scrapbook and collage, clay handling, and the real presentation of ambulances and teams, moto-ambulance and even helicopter. It was given a certification of completion for the participants.**RESULTS:** By March 2015, a total of 13,055 people were trained. Among them there were children, teenagers, primary school, high school and college's professionals, charity companies and institutions, kindergartens and the community in general, elderlies and prison system's employees. As a result, there were a reduction of 51% on undue calls, remaining a rate of 9% of misuse of telephone to call the service.**CONCLUSIONS:** This training programme has demonstrated the importance of community awareness about the correct use of a help communication tool and, as a result, the improvement on the prehospital emergency care service.**KEY-WORDS:** Prehospital; ambulance service; SAMU 192-DF.

Quality of life in Mobile Emergency Care Service of the Federal District - SAMU 192/DF-Brazil

João Ricardo Simczak Prates¹, Rodrigo Belem Caselli¹, Olga Messias Alves De Oliveira¹, Ubirajara José Picanço De Miranda Junior², Luciana Stoimenoff Brito³

¹Mobile Emergency Care Service - SAMU 192 - Federal District - Brazil

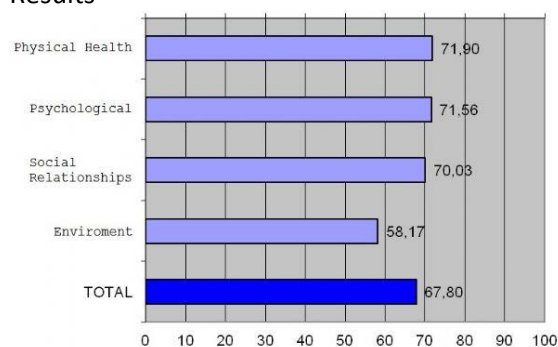

²Superior School of Health Sciences - ESCS - Federal District - Brazil

³University of Brasilia - Brasil

Background and AIM: When performing a job, the individual inserted in a context and the social representation of this activity impacts both in their life and in their welfare, requiring attention to their quality of life. This project took into consideration the stressful nature of working in emergencies and other peculiarities of this service and the objective was to analyze quality of life of workers of the Emergency Service of the Federal District - SAMU/DF. METHOD: Application of the test WHOQOL-BREF in 425 workers of various professional categories, representing between 40% and 45% of the total workforce. RESULTS: We found similar results between the different groups of work, with some differences among those who work directly in the field service and the others, showing good scores. The physical domain had good scores (71.9%), but the facet "sleep and rest" (58.93%) appeared quite below average. The psychological domain also presented a good score (71.56), with the "self-esteem" facet (84.8), representing the highest rate in the test, although, "positive feelings" (61.25), appearing in the same domain, presented lower score. Environment was the domain (56.77) that presented lower scores in general, and health and social care: availability and quality (45.76), participation in opportunities for recreation / leisure (45.81) and physical environment (pollution / noise / traffic / climate) the lowest and unique indexes to presented scores below 50. The Social Relations domain presented averaging high scores, with the facet "social support" (66.29) the negative highlight, although has reasonable score. CONCLUSIONS: The application of the WHOQOL-Bref in SAMU/DF presented that there is, overall, a uniform assessment by the workers, whose groups have very similar self-assessments. Further studies are needed to evaluate the possible correlation of these factors with low levels of quality of sleep and rest as well as leisure activities.

Latest communication interactions with patients outside the Primary Health Care Centre

Anna Forcada Arcarons, Engracia Costa Atienza, Silvia Altimiras Rovira, Laura Almendros Plana, [Alícia Díaz Pilco](#)
institut català de la salut

BACKGROUND & AIM

Overload in Primary Health Care has triggered the creation of new forms of communication with users.

In order to relieve the visits in the centre, we have developed new forms of communication with patients.

These are telephone visits (TV), home visits (HV) and virtual visit (VV).

Thereby, we attempt to improve the utilization of healthcare resources efficiently, increase patient access to the best possible resources and promote self-care and prevention of patient.

METHODOLGY

TV, HV and VV (2013) have been evaluated by our computer system (ECAP) and they have been compared with the center visits (CV) of the professionals who work in the center (Doctors, Nurses, Pediatrics).

Then we have compared data on VV 2012 and 2013 as it has been the last type of visit established in the center.

Data are included by doctors, paediatricians and nurses (adults and paediatrics):

- CV 2013: 48199 Doctors (82.1%) visits; Paediatricians 11291 (90.6%) visits; 26347 nurses (78%) visits.

- TV 2013: 4319 Doctors (7.3%) visits; Paediatricians 710 (5.7%) visits; nurses in 2130 (6.3%) visits.

- HV 2013: 1408 Doctors (2.4%) visits; Paediatricians 1 (0.00008%) visit; Nurses in 2819 (8.3%) visits.

- VV 2013: 4817 Doctors (8.2%) visits; Paediatricians 465 (3.7%) visits; Nurses in 2502 (7.4%) visits.

Progression of virtual visits since its establishment in the centre:

- VV 2012 3530 visits (57% Doctors, Nurses 40.1%, 2.9% Paediatricians).

- VV 2013 7791 visits (62% Doctors, Nurses 32.1%, 5.9% Paediatricians).

CONCLUSIONS

Trend persists in the visits in the centre, while gradually increasing the TV and VV in the years studied. The extension of contact channels patient - healthcare professional is an opportunity to increase the quality of services provided and relieve healthcare centres.

Keywords: KEYWORDS Patient communication; health outside professional relationship; new ways.

P-0843

Evolution of the non-contact visits in our Primary Health Care Centre since its introduction

Anna Forcada Arcarons, Engracia Costa Atienza, Silvia Altimiras Rovira, Laura Almendros Plana, [Alícia Díaz Pilco](#)
institut català de la salut

BACKGROUND

The overloading in primary healthcare has led the need to find other non-contact ways of communication to relieve the service.

It was established a non-contact visit in the centre (virtual visit-VV).

Its PURPOSE: to serve the needs of patient who not require a visit in the centre.

Define subcategories: healthcare data (INT_ACTIVA), Editorial clinical report (INF_CLINIC), Medical Record Review (REV_HC), Review prescription (REV_PPF), Patient transport (TRANSPORT), Review Temporary disability (REV_IT), Return of laboratory results (RESULT_LAB), Return orders clinics (RESULT_OC), Other (OTHER).

AIM

To improve the utilization of health care resources efficiently and increase patient access to the most appropriate resources.

METHODOLOGY

Evaluation of the VV since its inception in 2012 until 2014 by our computer system (ECAP) of the professionals who work in the centre (doctors, nurses, Paediatricians).

Quantify visits according to subcategories.

RESULTS

There are 11 doctors and 11 nurses for adults and 4 doctors and 4 nurses for paediatric in the centre.

Data are included by doctors, paediatricians and nurses (adults and paediatrics):

- VV 2012: Doctors 2009 (57%); Paediatricians 101 (2.9%); Nurses 1420 (40.1%) visits.
- VV 2013: Doctors 4829 (62%); Paediatricians 465 (5.9%); Nurses 2502 (32.1%) visits.
- VV 2014: Doctors 6391 (68.6%); Paediatricians 532 (5.7%); Nurses 2396 (25.7%) visits.

Evolution of the VV in this period:

- VV 2012: 3530 visits (34% REV_HC, REV_IT 31%, OTHER 26.7%).
- VV 2013: 7791 visits (30% REV_HC, 26.5% INT_ACTIVIA, OTHER 20.1%, REV_IT 18%).
- VV 2014: 9319 visits (37.8% INT_ACTIVIA, 32% REV_HC, 12.8% REV_IT, OTHER 10.7%).

CONCLUSIONS

It's doubled the use of this type of visit established in the centre.

It's included a variety of items that help to detail the type of work that healthcare professionals perform.

It's an opportunity to increase the quality of services provided and relieve in health care centres.

P-0844

The role of family doctor in anxiety problems among students due to tsunami risk in Padang City West Sumatra

Rima Semiarty Kamardi¹, Hardisman Dasman²

¹Departement of Public Health, Faculty of Medicine Andalas University, Indonesia

²International Public Health Studies Faculty of Medicine and Health Sciences Flinders University Bedford Park, Adelaide Australia

Padang is one of the city in Indonesia that have a high risk to earthquakes and tsunami disaster. After Aceh Tsunami in 2006 and big earthquake in 2009 in Padang, there were area that consider red zone which are closed to danger area (near the beach) and green zone that relatively far from danger area.

For those who survived from tsunami attack, will face mental trauma that still remain such as anxiety.

.This study examined the correlation of the tsunami risk to the anxiety level on children in the red and green zone of Padang after conducted simulated on earth quake and tsunami for elementary school.

This research is an observational analytic study using cross sectional design with total sample of 117 responden were selected by stratified random sampling. from elementary school located in red and green zone.

The data were collected by using a HRS -A questionnaire analyzed by chisquare test.

The results of this study indicate the level of anxiety in children in red zone higher then in green zone..

After intervention from group of family doctor, colaborated with medical students in public health clerkship, the level of anxiety decrease significantly.

⁴Associação para a Cooperação e Desenvolvimento Garcia de Orta (AGO), Lisboa, Portugal

⁵Associação para a Cooperação e Desenvolvimento Garcia de Orta (AGO); Instituto de Higiene e Medicina Tropical – Universidade Nova de Lisboa, Lisboa, Portugal

In the UK, the 75th percentile of the results achieved in the last two years for each indicator is considered the reference value for setting targets for primary health care (PHC) commissioning for the following year (Brilleman et al., 2013).

This methodology was proposed by the authors of this study and it was welcomed by the Portuguese responsible entities that defined the 80th percentile instead as a reference and upper threshold for setting targets for the Portuguese PHC commissioning in 2015.

This research focus on the targets of the PHC units' indicators and the importance of considering the units' socio-demographic context.

Eleven national indicators related to healthcare access, performance, satisfaction and efficiency were analysed for 2013 and 2014 and all PHC units of Portugal were assessed.

Firstly, the 75th percentiles of the indicators' results from 2013 were calculated for 1) total of units, per organisational model; 2) units clustered by its organizational model, age (years since starting) and size. Then, indicators' results from 2014 were analysed, in accordance with how many of them were upper than the percentiles calculated for the indicators' results of 2013 in the two situations and the difference was tested using t-test.

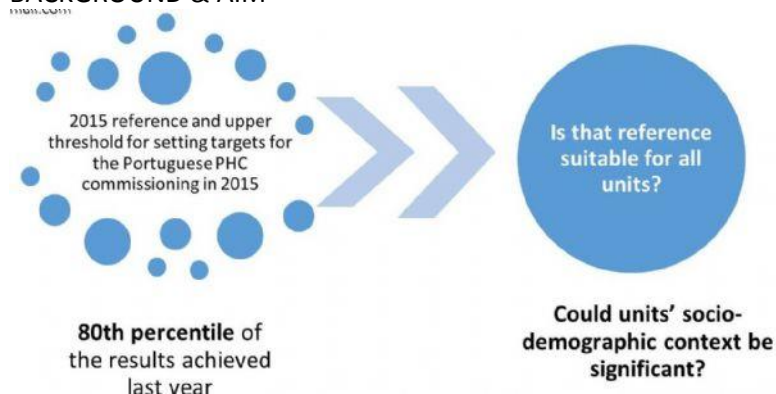

For 2014, there were more units overcoming the 75th percentile when the percentile was calculated for units clustered by organizational model, age and size (2019 units) than when the percentile was calculated for the total of units per organisational model (1840 units) ($p < 0,001$).

It was shown that the evaluation of the units when the target setting consider PHC unit's organizational model, age and the size was more appropriate than the one taking into account only the organizational model, which reinforce the importance of introducing the context when defining targets.

Further studies should consider more context variables.

Context

In the UK, the 75th percentile of the results achieved in the last two years for each indicator is considered the reference value for setting targets for primary health care commissioning for the following year.
This methodology was proposed by the authors of this study and it was welcomed by the Portuguese responsible entities that defined the 80th percentile instead as a reference and upper threshold for setting targets for the Portuguese PHC commissioning in 2015.

Method

Eleven national indicators related to healthcare access, performance, satisfaction and efficiency were analysed for 2013 and 2014 and all PHC units of Portugal were assessed.

75th percentiles of the indicators' results from 2013 were calculated for:
1) total of units, per organisational model
2) units clustered by its organizational model, age (years since starting) and size.

USF (Family Health Units) - PHC Reform 2005

- Voluntary enrolment
- Small, public, multi-professional, stable and self-organised teams
- Organisational, functional and technical autonomy
- Mixed payment system linked to performance

Variables

- Age (years since starting)
- 0-2 Years
 - More than 2 years
- Size (number of family doctors)
- 0-4 family doctors
 - 5-9 family doctors
 - More than 9 family doctors
- Organisational model
- UCSP → traditional model
 - USF-A → Family Health Unit Model A
 - USF-B → Family Health Unit Model B

Results

There were more units overcoming the 75th percentile when the percentile was calculated for units clustered by organizational model, age and size (2019 units) than when the percentile was calculated for the total of units per organisational model (1840 units) ($p < 0,001$).

	UCSP-M	USF-A	USF-B
Organisational Model	$p < 0,001$	$p < 0,001$	$p < 0,001$
Age	Not significant	$p < 0,001$	Not significant
Size	$p < 0,001$	Not significant	Not significant

Conclusions

It was shown that the evaluation of the units when the target setting consider PHC unit's organizational model, age and the size was more appropriate than the one taking into account only the organizational model, which reinforce the importance of introducing the context when defining targets.

Role of Public Health Promotion in prevention of Road Traffic Accident

Menkher Manjas¹, Abdiana Ana², Rima Semiarty Kamardi³

¹Departement Of Surgery, M Jamil Hospital, Medical Faculty, Andalas University, Indonesia

²Department of Public Health, Medical faculty Andalas University Indonesia

³Department of Public Health, Medical faculty Andalas University, Indonesia

Estimated that 1.2 million are killed a year among 50 million injured people in Road Traffic Injuries (RTIs). RTIs are a huge major endemic public health problem, which annually increasing globally

The most cause increased of traffic accident are driver, passenger, Lack of transportation facility,

Keywords: Road traffic accident, socialisation

Prof. Menkher Manjas, Sp.B, Sp.OT, FICS

Background:

- Road Traffic Injuries (RTIs) are a huge major public health problem which annually increasing globally. Estimated that 1.2 million people were killed a year by RTIs among 50 million injured people. Its become the 3rd cause death around 10-40 year old. In the world, at least one case died every 26.3 seconds. In Indonesia the incidence more high where one people died every 17 minutes. During year 2014 at Padang West Sumatera, 64% of all deaths caused by RTIs. The Global cost of management increase year by year and in total minimally 2% of GDP.

Method:

The study was conducted by gathering 120 students from 3 different schools in Padang from January to March 2015. All of the students were given written test before, which consist of questions about traffic rules, regulations and casualties caused by traffic accidents. After the first test, they were given a counseling session for 2 hours each day in 7 days by the public health lecturers and the police officers. After that, the second test were hold 3 months later to see the impact of the counseling.

Result:

Figure 1: Before the counseling

Category	Correct	Wrong
High School	~15	~25
High School	~10	~20
High School	~12	~22

Figure 2: After the counseling

Category	Correct	Wrong
High School	~35	~10
High School	~30	~15
High School	~32	~12

Discussion:

Through counseling, the Public Health department and the Police Department could increase the knowledge, attitude and skills of the students in traffic regulations and casualties. We hope that the knowledge could be spread to others and traffic accidents in the future could be decreased.

Conclusion:

- RTI are a huge national problem
- Road traffic crashes are predictable and can be preventable.
- Public Health participate mainly in Health Education in traffic way
- Road safety is a shared responsibility
- The adoption of "system approach" in road safety hope an sharp reduction in crashes and casualty

Demand and use of health care services - exploring the level of health in a rural area of Crete

Theodoros Vasilopoulos¹, Georgia Arseni², Nikolaos Kontarakis¹, Crysanthi Tatsi¹

¹Health center of Ag.Barbara, Herakleio,Crete, Greece

²Venizeleio Gen. Hospital, Herakleio,Crete,Greece

INTRODUCTION: The demand for health care services, expresses the desire to consume health care services, which turns into active search for such care and is defined by objectively assessed needs, but depends on many factors such as demographic, social and economic characteristics of individuals, the health care system, the price of health services, the level of health etc. For primary care, the use of health services is expressed through indicators of the visits to GPs and other primary care organizations and through the frequency of prescription, and depend largely on the age and gender.

The purpose of this study is to investigate the characteristics of the users of health services in a General Medicine clinic of a rural area of Crete.

METHODS: 638 respondents consisted the study population, and refers to all users of health services who came to a specific general medical clinic at the health center of Santa Barbara Heraklion, with any justification for use of health services on a regular daily basis. Our study was conducted based on a structured questionnaire consisting of qualitative and quantitative questions.

RESULTS: The importance not only of age, gender, educational level and occupational employment and income but also that of the self-reported physical and mental health as perceived by users, is emerging, referring on the demand and use of health care services.

CONCLUSIONS: A new operating model for Primary Health Care is needed to improve the health status of the population, through the prevention of causes of morbidity and mortality, the health promotion and the awareness of users of health services. Basic premise is the education and training of primary health care practitioners to ensure better and more efficient provision of comprehensive health care, including the development and implementation of guidelines, and the application of diagnostic and therapeutic protocols, and clinical audit processes.

Keywords: demand for health services, use of health services, self-reported health, primary health care.

P-0848

Centers of Coexistence and Culture: a new perspective on mental health

Lara Louise Guimaraes Silveira, Rickella Aparecida Alves Moreira

Univerdidade Federal de Goiás, Goiânia, Brasil

Background & Aim

The Centers of Coexistence and Culture are part of the mental health network that arose after the Brazilian Psychiatric Reform, which aims to deinstitutionalization of mental health patients. All this reform seeks to withdraw the patient of mental hospitals and reinsert them in society. These centers carry with it various cultural and socialization activities, empowering them to regain a place in society.

This model has been consolidated as an innovative device playing a significant role in social inclusion of people with mental disorders. Due to its characteristics they are usually implemented in municipalities that have been able to build an effective network of care and assistance to severe and persistent mental disorders. And are justified only in those places where the replacement network of mental health has adequate coverage, especially CAPS.

Method

We observed the operation method of Convivencia Center "Cuca Fresca", which is the only Center of Coexistence and Culture in Goiania - GO.

Results

We observed that patients participating in the project uses this service as a place to connect with others in a healthy way, without prejudice and stigma that exists around mental health patient. The most diverse diseases

are seen at this center and they all perform various theater workshops, painting, computer, music - have a battery - etc.

Conclusions

The Centers of Coexistence and Culture are a great rehabilitation tool for mental health patients in society. In it we don't found only health professionals actually are mostly professionals focused in art and culture (are artists, artisans, "workshop instructors", etc.). So it's needed the support of all network of mental health (especially CAPS and its outpatient visits) in maintaining the mental health of patients.

Keywords: Mental health, Brazilian Psychiatric Reform

P-0849

Primary Health Care Unit: family medicine at the hospital, is it possible?

Leonor Roa Santervas, Bjørn Sletvold, Tanja Tomasevic, Baker Shukri, Samuel Mc Manus

Kommunal Akutt Døgnenhet. Oslo Kommune Helseetaten

Background & AIM:

In 2012 norwegian coordination reform legislation obliged the municipalities to provide inpatient health care within January 2016. They should ensure treatment and care for patients who needed acute help with two conditions, all established services should be better or just as well as alternative offered at the hospitals and should contribute to reduce the number of acute admissions in specialist service.

METHOD:

A multiorganizational project group established the principles of the Primary Health Care Unit (PHCU) in advanced to the opening. There were set admission criteria: the diagnosis in itself will not determine whether the patient can be admitted: expertise, staffing level and therapeutic options will decide. Every patient should be discussed with one staff physician before admission. Maximum admission time are three days.

Results

Oslo's PHCU was openend in Aker sykehus, nowadays there are 52 beds in use. Physicians are family medicine specialist or equivalent qualifications. There is access to x-ray, CT and laboratory services. GPs, emergency doctors and outpatient departments in hospitals can include patients after consulting with PHCU responsible physician by phone. PHCU physician is responsible for diagnostic assessment of patients, treatment plan and monitoring, as well as reports.

Conclusions

Oslo's PHCU provides services following the principles of family medicine. Our goal is to achieve first-class primary health service, not a second class hospital in order to facilitate comprehensive assessment, treatment and follow-up and to avoid overdiagnosis and overtreatment. Shared municipal organization facilitates better communication and cooperation with the different health institutions and provides a seamless and smooth transfer between health care levels.

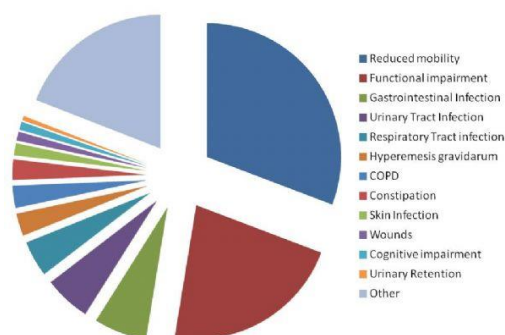

There is a long way to go and many things can be improved, but we strongly believe at this way of treating patients, which mostly are old people, makes them feel better and less sick.

Sleep medicine and referrals savings in Portuguese Primary Health Care

Maria Isabel Climaco, Maria Do Castelo Gouveia

ISCAC, Quinta Agrícola - Bencanta 3040-316 Coimbra, Portugal

Insomnia is one of the most common sleep disturbances in older adults, being even the most prevalent. Up to 40% - 50% of individuals over age 60 report disturbed sleep. The number of elderly that address General Practitioners (GP) in Primary Health Care (PHC) due to sleep problems has been increasing. GP play a key role in the diagnosis of sleep disturbances such as insomnia. As the GP is the first physician to attend patients who have complaints about poor sleep quality, they must be prepared so that a proper diagnosis can be made and treatment of sleep problems can be prescribed adequately. A GP within a health unit is responsible for the clinical decision whether to refer or not a patient to the hospital, for the type of initial referral (e.g. inpatient or outpatient treatment) and for selecting the medical specialty that would be appropriate for the referral. Referral costs depend crucially on these decisions, and costs for sleep medicine are a potential factor influencing savings on referral. For this purpose, a Data Envelopment Analysis model was developed to identify benchmark practices in PHC units, which offer the lowest aggregate referral and sleep medicine costs controlling for the number and age of the patients registered. For the remaining non-benchmark practices, the potential for savings on referral and sleep medicine costs can be obtained by identifying inefficiency sources and gaps relatively to the best practices, thus leading to shaping the changes needed to improve performance.

Keywords: Sleep disturbances, Data Envelopment Analysis, efficiency evaluation

Organization of Family Medicine in Canton Sarajevo, Bosnia and Herzegovina

Fuad Husic¹, Zaim Jatic¹, Dzenana Tanovic¹, Nedžad Mulabegovic²

¹Public Institution Health Centre of Sarajevo Canton

²Faculty of Medicine University of Sarajevo

Backgrounds & Aim

There are two hundred medical doctors working in the family medicine ward in Canton Sarajevo. They are all employees in the Public Institution Health Centre of Sarajevo Canton.

Aim was to find some characteristics of work organization of family physicians.

Methods

Cross-sectional study based on self-administered questionnaire was distributed to physicians (n=60) working in family medicine ward in Canton Sarajevo.

Results

Total n=41 out of the sixty physicians answered questionnaire. Women were n=33 (81%). Average age was 44 years ($\pm 9,95$). Family physicians in Canton Sarajevo have had in the average 49,6 ($\pm 12,02$) patients per day. Of these n=20 patients were unscheduled through an appointment system. Most of the physicians n=24,8 (50%) scheduled patients in ten minutes slots. There were in the average 5 emergency patients daily per family physician. Family physicians n=37 (93%) performed home visits. Fifteen physicians (37%) often were changing the location of their offices.

Conclusion

Family physician are burdened to receive the high number of patients per day. Also, they are faced with a significant daily number of emergency cases. They are often forced to changing workplace. Despite that fact the vast majority of them perform house calls.

P-0852

The readability of currently used consent forms and relationship between legibility with the procedure risk

Andrea Nicolás Carrillo¹, Prof. Aurelio Luna Maldonado²

¹Medicina familiar y comunitaria, Unidad docente Costa de Ponent, Barcelona, Spain

²Department of Forensic medicine, University of Murcia, Spain

In Spanish hospitals it is not normal to write informed consent documents paying attention to legibility. We are using legibility indices in this study in order to analyze the 156 documents we collected from eight different surgical departments. Our aim is to know how well documented and how useful informed consents documents are for surgical patients from Virgen de la Arrixaca Hospital (HUVA). We also studied if there is a relation between the risks of surgical procedures in relation to the legibility of the consent document.

In order to study the surgical risk associated with surgical procedure we created a table to evaluate three surgical risk parameters.

To determine the relation between surgical procedure risk and informed consent legibility we made a bivariate analysis that shows that when risk increases legibility decreases. As we are working with non-parametric data we made use of Kruskal-Wallis test. Results show that there is an inverse relation between surgical procedural risk and informed consent legibility. This inverse relation is higher for departments which involve a greater risk.

Keywords: legibility, readability, informed consent, document, risk,

IFSZ index result

28,2% has a difficult readability for Flesch-Szigriszt Index (IFSZ). 63,5% of all documents belongs to 55-65 border and it is related to a normal readability. 8,3% from those analyzed documents are easily understood; they are related to a score >65 for IFSZ scale.

Bivariate analysis

	IFSZ	Surgical Risk Score	Fernández- Huerta Index
IFSZ	1		
Pearson correlation		-,210**	,719**
Sig. (bilateral)		,009	,000
N	156	156	156
Surgical Risk score		1	
Pearson correlation	-,210**		-,161*
Sig. (bilateral)	,009		,044
N	156	156	156
Fernández-Huerta Index			1
Pearson correlation	,719**	-,161*	
Sig. (bilateral)	,000	,044	
N	156	156	156

To study the relation between risk index and readability we make a bivariate analysis (table 1). This shows statistically significant results for relation between Flesch-Szigriszt Index (Spearman $r=-0,21$; $P< 0,01$), Fernández-Huerta Index and risk index (Spearman $r=-0,161$; $p<0,05$).

Fernandez Huerta Index Result

35,9% are easy to understand. 55% are related to a normal readability by belonging to 60-70 border Fernández-Huerta Index. 9,1% are difficult to understand.

Contrast statistics

	IFSZ	FH Index	Risk index
Chi-squared	93,536	90,833	93,119
Degrees of freedom	7	7	7
Asymptomatic sig	,000	,000	,000

As we are working with non-parametric data we analyze 156 informed consents by using Kruskal-Wallis test. (table 2) We pretend to study if we can establish a relation between the departments from HUVA and the relation to Flesch-Szigriszt index, Fernández-Huerta index and risk index. We found statistic signification for Kruskal Wallis test with degree freedom 7 for 0,0001

Combat Obesity: Affects of Obesity to Fighting Manpower and Military Personnel

Aslan Ozden¹, Unal Demirtas², Yusuf Akyüz³

¹Department of Public Health, Gulhane Military Medical Academy, Ankara TURKEY

²Department of Military Health Services, Gulhane Military Medical Academy, Ankara TURKEY

³Department of Family Medicine, Gulhane Military Medical Academy, Ankara TURKEY

AIM: Worldwide, 2.8 million people die each year as a result of being overweight (including obesity) and an estimated 35.8 million (2.3%) of global disability- adjusted life years (DALYs) are caused by overweight or obesity. Overweight and obesity lead to adverse metabolic effects on blood pressure, cholesterol, triglycerides and insulin resistance. Risks of coronary heart disease, ischemic stroke and type 2 diabetes mellitus increase steadily with increasing body mass index (BMI), a measure of weight relative to height.

METHOD: We made a literature review about "obesity in armed forces."

RESULTS: The rate of BKI>25 in armed forces; Turkey 22%, USA 47%, UK %45, Nigeria %40 and Saudi Arabia 69%. At least nine million 17- to 24-year-olds in the United States are too fat to serve in the military. That is 27 percent of all young adults. Prevalence of overweight and obesity, age 20 and above, male in Turkey is 61% and 24%. This is shown that overweight and obesity is a big problem for armed forces too. Obesity diagnosis of senior officer and sergeant major is more frequency than the young military officer and sergeant. Because of this, senior officer and sergeant major work desk position usually.

CONCLUSIONS: Obesity has negative impact on fighting manpower and manpower planning. Preventive medicine measurements and health promotion must be performed in order to reduce the frequency of obesity and hyperlipidemia which is the main medical disability reason for military personnel.

Keywords: armed forces, obesity, manpower

Performance of Hospital Capacity Usage

Esat Veli Karakoç¹, Erdiñ Ünal², Onur Bayazıt³, Bektaş Murat Yalçın⁴

¹Esat Veli Karakoç: Department of Family Medicine, Izmir University, Izmir, Turkey

²Erdiñ Ünal: Department of Economics and Administrative Sciences, Okan University, Istanbul, Turkey

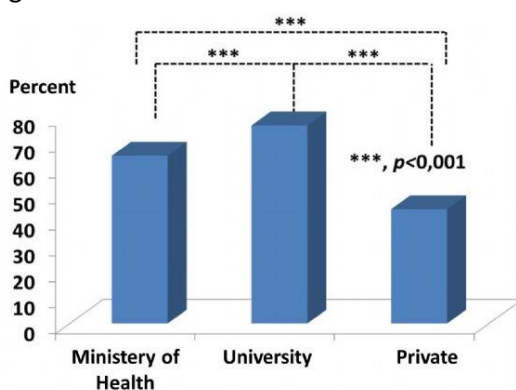

³Onur Bayazıt: Department of Biophysics, Izmir University, Izmir, Turkey

⁴Bektaş Murat Yalçın: Department of Family Medicine, Ondokuzmayıs University, Samsun, Turkey

BACKGROUND and AIM: It is aimed to compare the hospitals which are differentiated according to their ownerships (Ministry of Health, University and Private hospitals) in terms of bed occupancy rate, bed turnover interval, approximate length of stay of in-patients and bed turnover rate, which are indicators of facility usage. **METHOD:** By using the datas of ten years (2002-2011) in the 2012 Health Statistics yearbook, statistical evaluation was performed. Bed occupancy rate, bed turnover interval and bed turnover rate were compared by using Kruskal Wallis test and Mann Whitney U test and approximate length of stay of in-patients was compared by using Kolmogorov Smirnov test. **RESULTS:** Bed occupancy rate of university hospitals is statistically significantly higher than the Ministry of Health and private hospitals ($p < 0,001$). In the comparison of other two hospitals, bed occupancy rate of Ministry of Health hospitals is statistically significantly higher than the private hospitals ($p < 0,001$). There was not statistically significant difference between the three group hospitals in the comparison of bed turnover interval. In the comparison of approximate length of stay of in-patients; it is statistically significantly higher in university hospitals than the Ministry of Health and private hospitals ($p < 0,001$). In the comparison of the bed turnover rates of three groups of hospitals, there was statistically significant difference ($p < 0,01$). The bed turnover rate of Ministry of Health hospitals is higher than university hospitals ($p < 0,05$), the bed turnover rate of Ministry of Health hospitals are similar to private hospitals and the bed turnover rate of university hospitals is lower than private hospitals ($p < 0,01$). **CONCLUSIONS:** It was believed that university hospitals are dealing with different and more complicated type of patients, because of that reason; approximate length of stay of in-patients and bed occupancy rates are higher in university hospitals than the other two groups of hospitals.

P-0855**The impact of teleconsultation in the access of primary care Nephrology services**

Milena Rodrigues Agostinho, Michele Paula Pretto, Rudi Roman, Natan Katz, Erno Harzheim
Telehealth Network of Federal University of Rio Grande do Sul

Background & AIMS: One of the main issues in the Brazilian National Health System are the long waiting lists for specialist services. This can be partially explained by the lack of offer of medical consultations in some specialties. However, the weakness in management and clinical services in Primary Care (PC) play a role in this context. Telehealth is a tool with a great potential to enhance PC resoluteness and to help the referral of ambulatory consultations. These study aims to analyze the effectiveness of teleconsultations in ambulatory referrals to Nephrologists in the city of Porto Alegre.

METHODOLOGY: After analyze the main motives to referral to Nephrologists, we created guidelines to organize the ambulatory referral. The physicians at Referral Complex State (RCS) used the guideline to stablish priority criteria to the appointments and also determined teleconsultations for those motives that could not be referred according to the guidelines. A team of teleconsultant physicians from Telehealth Network of Rio Grande do Sul State (TelessaúdeRS/UFRGS) called PC providers to enquire about the real need of each referral, to support clinical practice and to guide patient's following-up in PC.

RESULTS: Between July 2014 and April 2015, 723 people referred to nephrologists had their referral resolved through teleconsultations. In those teleconsultations, 33.1% of the referrals were maintained with high priority, and 45,3% were cancelled with the agreement of PC providers. The three main motives of teleconsultations were: Chronic kidney disease (55,9%), Renal Cysts (16,3%) e Kidney stone (17,2%).

CONCLUSION: Teleconsultation is a great tool to support the organization of the referral ambulatory system. It also improves the care of people who have to wait for a specialist appointment and enhances the quality of care that should be managed in PC services. The results obtained call for a further analysis of its impact in other contexts.

Keywords: teleconsultation, referral, nephrology

P-0856**Referral guidelines and the organization of the ambulatory referral system**

Milena Rodrigues Agostinho, Josué Basso, Rudi Roman, Natan Katz, Erno Harzheim
Telehealth Network of Federal University of Rio Grande do Sul

Backgrounds & aims. There exist serious issues with the access of specialist treatments in the state of Rio Grande do Sul (RS). Over 164203 patients in the country side of the state are currently waiting for an appointment with a specialist in Porto Alegre, but the system can only offer 10296 appointments per month. The referral system is worsened by the lack of information in the referral process and by the lack of criteria access to specialized service. The Telehealth Network of RS (TelessaúdeRS) is helping to organize the waiting lists of physician specialists in Porto Alegre. **METHODOLOGY:** We have created referral guidelines to organize Primary Care (PC) referrals to specialist services in Endocrinology and Pneumology. The guidelines explain the clinical situations that should be referred to specialists and the minimum information required for ambulatory referrals. The physicians from the Referral Complex State used the guidelines to stablish priority criteria in these two specialties. They also determined teleconsultations for the motives that should not be referred according to the guidelines. **RESULTS:** From 8243 cases in the endocrinology waiting list, 5043 (61,2%) were referred to teleconsultation. The remaining cases were either accepted (presented the necessary referral criteria) or pending (lack of information). The distribution in relation to the guidelines was the following: hypothyroidism (4.9%), diabetes (28.3%), nodule of Thyroid (29.4%) and obesity (10.2%). From 2983 referred cases in Pneumology, 2273 (76.2%) were referred to teleconsultation, with the following distribution: COPD (29.8%), asthma (19.7%), change in laboratory tests (12.8%), chronic cough and dyspnea (18.8%), sleep apnea (17.1%) and smoking (1.7%). **CONCLUSIONS:** Referring protocols are a great tool to improve the quality of information and optimize the work of the ambulatory referral system. When associated with teleconsultation, they can improve access to care and create a lifelong learning environment for PC teams.

Keywords: guidelines; ambulatory referral; teleconsultation.

Cluster Management for Primary Care Centers

Neus Parellada Esquiús, Amparo Romaguera Lliso, Carme Aragó Vidal, Maria Jesus Garcia Jordan, Lluïsa Rodríguez Latre, Dolores Ramirez Tarruella, Jordi Torradabella Fabrega

INSTITUT CATALÀ DE LA SALUT; ATENCIÓ PRIMÀRIA COSTA DE PONENT, CATALONIA, SPAIN

AIM: To analyze the distribution or classification into homogeneous groups of Primary Care Health Centers (PCHC), depending on indicators of structure and activity.

METHOD: Descriptive classification into groups of 53 PCHC from Primary Care Costa de Ponent (ICS), Catalonia, Spain, with an assigned population of 1,261,888 inhabitants (December 2014).

Variables used:

-Welfare indicators: (December 2014): EQA (Synthetic indicator of quality of care, used as a clinical management standard in primary care for adult and pediatric population. Data from electronic medical records); EQPF (Synthetic indicator of quality of drug prescription, used as standard in primary care); Chronic diseases (% Clinical Risk Groups 6-7 (GRG)).

-Structure Indicators: MEDEA (deprivation index by census tract in PCHC); Population per health professionals; % of immigrant population ratio; calculated population ratio > 75 years of age.

-Activity Indicators: Visitations at the primary care center and at home per patient/year

Analysis: Descriptive and correlations analysis were performed. Many Cluster analysis with no correlated variables have been studied (Ward method with square Euclidean distance).

SPSS version 21.

Results

We used three statistically significant variables for the cluster analysis (EQA, MEDEA and patients/health professional). Finally, we get five groups, with 13, 13, 16, 6 and 5 PCHC respectively. The first group shows a high mean value of EQA, close to the mean value of patient/professional relationship and close to the mean value of MEDEA result. Group three has a good EQA level, a low patient/professional ratio and a high level of deprivation. Group five has low EQA, more patients per professional and a low level of deprivation.

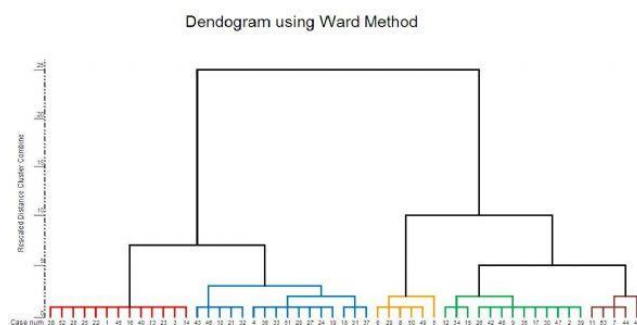

Conclusions

The PCHC are distributed into five groups according to different characteristics in the studied variables. This classification may be used for the management of the PCHC.

⁵Department of Family Medicine, KBU Karabuk Educational and Research Hospital, Karabuk, Turkey

⁶Baglar Family Practice Center, Safranbolu, Karabuk, Turkey

Background & AIM: Disabled patients are admitted to the medical board to determine the disability rate in order to use the occupational, health and social rights in Turkey. According to the law, over 40% of individuals with disabilities, based on the severity of their disability and illness rate, have different rights. We aimed to contribute to epidemiological data on people with disabilities in our country.

METHOD: Between January 2014-December 2014 the records of patients were admitted to the medical board of Training and Research Hospital, and they were analyzed retrospectively.

RESULTS: In the medical board in January 2014-December 2014, 2637 cases were evaluated. 1554 of these patients were male (59%), 1083 women (41%). With the increase of age, the frequency of application increased, too. Maximum application was in the group who are above 65 years of age. The number of cases by over 40% points are 1834 people (69%). 1055 of them were men (40%), 779 were women (29%). Average age is 45. When the cases were evaluated according to the distribution of branches, 975 cases (37%) in musculoskeletal system were identified. The least disability was in Obstetrics and Gynecology with 8 cases (0.3%).

CONCLUSIONS: Quality of life of the disabled population and the quality of services which are offered to them are closely related to the level of development of the society. In order to improve the life quality of disabled people, regional and country wide datas of these people are needed.

Assessment of the Relationship between Benign Perianal Region Diseases and Smoking Status

Nisa Çetin Kargin¹, Süleyman Kargin², Kamile Marakoğlu³

¹Department of Family Medicine, Tuzlukçu State Hospital, Konya, Turkey

²Department of General Surgery, Nusaybin State Hospital, Mardin, Turkey

³Department of Family Medicine, Selcuk University Medical Faculty, Konya, Turkey

OBJECTIVES: This study is a cross sectional study, and is aimed to evaluate the association between benign perianal diseases and smoking status.

METHOD: The study included 110 patients with benign perianal disease who were smokers, nonsmokers and quit smoking, and demanded to be treated admitted to General Surgery Clinic of Nusaybin State Hospital between April 1st, 2015 and May 1st, 2015. Health questionnaire and physical examination of the patients were performed, and a 16-item questionnaire including VAS (Visual Analogue Pain Score) scores on the first day following the operation, sociodemographic characteristics, smoking habits, comorbidities, number of operations was applied. All the data collected were evaluated by SPSS 16.0 statistics package program.

RESULTS: Of the patients admitted 78.2% were men (n=86), 21.8% (n=24) were female. 13.6% of patients (n=15) were operated from hemorrhoids, 36.4% (n=40) anal fissure, 24.5% (n=27) anal fistula, 6.4% (n=7) the anal abscess, 36.4% (n=40) anal fissure, 19.1% (n=21) were operated from pinoidal sinuses. 37.3% of patients (n=41) never smoked, 62.7% (n=69) were involved in smoking (smokers (n=45), 40.9% stopped smoking (n=24), 21.8%), respectively. The mean VAS score of the patients who never smoked was statistically significantly lower than the mean scores of the patients who were involved in smoking (smoking+quit smoking) (p=0.006). The frequency of recurrence of benign perianal disease in patients operated who were never-smokers was statistically significantly lower than of the patients involved in smoking (smoking+quit smoking) (p=0.026)

CONCLUSIONS: As a result of our study, smoking seems to have an important etiology in benign perianal diseases as in the etiology of many known diseases such as lung diseases, cardiovascular diseases and skin aging. The patients admitted to both family medicine and internal or, surgical clinics should be emphasized that smoking negatively affects the course of the disease and smoking cessation will be beneficial in the healing process.

Keywords: Benign Perianal Diseases, Smoking, Visual Analogue Score

P-0860**Evaluation of Socio-demographic and Smoking Characteristics of Patients Thinking of Quitting Smoking**

Nisa Çetin Kargin¹, Kamile Marakoğlu²

¹Department of Family Medicine, Tuzlukçu State Hospital, Konya, Turkey

²Department of Family Medicine, Selcuk University Medical Faculty, Konya, Turkey

OBJECTIVES: This study is a retrospective type of research, and aimed to evaluate socio-demographic characteristics and thoughts about smoking of the patients who applied to receive smoking cessation therapy.

METHOD: The study included 467 subjects who did not want to get medical treatment but wanted to try quitting smoking by only receiving behavioral changes therapy out of 1778 patients, who applied Smoking Cessation Clinic of Family Medicine, Selcuk University Faculty of Medicine to quit smoking between March 25, 2011- May 1, 2012. The patients were asked their health story and examined. Fagerstrom Test for Nicotine Dependence (FTND), sociodemographic characteristics, smoking related thoughts and CO (carbon monoxide) levels and Beck Depression Inventory scores were assessed. All the data collected were evaluated by SPSS 16.0 statistics package program.

RESULTS: Of the patients admitted (n=467), 84.2% were male (n=393), 15.8% (n=74) female. The mean age was 40.74 ± 11.91 (min=17, max =76), respectively. 81.4% of patients (n=380) were married. FTND average of patients was 6.26 ± 2.13 (min=0, max = 10). 22.6% of patients (BDI 17 and over) had depression symptomatology. 61.2% of patients stated that they smoked in any condition, 20.3% when nervous and demoralized. 15.0 % tried to quit smoking four or more times. 84.8% indicated that they wanted to quit because of health problems. 55.7% of the patients expressed that social environment and friend groups had influence to start smoking.

CONCLUSIONS: The success prevalence of quitting smoking with behavior modification therapy ranges between 2-5%, and this rate rises to 10-80% with medical therapy. The patients who failed with behavior modification therapy were advised to get medical treatment, and the cases with depressive symptoms were advised to receive depression therapy and their follow-up still continues. If the medical treatment costs can be met by SSI, we believe that we can be more helpful to our patients.

P-0861**Organizational Citizenship Behavior in Health Professionals of Cukurova University Faculty of Medicine**

Zeliha Akman Usguloglu¹, Esra Saatci¹, Efe Efeoglu²

¹Department of Family Medicine, Cukurova University, Adana, Turkey

²Department of Business Administration, Science and Technology University, Adana, Turkey

BACKGROUND and AIM: Organizational citizenship behaviors include voluntary behaviors of employees without any official pressure. The aim of this study is to examine the level of organizational citizenship behavior and related socio-demographic factors in health professionals of Cukurova University Faculty of Medicine.

METHODS: A socio-demographic questionnaire with 13 items and Organizational Citizenship Behavior Scale with 20 items were completed by 180 health professionals. Data was installed and analyzed using SPSS statistical pocket program version 16.

RESULTS: Of participants, 64.5% (n=100) were female and 35.5% (n=55) were male. There was a significant relationship between number of children and courtesy (p=0.0001), conscientiousness (p=0.004), altruism (p=0.005), civic virtue (p=0.0001), and sportsmanship (p=0.032). Marital status was significantly related to civic virtue (p=0.033). Occupation was significantly related to altruism (p=0.006), sportsmanship (p=0.013), courtesy (p=0.011) and civic virtue (p=0.0001). Working hours (day or night) were significantly related to altruism (p=0.002) and sportsmanship (p=0.002). The highest score was in courtesy and the lowest was in civic virtue.

CONCLUSION: Organizational citizenship behavior subscales were related to socio-demographic details of health professionals.

Keywords: Organizational, citizenship, behavior, altruism

Knowledge, Attitude and Behavior of Health Care Employees about Their Family Doctors

Fikret Merter Alanyalı, Berk Geroğlu, Yasemin Kılıç Öztürk, Yusuf Adnan Güçlü

Tepecik Education and Research Hospital, Clinic of Family Medicine, Izmir, Turkey

OBJECTIVE: Family medicine is a unique scientific discipline and a primary care oriented clinical specialty that has its own educational content, researches, evidence based and clinical practices. There are family medicine specialists(FMS) and general practitioners(GP) working at the primary care, in Turkey. In this study, health care employees' knowledge, attitude and behavior about their family doctors(FD) is intended to identify.

METHODOLOGY: The study was cross-sectional. Health care employees working at a tertiary hospital were asked to fill up a questionnaire created by researchers in November 2014. After sampling, randomisation and confirmation the questionnaire was applied face to face.

RESULTS: Two hundred and twenty-eight participants were included in the study and 72.8% (n: 166) were women, 32.5% (n: 74) were doctor, 35.5% (n: 81) were nurse and 32.0% (n: 73) were other health care employees. Participants stated that 73.2% (n: 167) know their FDs in person and 26.8% (n: 61) of them did not know. Other data about health care employees' responses and knowledge about their FDs shown in Table 1.

"Do you think that you have enough admission to your FD?" questioned and 71.9% (n:164) replied that they don't admit enough. According to answers, participants' faithfulness to their FDs about solving health problems was 54.4% (n:124) and %72.8 (n:166) participants were not going to their FDs at first if they have a health problem. As compared that if they have a GP or FM specialist, there was a significant difference ($p<0.05$) about Health care employees' attitude and behavior about their FDs has shown in Table 2.

CONCLUSION: Clinical ability and doctor-patient communication are some of the targets of family medicine specialization program. Family medicine specialization must be one of the primary goal for health policies to improve health care employees faith, knowledge, attitude and behaviour about FDs.

Keywords: Family medicine, specialization, education, residency, general practitioner

Learning from Europe – Would an alternative healthcare model benefit general practice in the UK?

Clare Wilson

Severn Deanery UK

Background

The healthcare system in the United Kingdom is based on the 'Beveridge' model of tax funding providing 'free at the point of delivery' care, delivered by the National Health Service (NHS). Alternate methods in use across Europe include the 'Bismark' model of compulsory national insurance, and other private voluntary insurance schemes (1).

The ongoing funding of healthcare in the UK is currently a subject of significant debate (2), with focus on the future of General Practice(3). This has caused concern amongst healthcare workers, who often feel a lack of representation (4).

This study aimed to identify the views of General Practice doctors (GPs) on the future of UK healthcare and possible alternate funding methods used elsewhere in Europe.

Method

An anonymous online survey was distributed via email to GPs & Doctors in training working in Bristol, and received 75 responses. This asked participants to rate 20 statements on a 5-point Likert scale from 'Strongly Disagree' to 'Strongly Agree'.

Results

There was a significant positive response ($p < 0.01$) for maintaining a 'free at the point of delivery' service based on taxation (49%), a need for change in the NHS (87%), deeming the current service cost effective (59%), and introducing fines for missed GP appointments (67%).

There was a significant ($p < 0.01$) negative response for introducing fees for GP appointments (56%), paying for healthcare up front (75%), introduction of compulsory health insurance (37%), introduction of voluntary private insurance (71%), and healthcare as a party political issue (51%).

Conclusions

This survey demonstrates a belief amongst GPs that significant change is needed in the UK healthcare system. There is support for financial penalties for missed appointments, however the majority were in favour of a taxation based, and 'free at the point of delivery' system, with significant opposition to an insurance model.

The Satisfaction Levels of Patients in Dumlupınar University Hospital

Yasemin Korkut, Ferhat Yiğit

Department of Family Medicine, Dumlupınar University, Kutahya, Turkey

AIM:

The aim of this study was to determine various aspects of both satisfaction levels and related socio-demographical variables of patients.

MATERIALS-METHODS:

This study has been done to evaluate the patients acknowledgement levels of the service and their expectations. 100 individuals accepting participate in this study have been interviewed.

In this evaluation, 100 patients were questioned with 14 different questions. We also determined some imperfection of our hospital related to maintenance services, nursing and physician-patient interactions.

RESULTS:

56% of patients were female, 44% of them were male and average age was 38,1. While 37% of the patients were waiting to take their turns, 23% of them were waiting for analysis and examination. 48% of the patients were pleased with the hospital service, 44% of them were pleased with the nurses and the other hospital personnels' behaviors and 60% were pleased with the doctors behaviours. 58 of the patients implied that the doctors gave enough information about their illnesses. This showed a meaningful relation between the satisfaction with the doctor's behaviour and the information about the illness given by the doctor. 48% of the patient group thought that satisfactorily attention was given to the patient privacy by the hospital. 40% of the patients were pleased with the sanitation and tidiness at the hospital, 42% of the patients believed that doctors did their best to diagnose their illnesses. 55% of the patients stated that they were pleased with the hospital services, 56% of them were pleased with the nurses and the other hospital personnels' behaviours, 66% of them were satisfied with the doctors' behaviours.

CONCLUSION: Patients are generally accepted as an indicator of service quality. For that reason, it is essential to take it into consideration. There is a linear relationship between Socio-economic status and patient satisfaction.

Population potentially excluded from health coverage since the Royal Decree 16/2012 and its health impact in Catalonia

Dolors Comet, Joan Pau Millet, Dolores Alamo, Lluïsa Ortega, Núria Sala, Josep Vidal
EAP Plaça Catalunya. Gerència Territorial Catalunya Central. Institut Català de la Salut. Manresa (Spain)

BACKGROUND: in order to reduce costs to the National Health System (NHS), Royal Decree -Law 16/2012 has restricted the right to health care of the immigrant population in Spain. Unauthorized foreigners or not registered as legal residents, will only receive not emergency care only if they are under 18 or pregnant women.

AIM: To determine the proportion of the population of Catalonia potentially excluded from health coverage since the Royal Decree 16/2012 (RD), to describe the use of health services, the distribution of disease and health and drug expenditures in Catalonia (2011-2013).

Design: a population based retrospective cohort study at primary care (PC).

Setting: primary care in Catalonia

Subjects: Catalonia residents assigned to the PC Catalan Institute of Health (ICS).

Variables: Sociodemographic, chronic and infectious disease, use of health services and medical expenditures variables will be studied and compiled from the Information System for the Development of Research in Primary Care (SIDIAP).

Statistical analysis: descriptive data, χ^2 test with significance level of <0.05 . Survival analysis, Kaplan- Meier curves compared by Log-rank test will be performed. At multivariate level, Cox regression and Hazard ratio with 95% CI will be calculated.

Expected RESULTS: the excluded population by the RD, has less chronic disease, are less visited in PC and emergency, they has fewer drug expenditures but increased incidence of infectious diseases.

Limitations: Even if only ICS population is included, data from SIDIAP is a good approximation of the entire population. It does not include people with incomes $>100,000$ euros/year or who have never been in contact with the health system.

P-0866

The GPs' role for encouraging blood donation based on donors' information seeking preferences

Foivos Evangelos Kakavitsas¹, Petros Kostagiolas², Anestis Chanos³, Dimitrios Niakas³

¹Health Center of Aghios Athanasios, Kerkyra - Greece

²Ionian University Kerkyra - Greece

³Hellenic Open University, Patras - Greece

Background & Aim

Blood donation (BD) is essential for every healthcare scheme; while the demand for blood increases. BD policies aim at reducing uncertainties and misconceptions regarding the alleged risks of BD. This essentially includes utilization of various channels of information for informing the communities for BD. Although internet plays a significant role people still heavily trust their physicians for health information. GPs are closely related to their patients' communities and their rather unique placement in the primary care makes them build long term relationships with their patients. This paper aims at the GPs' role for awareness and encouragement towards blood donation. This endeavor is grounded on the information seeking preferences and information needs of blood donors.

Method

The survey took place in 2014 through a questionnaire informed by Wilson's macro-model for Information Seeking Behaviour (ISB) to investigate the importance of BDs' information needs, utilization of information resources, and importance of obstacles during information seeking. A total of 352 individuals participated in this survey and the statistical analysis performed includes descriptive and inferential statistics for the group categories and associations of different categories. The questionnaire had a good internal consistency with Cronbach alpha 0.914.

Results

The results outlined the fact that the main needs for information are related to BD process; preferred information resources are GPs and the internet; while the abundance of information in the internet is the main barrier. Furthermore, certain demographic factors such as age are indicated as significant with respect to BDs' information seeking behavior preferences.

Conclusions

The research concludes that the donors' ISB facet is important and can inform policies for BD. We argue that GPs involvement is an essential condition for awareness enhancement towards BD and that GPs can guide the communities by presenting a range of online and offline trusted information resources for BD encouragement.

The Ottoman's Family Physicians: "Memleket Hekimleri" at 1871

Tarık Eren Yılmaz¹, Tuğba Yılmaz², Rabia Kahveci², Adem Özkara²

¹Department of Family Medicine, Centre of Mamak public health, Ankara, Turkey; Department of History of Medicine and Medical Ethics, Hacettepe University, Ankara, Turkey

²Department of Family Medicine, Ankara Numune Training and Research Hospital, Ankara, Turkey

Background and Aim

Family medicine is a modern discipline that provide prevention and treatment of disease. Public health also is in their subject. Early recognition of any epidemic outbreak and continuing medical care must be done with this discipline. Immunization is also another topic in their practice. Initial assessment to the management of all health problems. Family physician also must have comprehensive and holistic approach to all these situations. Family physician is primarily responsible for health services administration in their local area. In brief a total health care responsibility from the first contact to the social and environment health report must be well- managed by family physician at where they appointed.

All these definition and job descriptions were also made by Ottoman Empire at 1871 by a regulation called "İdare-i Umumiye-i Tıbbiye Nizamnamesi". At this general administration of medical regulation there was a type of provincial doctor called "Memleket Hekimi" which was very similar job description of this century's family physicians.

So we aimed to find similarity between modern family medicine practice and Ottoman's provincial physicians' approach by comparing the job definition in their official regulation.

Method

Definition and management of primary care will be compared each other in their regulations. By this we can look how the Ottoman Empire establish their primary health institutions during the 19th century.

Results and Conclusion

The study is still running and the findings are expected to be presented during the conference. The findings would be expected to give us an idea about how civilian health services were established to the Ottoman provinces and rural areas after the opening of the Civilian School of Medicine in İstanbul, how new graduates who were appointed from the center were offered compulsory service to the local region and how the policy of primary care were done.

Family medicine for universal health coverage: The case of the health transformation programme in Turkey

Ana Belen Espinosa

Centre for Global Health, Trinity College Dublin, Ireland

Background & AIM:

This study aims to recognize the improvements and difficulties in the Primary Care (PC) service encountered by Family Physicians (FP) and academicians after the implementation of the Family Medicine Programme (FMP) in Turkey. The FMP embraced changes in the organization of the PC service as well as modifications in the training of PC physicians.

METHOD:

This is a qualitative study based on semi-structured interviews analysed through thematic methodology. The purposive sample consisted of 7 family physicians working in family medicine service and 8 academicians involved in family medicine training or undergraduate education at medical schools.

RESULTS:

The themes were classified following the framework of structure, process and outcomes to approach the primary care system. In the structure level, family physicians and academicians maintained that better public recognition

of the status of the FP specialist, increased FP income, and the systematic establishment of FP functions were the positive aspects of the FMP. However, both FPs and academicians regretted that family medicine stakeholders were not invited in the whole design and implementation of the programme and that their feedback were not appropriately taken into account to overcome the difficulties encountered after the implementation. The high workload of FPs and the negative performance-based payment system were also a motive of concern. In the process level, almost all interviewees agreed that the accessibility and continuity of healthcare have improved. They highlighted the importance of the establishment of a referral chain to increase the efficiency of the service.

CONCLUSIONS:

The FMP improved the accessibility and continuity of PC in Turkey, which are essential attributes in a strong PC service. This can be enhanced by involving family medicine stakeholders in the health policy-making process and improving integration and coordination of PC in the health system to allow the implementation of gatekeeping function.

Existing Problems of Family Medicine Practice in Turkey

Müslüm Aslan

KARAHÖYÜK FAMILY HEALTH CENTER

From the date of the pilot study of family medicine, till the transition to the implementation over Turkey, adequate solutions couldn't found to the problems by the 13th December 2010. New problems were added to the old ones and many problems remain unresolved or current has continued with insufficient solution. I have observed in Family Health Center I worked actively over the last 2 years, and other family physicians and family health workers actively try to identify the personnel of voiced my problems. This is what the family medicine practice more sustainable issues, it is difficult to predict.

Detected problems

1. Precarious work, not to organize in favor of personal rights and pensions
2. With the excess workload, which is a non-criminal punishment in other occupational groups / warnings to be of points
3. Reservations due to the increased potential malpractice in the professional practice of physicians
4. Annual leave issues, the inability to use annual leave without the mandate, the attorney fee when used as cut
5. There is no administrative staff physician in the family health center to be demolished in the administration, to the work of the officer physicians
6. No borders for responsibility and mission: judicial duties, duty of family health centers, commissioning, training
10. Social Security Institution payments treatment limitations, unpaid drugs, restrictions on the branches of some drugs
90. Lossing the existing rights of family medicine specialists and education assistants

Opinion: The specified as soon as possible long-term solutions must be found for the problems. Developed in consultation with existing applications and provide quality services to workers in the field project should be carried out. The application must be made to provide better quality of service should be beyond daily politics and daily politicians. Field vision should be investigated and assessed periodically.

IKCU Atatürk Training and Research Hospital One Year Outpatient Clinic Profile

Utku Eser¹, Doğukan Doğan², Ecem Pars², Yunus Utkan², Bektaş Yılmaz², Murat Tozman², Kurtuluş Öngel³

¹IKCU Atatürk Training and Research Hospital Directorate

²Izmir Katip Çelebi University, Faculty of Medicine

³Izmir Katip Çelebi Üniversitesi, Faculty of Medicine, Department of Family Medicine

AIM: In this study, it was aimed to reveal the outpatient population and clinical profile of Izmir Atatürk Education and Research Hospital for 2014 year.

MATERIAL-METHOD: Study was performed by medical students of Izmir Katip Celebi University between March-May 2015. It was designed as a retrospective data analysis. The study population consisted of 1415770 patients who were admitted to hospital in 2014. The data were provided from the statistics unit of the hospital after the approval of the directorate. Data were analyzed by MS Excel programme by the study group.

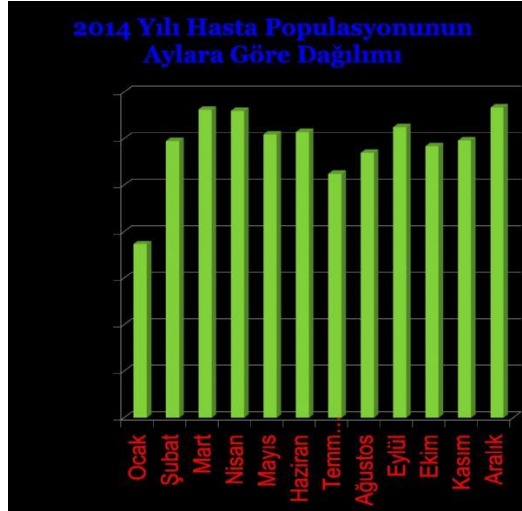

FINDINGS: Number of the patients in the scope of the study was 141577 million and 563170 people (40%) were male, 852600 (60%) were female. Maximum patient number was in december (133306) and minomum patient number was in January (74560). Applications were mostly made to the emergency medicine, internal medicine, dermatology, neurology, ear-nose-throat, physical therapy and rehabilitation clinics. Mostly encountered diagnosis were malaise-fatigue, essential (primary) hypertension, extremity pain, non-insulin dependent diabetes mellitus and pregnancy. Total 726 doctors (25 professor, 87 associate professor, 307 specialist, 307 research assistant) served health service for these patients. Mostly crowded unit was internal diseases with 60 physicians.

DISCUSSION: It can be said that Izmir Ataturk Training and Research Hospital is one of the largest hospitals according to the annual total number of inspections (n:141577 million). When we analyzed the data of 2014 patients with 60% women and 40% men; it was considered worthy of study. December was the most intensive

month related with the seasonal changes. As an expectal condition; most of the references were to the emergency department. However, the high numbers of emergency patients brings ming the abuse by non-urgent patients. Mostly encountered diagnosis were malaise-fatigue. This situation is the same in different studies so we must be alert with this diagnosis.

Latest Two-Year Analysis of Patients Applied to Prisoners Policlinic

Utku Eser¹, Merter Alanyalı², Kurtuluş Öngel³

¹İKÇÜ Atatürk Education and Research Hospital Directorate

²İzmir Tepecik Education and Research Hospital, Clinic of Family Medicine

³İzmir Katip Çelebi University, Department of Family Medicine

AIM: Related with the opinion that most of the prisoner patients in a third step hospital can be diagnosed and treated with primary care doctors; this study was designed to detect the situation and investigate the factors that vary between years.

METHOD: This retrospective study, aimed to determine the diagnosis of patients admitted to the prisoner department, was performed with 34130 patients who were admitted to Izmir Katip Celebi University Atatürk Education and Research Hospital within 2014 and the first 7 months of 2015.

FINDINGS: When the diagnoses were examined; 11403 (33.4%) were of interest to primary care patients and the most common diagnosis was [7845 (68.7%)] pain (muscles, joints, etc.). Other diagnoses in order of frequency were; porter inspection, hemorrhoids, gastritis, malaise-fatigue, seasonal allergies, cystitis, dizziness, anemia, acne vulgaris, cough, constipation and respiratory tract infections. In 2014 year, 21897 patients and in the first 7 months of 2015 12233 patients; about 100 patients per day were inspected. When diseases related with primary care were investigated; monthly rankings were not variable but according to years porter examination in 2015 was 271 (4.2%) patients, while it was 608 (12.1%) for 2014, nearly three-fold increase.

RESULTS: Prisoners clinics were places, established for the convenience of the enforcement personnel and medical personnel protection. However, around 100 patients per day has been shown to be examined. These patients, if it continued, can not be evaluated under appropriate conditions. However, many patients may be treated in the first step (prison family physician). We anticipate that such patients can be directed to family physicians and health care burden can be reduced in order to provide tertiary health services in appropriate conditions.

An Innovative Interprofessional Education Course at Eastern Virginia Medical School

Jeffrey Allen Johnson

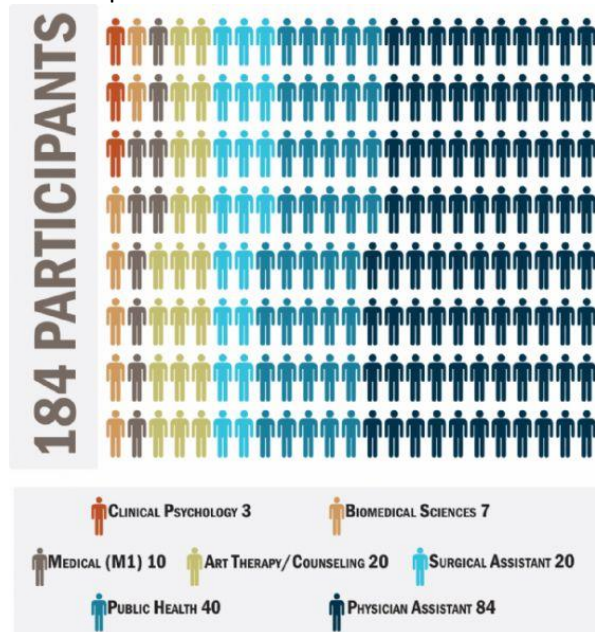

Eastern Virginia Medical School

Eastern Virginia Medical School (EVMS) is an academic health center dedicated to achieving excellence in medical and health professions education, research and patient care. EVMS enrolls ~1300 students in 13 degree programs based within our School of Medicine and School of Health Professions. During this academic year we are implementing a 1-credit interprofessional education (IPE) course involving 200 students from 8 diverse disciplines including medicine, physician assistant, surgical assisting, art therapy, clinical psychology, public health, and biomedical sciences. Students convene for six 2-hour sessions using didactic and case-based learning combined with breakout sessions for 20 groups of 10 students each. Each session has learning objectives and assigned readings that correspond with four major competency domains: values/ethics, professional roles, communication, and teamwork. Case topics include an overview of TeamSTEPPS, diabetes, cancer, Alzheimer’s Disease, sexually transmitted diseases, and epidemics.

Each session is guided by an expert presenter, and the topics are explored from a research, patient care, and population health perspective. Faculty members from multiple backgrounds facilitate the small groups. Formative and summative evaluation protocols are used to assess student and faculty perceptions of each session and the overall value of the course. Students will also complete a pre- and post-test documenting their knowledge and views about IPE. Next year we will add 150 first-year medical students to the course, and possibly students from other schools in the future. Our goal is to ensure that students have exposure to and meaningful engagement with their peers in other programs/disciplines. If successful we may attempt to expand the course to a regional model that will include multiple universities that offer graduate level health professions education, and possibly to the region's primary community college.

C Course Competencies

COURSE COMPETENCIES

VALUES & ETHICS

Work with individuals of other professions to maintain a climate of mutual respect and shared values.

ROLES & RESPONSIBILITIES

Use the knowledge of one's own role and those of other professions to appropriately assess and address the healthcare needs of the patients and populations served.

COMMUNICATION

Communicate with patients, families, communities, and other health professionals in a responsive and responsible manner that supports a team approach to the maintenance of health and the treatment of disease.

TEAMS & TEAMWORK

Apply relationship-building values and the principles of team dynamics to perform effectively in different team roles to plan and deliver patient/population-centered care that is safe, timely, efficient, effective and equitable.

Digital Poster

School of Health Professions
Interprofessional Collaborative Education (ICE)

DEFINITION
Interprofessional education (IPE) is the process by which students from two or more professions learn about, from, and with each other to enable collaborative practice to improve or develop health care for the population.

BACKGROUND
The School of Health Professions at Eastern Virginia Medical School is committed to interprofessional education and collaborative practice. This program is designed to provide students with a collaborative and interdisciplinary approach to learning.

2015-2016 COURSE TOPICS

- UNCONSCIOUS BIAS & CULTURAL COMPETENCIES
- VALUES & ETHICS
- COMMUNICATION
- PERSONALITIES, TEAMS & LEADERSHIP
- PATIENT SAFETY & ADVOCACY

COURSE COMPETENCIES

- VALUES & ETHICS**: Work with individuals of other professions to maintain a climate of mutual respect and shared values.
- ROLES & RESPONSIBILITIES**: Use the knowledge of one's own role and those of other professions to appropriately assess and address the healthcare needs of the patients and populations served.
- COMMUNICATION**: Communicate with patients, families, communities, and other health professionals in a responsive and responsible manner that supports a team approach to the maintenance of health and the treatment of disease.
- TEAMS & TEAMWORK**: Apply relationship-building values and the principles of team dynamics to perform effectively in different team roles to plan and deliver patient/population-centered care that is safe, timely, efficient, effective and equitable.

STRUCTURE & FORMAT

- Students will receive 1 credit hour.
- Each year will have different learning objectives and topics, and be delivered in various formats.
- Students will receive 1 credit hour of CEU credit for this program.

Medical students' knowledge and concerns regarding sports doping: An observational study

Lana El Osta, Hassan Tarhini, Nazek Saadallah, Nada El Osta

Department of Public Health, School of Medicine, Saint-Joseph University, Beirut, Lebanon

BACKGROUND AND AIM: Doping in sport is a large and dangerous phenomenon. It is often undetected by physicians, and its complications ignored by young people. This study aimed to explore the level of knowledge of Lebanese medical students regarding sports doping.

METHODS: An observational cross-sectional study was conducted at a major Lebanese medical school in 2013. Data were collected through an anonymous structured self-administered questionnaire distributed to all medical students (n=579). This questionnaire assessed participants' knowledge in 5 areas of sports doping: its definition, magnitude and negative effects, as well as prohibited performance-enhancing substances and types of population affected by doping.

RESULTS: A total of 505 valid responses were obtained generating a response rate of 87.2%. Only 5.5% were absolutely unaware of doping. The overall level of knowledge on doping was relatively modest: the mean score of all respondents was 20.23 ± 7.51 ; while 56.9% had a global score more than 20 over 40. According to the multiple regression analyses, factors significantly associated with a higher score were: higher medical classes (-p-value<0.0001), participation in national competitions (-p-value=0.022), participation in competitions of sport clubs (-p-value=0.040), and having been asked to provide information on doping (-p-value=0.044). Moreover, most medical students (89.3%) did not know the meaning of WADA (World Anti-Doping Agency); 85.7%, 88.9% and 93.9% considered respectively that vitamins, energy drinks and proteins are prohibited performance-enhancing substances. Anabolic steroids and stimulants were the most recognized illicit drugs. Only 25.2% of participants were satisfied with their knowledge, while 61.2% were concerned about sport doping prevention. The majority (90.1%) considered that primary care physicians are actors in the field of anti-doping activity.

CONCLUSIONS: Our study revealed a deficient knowledge regarding sports doping among Lebanese medical students who are interested in anti-doping counselling. Thus, professional training strategies to increase their awareness and knowledge are required.

Keywords: Sports Doping, Performance-Enhancing Substances, Medical Students, Knowledge

Medical students' knowledge regarding sports doping (N = 505 participants)

1. Definition of sports doping (7 items)	Percentage of correct answers
- Is the use of certain chemical substances or of methods	84.6%
- Improves athletic performance	76.8%
- Is used to prepare the athletes to win	63.6%
- Is dangerous to the athletes' mental health	66.9%
- Is dangerous to the athletes' physical health	83.2%
- Is unethical and immoral	77.4%
- Is prohibited	69.1%
2. Magnitude of sports doping (4 items)	
- Is a large and universal phenomenon	68.7%
- Is a public health problem	60.8%
- Most record-breaking performances are achieved through doping	24.8%
- Doping affects all type of sports	53.1%
3. Prohibited performance-enhancing substances (15 items)	

- Anti-estrogenic substances	34.7%
- Alcohol consumption	50.9%
- Beta-2 agonists	29.1%
- Beta-blockers	14.3%
- Energy drinks	11.1%
- Caffeine	15.6%
- Diuretics	12.7%
- Hormones (EPO, GH, corticosteroids,..)	62.4%
- Narcotics such as morphine	24.8%
- Manipulation of blood or blood components	21.0%
- Proteins	6.1%
- Anabolic androgenic steroids	74.5%
- Stimulants (Adrenaline, amphetamine,..)	73.3%
- Red meat	28.1%
- Vitamins	14.3%

4. The negative effects of sports doping (6 items)

- Addiction	79.0%
- Excessive aggression	62.0%
- Osteo-articular injuries	50.1%
- Cardiovascular complications	83.8%
- Depression	62.2%
- Death	69.3%

5. Population affected by sports doping (8 items)

- Champions/professionals	85.3%
- Amateurs	57.2%
- Adults	57.4%
- Adolescents	74.3%
- Children	6.5%

³School of Nursing and Midwifery, Griffith University, Meadowbrook, Australia

⁴Discipline of General Practice, University of Newcastle, Callaghan, Australia

BACKGROUND: Antibiotic resistance is a public health concern worldwide. A high proportion of antibiotics are prescribed in primary care, often for conditions where there is no evidence of benefit. Without a change in these prescribing patterns, resistance will persist as a significant problem. Educational interventions have had limited effect. Targeting early-career doctors while their habits are developing may be a more effective strategy. Many studies have investigated the antibiotic prescribing habits of established family doctors, but little is known about how trainees perceive and develop their prescribing.

AIM: To explore the attitudes of trainees in family practice towards antibiotic use and resistance, and the perceived influences on their prescribing.

METHOD: A qualitative study employing semi-structured interviews and a focus group. Seventeen trainees in family practice were purposively sampled from rural and urban locations in Australia, aiming for maximum variation of participants. Topics of discussion included awareness of antibiotic resistance, use of evidence-based guidelines and perceived influences on prescribing decisions. Sampling continued until thematic saturation was achieved. Data collection and analysis were concurrent and cumulative, using a process of iterative thematic analysis.

RESULTS: Trainees were aware of the importance of evidence-based antibiotic prescribing and the potential impact of their decisions on antibiotic resistance. They held generally positive attitudes towards the use of guidelines. The context of prescribing influenced their decisions, including patient and system factors, diagnostic uncertainty, transitioning from hospital medicine to primary care, and the habits of, and relationship with, their supervisor.

CONCLUSIONS: Understanding why trainees prescribe antibiotics and how their habits develop will be of utility to those involved in the training of family doctors. Our results are informing the development of an innovative educational intervention promoting rational prescribing, addressing the important issue of antibiotic resistance by targeting a new generation of prescribers.

Keywords: antibacterial agents, drug resistance microbial, graduate medical education, physician prescribing patterns.

Antibiotic resistance is a public health concern worldwide

Australia

Interview quotes: trainee prescribing

I just don't want to be contributing to the over-prescribing of antibiotics for viral URIs that will clear on their own.
I just don't want to perpetuate it, but I do.

Why do trainees prescribe antibiotics for self-limiting respiratory tract infections?

Patient and System Factors
 Demographics
 Access to care
 Local disease patterns
 Perceived patient pressure

Transition to Primary Care
The majority of people [with respiratory infections] who are in hospital end up on antibiotics...when I first started I was a little bit more likely to give antibiotics coming out of that situation.

Diagnostic Uncertainty
I think early on I was really hesitant about it and thought "I probably shouldn't be giving antibiotics here but they look sick and they always get them." Whereas now I think I'm a lot more confident to say, "No, you don't need antibiotics."

Interview quotes: supervisor influence

How do supervisors influence evidence-based prescribing?

Providing a good precedent
 Education
 Role-modelling
 Trust and respect

The supervisor has been practising for at least 30 years and is very experienced. So when he tells me something I usually believe it.

Patient expectations
 Overt pressure

My supervisor will give his patients antibiotics even for something that sounds very viral, and therefore when I see his patients, I feel I'm expected to do that as well...I'm definitely more likely to give his patients antibiotics even when I don't think it's justified.

P-0876

The Fundamental Teaching Activities Framework for Teachers in Family Medicine: a new tool for teachers and programs

Allyn Elizabeth Walsh

College of Family Physicians of Canada

Background and Aim

The College of Family Physicians of Canada recognized the importance of supporting teachers as new competency-based curricula were adopted nationally. Teachers need both a clear understanding of the expectations and opportunities within their roles and faculty development to guide their professional growth. Educational institutions need direction in developing and organizing curricula and resources to support this professional development.

Method

A fundamental teaching activity is defined as a holistic description of what a teacher actually does, and includes a number of different competencies. A framework articulating the fundamental teaching activities of teachers in family medicine settings was developed based on the concept of Entrustable Professional Activities (EPAs). Beginning with a literature review, and moving through an iterative process including teachers, faculty developers, program leads, residents, and medical students, three domains were described: Clinical Preceptor; Teacher Outside the Clinical Setting; and Educational Leader. Within each domain, several tasks were identified, each broken down into several fundamental activities. A developmental trajectory consistent with the Euract Framework for CEDin GP was described for each activity, permitting teachers to identify next steps in their professional development.

Results

The Framework was well received by the reviewing groups of teachers, program leaders and faculty developers.

Teachers were able to quickly identify with the Fundamental Teaching Activities. Departments/Programs in Canada have begun to use the Framework in faculty development.

Conclusion

A framework of teaching activities, based on the concept of EPAs for learners, is being launched by the College of Family Physicians of Canada. The concept of Fundamental Teaching Activities (FTAs) is intuitive for teachers and useful in understanding teacher development and in planning faculty development activities.

Keywords: Teachers, continuing educational development, EPAs for teachers

Elderly Fall Prevention: risk factors and health promotion identification

Ana Rosa Murad Szpilman, Danilo Dos Santos Pianca, Carla Thiebaut Jussim Kalil Silva
Department of Public Health, Vila Velha University, Vila Velha, Brazil

BACKGROUND & AIM

Falls are a really common and devastating event for elderly people. It can indicate a beginning of an illness or signalize a weakness, besides increasing the health system costs. It is hard to prevent because it can present a variety of predisposing factors. However, simple measures can corroborate to falls prevention and health promotion. The aim of this study is to present elderly falls main risk factors and preventive measures, and to promote necessary adjustments in their homes for better quality of life.

METHOD

The Vila Velha University Medical students performed an educational Speech for 20 elderly people in a Public Health Unity, in Brazil, providing information about the main falls risk factors, as well as, physiological changes related to senility and how to handle them. Preventive measures Illustrations and explanations were presented and afterwards a checklist was used to identify the risk factors on the participants' residences.

RESULTS

50% of the elderly people presented at the speech have already suffered some kind of injury caused by avoidable falls. Among the main causes of falls, 40% were related to postural hypotension, 30% to use of inappropriate shoes, 20% to fall during taking a shower and 10 % to associated comorbidity, such as labyrinthitis. Notice that 90% did not practice any physical activity.

CONCLUSIONS

The elderly population in Brazil has been increasing each year, impacting the assistance offered by the public health system services. The elderly population life expectancy has been growing along their active participation in society. A fall can be decisive in a senior autonomy rupture, intervening directly to his quality of life and dependency level. The risk factors identification using the checklist facilitated the performance of the Community Health Workers in the process of environmental adaptation, ensuring the elderly people more security and life quality.

Teaching-Service experience: Medical students from Federal University of Grande Dourados, family health teams of Dourados city and Telehealth Brazil Program

Crhistine Cavalheiro Maymone Gonçalves¹, Adélia Delfina Da Motta Silva Correia², Leonardo Cançado Monteiro Savassi³

¹Faculty of Health Sciences, Medicine, Federal University of Grande Dourados

²Faculty of Medicine, Federal University of Mato Grosso do Sul

³Faculty of Medicine, Federal University of Minas Gerais and Federal University of Ouro Preto

Background & AIM: This is a teaching-service-community experience with 40 medical students and 11 family health teams of Health Department of Dourados city and its partnership with the Scientific-Technical Core of Telehealth Brazil Networks Program in Mato Grosso do Sul (MS), linked by the State Department of Health (SES-MS).

METHOD: During the first half of 2014, by discipline of Community Health, students and teams experienced the work of applying the Family Risk Scale of Coelho-Savassi (ERF-CS), a brazilian instrument of family stratification risk, that takes into account vulnerability, based in sentinels of risk collected by family health team while visiting families. Datas were collected and recorded on a form called Record A, part of Primary Care Information System (SIAB). The experience was aimed at learning, research and assistance to implement actions to families. The knowledge of the reality of territory, identify the watchmen of risk and support the planning of home visits were targets. There were field research activities, interspersed with web conferencing and Virtual Environment Moodle Learning via Telehealth, important educational vehicle distance, which made the communication between the teams and teachers who supported the experience.

RESULTS: The differential of this deployment was the movement of integration of teams and students that enabled the identification of the vulnerable situation of 11,812 families ascribed to units. It is essential establish mechanisms to strenghten relationship between health teams and health students. It is necessary improve digital inclusion.

CONCLUSIONS: It was an innovative experience, considered satisfactory with essential results to boost new experiences in medical education through teleducation, aimed at integrating teaching and service-community and, consequently, increasing supply and access to teleassistance actions and teleducation, strengthening primary health care-APS as the coordinator of care and the Health Care Network. This experience is also being registered in two books in press.

Nutrition and Medical Students' educational activity: hypertensive and diabetic patients' improvement on interest and adherence to lifestyle changes

Ana Rosa Murad Szpilman, Tayná De Souza Melo

Department of Public Health, Vila Velha University, Vila Velha, Brazil

BACKGROUND & AIM

The Vila Velha University medical students participate in a curricular internship in the public health unities. Since the beginning, the students attend the Federal Government HiperDia Program, which monitors the hypertensive and diabetic patients assisted by the Health Unity. The meetings occur once a month, with awareness, blood pressure and glucose follow-up. The medical students insist on persuading patients to lifestyle changes. After one year and a half, participating in these meetings, discussing the same subjects over and over again, despite the methodology changes, some students bothered with the monotonous and not persuasive way of trying to create patients' awareness. Therefore, they decided to invite the nutrition students to show, in a dynamic and contextualized way, the nutritional interference on hypertension and diabetes.

METHOD

The nutrition and medical students with their teachers organized a health nutrition workshop in the community church, in which they showed the 30 hypertensives and diabetics presented, the quantity of salt and sugar found in some common foods, using known measures like spoons, glasses and recipients.

RESULTS

It was visible in the patients facial expressions the impact caused by the quantity of salt and sugar shown in the variety of foods presented. Distinctly from the usual reactions with the lectures and speeches performed by the students before, the patients demonstrated enthusiasm on trying to experience some lifestyle changes related to nutrition health.

CONCLUSIONS

Lifestyle changes are a real challenge for health professionals on treating their patients. This workshop shows that working in a team facilitates achieving success on improving patients' quality of life. Different approaches may bring better results when the objective is to work with health education and preventive assistance. Putting in place educational activities with students from different health graduation courses may increase the results in lifestyle changes achievements.

Men's Health Care Educational Activity: prevention and self-care awareness

Ana Rosa Murad Szpilman, Tayná De Souza Melo

Department of Public Health, Vila Velha University, Vila Velha, Brazil

BACKGROUND & AIM

The Vila Velha University medical students participate in a curricular internship in the public health unities, putting in practice a variety of activities, creating a favorable environment to put in action all the theoretical content they are studying in the university, benefitting the professionals and the assisted community. It is well known the invulnerability myth attributed to male figure, which ends up damaging their self-care, harming serious illness early diagnosis. In order to sensitize men assisted by the Health Unity, the students promoted a meeting called "an afternoon chat with men" to create a self-care awareness on the assisted men by the public Health Unity.

METHOD

During the meeting "an afternoon chat with men", the students discussed several themes: the risks of routine appointments indifference, prostate cancer, body hygiene, condom correct use, and other subjects suggested by the participants. The female students prepared a health snack, received the participants, and checked their blood pressure and glucose level. The male directly participated in the meeting.

RESULTS:

The participants exposed themselves in an unexpected way, asked a lot of questions, cleared their doubts, and committed on taking better care of their health, seeking for help in the health unity whenever they feel sick or in need of help. The male invulnerability myth was demystified to avoid self-care obstacle. After the meeting, the students noticed an increase on male search for professionals' assistance in the Health Unity.

CONCLUSIONS:

The students attitude on creating this space for men to talk about their health and masculinity was acknowledge by the health unity professionals and the assisted community as a health promotion space, helping the professionals with their daily work in the unity. The idea is to transform this one meeting "an afternoon chat with men" into a continuous project in the unity.

Young Doctor Movement at WONCA World Rural Health Conference 2015 – Involvement and Outcomes

Veronika Rasic¹, Ivana Babic¹, Kyle Hoedebecke², Victor Ng²

¹Vasco da Gama Movement

²Polaris, WONCA YDM

BACKGROUND: The WONCA World Rural Health Conference will be held in Dubrovnik, Croatia in April of 2015. The organizing committees decided to include the involvement of junior doctors and students to help promote rural practice and present it as an attractive career choice. The WONCA young doctor movements rose to the challenge and will be presenting a number of workshops and papers at the conference. We would like to share with you the outcomes of our activities. Subjects that will be covered include: leadership in healthcare, quality improvement in practice, obstacles to recruitment and retention of junior doctors in rural practice, differences in rural practice around the world, student involvement in rural health, the image of rural healthcare and many more.

METHODS: Information will be gathered from the participants of the workshops and presenters/facilitators.

RESULTS: Promoting rural practice in the junior doctor and medical student community. Providing a platform where they can ask questions and share their opinions.

CONCLUSION: The goal is to promote rural practice as a career choice among medical students and young doctors and attempt to address issues that are presently making this a challenge. We hope that the outcomes of our contribution at this conference will help to include junior doctors and students in rural practice and provide a platform that encourages contributing to possible solutions to obstacles. The poster will give a summary of the outcomes of the conference.

Empathy Levels and Affecting Socio-Demographic Characteristics Of Medical Students

Mustafa Gökhan Şen, Mehtap Kartal, Nilgün Özçakar

Department of Family Medicine, Dokuz Eylul University, Izmir, Turkey

Background & AIM:

Empathy in general, "put oneself instead of someone else", when a little more clarification "a mental process including appropriate understanding another person's emotional state and perspectives" is defined. Physician candidates should have the talent not only to carry out the medical part but also the medico-social part of the patient-physician relationship.

METHOD:

This study was completed by 688 Medical Faculty (1st year: 315, 3rd year: 256, 4th year: 258, 6th year: 162) students of Dokuz Eylul University in 2012-2013 academic year. A questionnaire containing socio-demographic characteristics of the students and statements concerning the patient-physician communication with The "Jefferson Scale of Physician Empathy" (JSPE) student version was used. JSPE consists of three subscales called perspective taking, to act with compassion, wearing patient's shoes. Its score ranges between 20-140 and high scores indicate high empathy. Student's t test, ANOVA, Pearson's chi-square tests were used and $p < 0.05$ was considered as statistically significant.

RESULTS:

Of the participants 54% were male and the mean age was 21.1 ± 2.1 . The total mean score of JSPE was 101.5 ± 15.3 and mean for subscale of perspective taking 51.9 ± 9.7 , for subscale act compassionately 37.8 ± 7.8 and subscale wearing patient's shoes were found 8.3 ± 2.7 . The 6th year students' scale and subscale scores were low compared to other years. Female students had higher levels of empathy except the wearing patient's shoes subscale. The

level of empathy for students living at dorms was significantly higher than the other groups, except the subscales act compassionately and the wearing patient's shoes. Students of middle-income level had high levels of empathy except the wearing patient's shoes subscale.

CONCLUSIONS:

Medical education in addition to medical knowledge has to cover the medico-social dimension of human relations that affects the patient-physician relationship positively. Increased awareness of empathy, adequate share in the curriculum will enlighten the future physicians' perspectives.

Medical Education And Advanced Technology Applications

Adem Parlak¹, Nehir Parlak²

¹Department of Family Medicine, President Guard Regiment, Ankara, Turkey

²Department of Dermatology, Etimesgut Public Hospital, Ankara, Turkey

INTRODUCTION: Because medical education is a long-term, difficulty of the curriculum and different perception levels of student, revision has been brought up for medical education. In this presentation, we aimed to increase awareness of academic members about application of advanced technology and medical education..

DISCUSSION: By the time problem-based, patient-centered, community-oriented training programs has emerged besides traditional education. After medical curriculum and technology had developed, medical education got through a new period. Thus, the students are adjusted to the health care system easier and faster. As patients become increasingly concerned that students and residents are practicing on them, clinical medicine is becoming focused more on patient safety and quality than on bedside teaching and education. Educators have faced these challenges by restructuring curricula, developing small-group sessions, and increasing self-directed learning and independent research. Nevertheless, a disconnect still exists between the classroom and the clinical environment. Many students feel that they are inadequately trained in history taking, physical examination, diagnosis, and management. Medical technologies have been proposed as a technique to bridge this educational gap.

CONCLUSION: a major challenge for medical undergraduates is the application of theoretical knowledge to the management of acutely ill patients. Students must learn to be systematic in their approach to a problem, and develop skills appropriate to working with a clinical team. However, opportunities for students to develop these attributes are limited in undergraduate training. Advanced technology applications can help them achieve these goals.

Knowledge and attitudes toward Family Medicine at the second year of the degree and election of specialty

Maria Candelaria Ayuso¹, Francisco Escobar¹, Jesús López Torres¹, Julio Montoya¹, Juan Manuel Téllez², Arancha Romero³, Juan Miguel Armero⁴

¹Albacete Area IV Health Centre, Health Care Service of Castilla-La Mancha, C/Seminario 4, 02006 Albacete, Spain.

²Albacete Area V Health Centre, Health Care Service of Castilla-La Mancha, C/, Profesor Macedonio Jinénez s/n, 02006 Albacete, Spain.

³Villarrobledo General Hospital, Health Care Service of Castilla-La Mancha C/ Miguel de Cervantes s/n, 02600 Villarrobledo (Albacete), Spain.

⁴Balazote Health Centre, Health Care Service of Castilla-La Mancha, C/Cervantes 1, 02320 Albacete, Spain.

Background & Aim

A cold climate towards primary care (PC) in the medical academia would constitute a barrier to choosing Family Medicine (FM) as a career option. This study was designed to determine medical students' knowledge of and attitudes towards FM at the second year of the degree predicts the election of FM as career.

Method

This is a cohort study. Before taking a course in PC in 2007-2008 and 2008-2009 academic years, 159 2th students were asked to respond to the brief CAMF (Spanish acronym for "Knowledge and Attitudes towards Family Medicine"), a questionnaire with 21 closed response items (5 options on a Likert scale). All of them were investigated about the election of specialty in 2013 and 2014, based on the information provided by the Ministry of Health in its web.

Statistical analysis was performed with SPSS 17.0: comparison of proportions (chi square) and means (Student t test).

Results

The mean age was 19.2 years (SD:0.88), ranging from 18 to 28 years;78.0% were women. The specialty chosen was known in 139 students:17 (12.2%) chose FM,17 pediatrics,11 internal medicine,10 gynecology, 35 internal medicine specialties, 31 other surgical specialties and 18 others.

Before starting the PC course 30.8% of students said they would like to become a family doctor in the future;58.8% for those who chose FM, significantly ($p=0.01$) bigger than 25.4% for the others. But only 4.3% considered it to be their first career choice (no statistical differences between both groups).

The brief CAMF score range was -3 to 31 (mean:16.4; SD:6.2). Graduates who chose MF had mean 19.2 (SD:6.1), significantly higher than the 15.8 (SD:6.1) of the others ($p=0.037$).

CONCLUSIONS:

Family Medicine is a minority option as specialty. Those who choose MF score higher in the CAMF, so this could be a predictor of choice of specialty.

Keywords: Family Practice; Health Knowledge, Attitudes, Practice; Students, Medical

The specialty chosen was known in 139 students:

Students saying "I would like to become a family doctor in the future", before starting the course:

Students saying "I would like to become a family doctor in the future", before starting the course:

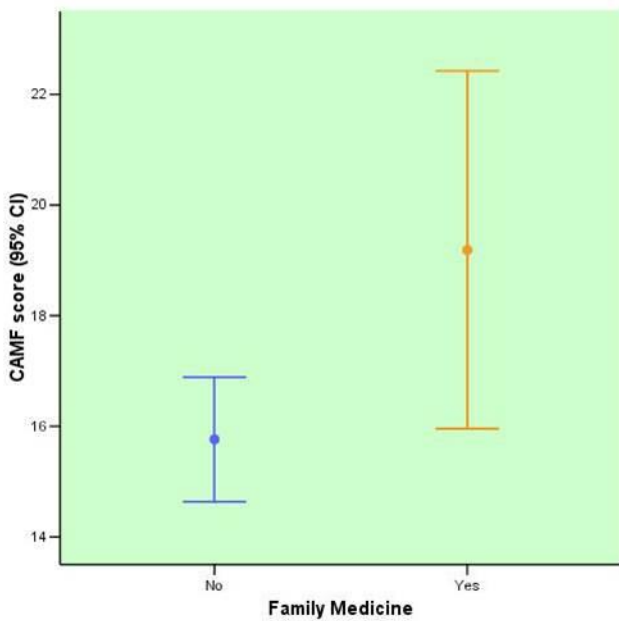

p=0.01

Students saying "I would like to become a family doctor in the future", before starting the course:

Only 4.3% considered it to be their first career choice; no statistical differences between both groups.

The brief CAMF score range was -3 to 31 (mean: 16.4; SD: 6.2). Graduates who chose MF scored significantly higher than the others (p=0.037).

P-0885

Women's Delivery of care Project: breastfeeding, self-care and newborn attention intervention experience in a maternity in Brazil

Ana Rosa Murad Szpilman, Elaine Caliman Vergna, Karem Cristina Martins Pires, Mônica Barros De Pontes, Patrícia Caldeira Penna Giesbrecht, Trícia Guerra E Oliveira
Department of Public Health, Vila Velha University, Vila Velha, Brazil

BACKGROUND & AIM

Breastfeeding is a process of deep mother and child involvement, capable of improving the baby's nutritional state, developing many benefits for both mother and child. In Brazil, the Health Ministry preconizes the exclusive breastfeeding until the baby completes six months of life, and complementary up to two years old or more. The aim of this experience was to stimulate breastfeeding and helping the mothers through this difficult time, teaching them to breast feed, and how to take care of themselves and their newborn.

METHOD

The medical students through the Health Attention Network/Stork Network PET-Health, developed by the Health Ministry, in the Pro-matre Maternity in Vitoria, Brazil, developed an intervention experience to stimulate breastfeeding and helping mothers to go through this moment with calm and tranquility. The intervention took place from August to December 2014. The methodology was based on structured observation, medical records analysis and participation on the multiprofessional health workers team activities, before performing the intervention with the women.

RESULTS:

When the students with the health professionals visit the women who have recently given birth and were breastfeeding in their rooms, after explaining what procedure would be done, they were very receptive to the orientations on breastfeeding, self-care and newborn special cares. After the intervention, the mothers were a lot more comfortable with breastfeeding, and taking care of their babies. It was notorious the improvement of breastfeeding knowledge and mother's confidence, showing that patients and health professionals trustful bond can be effective on delivering quality health care.

CONCLUSIONS:

This experience showed the students that they have an important role in the patient's life, contributing to a Medical formation that emphasizes the patient-professional bond, humanized delivery of care, responsibility to the patient's quality of life, and commitment to a responsible, professional, ethical and humanizing practicing of medicine.

How familiar with the new inhalers is our Primary Health Care staff?

Laia Gené Huguet, Amparo Hervás Docón, María Ortega Carmona, Cristina Blánquez Moreno, Nora Selvi Miralles, Núria Sánchez Ruano

CAPSBE Borrell, Barcelona, Spain

AIM

To evaluate health care professionals' familiarity with new inhalers available, ability to demonstrate them to patients and knowledge of adverse effects.

MATERIALS AND METHODS

Descriptive study in an urban primary health center with 32 professional staff (19 doctors (59.4%) and 13 nurses (40.6%)). Questionnaire distributed to all staff. Variables: sex, age, professional level, knowledge of inhaler types and their names (before 2004: pressurized cartridges (ICP), chamber, turbuhaler, accuhaler, handihaler, easyhaler; after: breezhaler, respimat, genuair and nexthaler), and their prescription. Other variables: demonstration methods (written instructions, instructional video, practical demonstration by staff), information given regarding administration order if using more than one medication, knowledge of adverse effects.

RESULTS

Median age: 42.6 ± 10.9 SD, 87.5%female. Most familiar and prescribed inhaler types: ICP and chamber (100%), accuhaler 30(93.8%), turbuhaler and handihaler 29(90.6%). Staff recognizing ICP and chamber, only 20 (62.5%) and 30 (93.8%) respectively, associating the name. Lesser recognition of breezhaler 12(37.5%), respimat 11(34.4%), nexthaler 6(18.8%) and easyhaler 8(5.15%); furthermore easyhaler was not recognized by nursing staff. 79.6% of nurses provided written information, compared to 15.8% of doctors. 92.3% of nurses demonstrated techniques, against 36.8% of doctors. The most prescribed inhalers among non-elderly patients: ICP 8(42.1%) and turbuhaler 7(36.8%), and elderly: ICP with chamber 11(57.9%). Over half (53.1%) the staff didn't know the administration order of the different nebulized medications. Those who did recommended them correctly (40.6%). The most known adverse effects were oropharyngeal candidiasis from corticoids(78.9%), mouth dryness from anticholinergics(42.1%) and tachycardia from beta-adrenergics(84.2%); more familiar to doctors than nurses.

CONCLUSIONS

Unfamiliarity of newer inhalers was evident. Practical use of inhalers was more widely explained by nurses and adverse effects were more known by doctors. In order to increase knowledge, prescription, appropriate demonstration and awareness of secondary effects we need to educate the professional staff via workshops.

Bridging the research-practice gap: The success of the Veterans' MATES program in improving medication use in veterans with musculoskeletal pain

Amanda Barnard¹, Lisa Kalisch Ellett², Mhairi Kerr², Marie Iannos², Kerrie Westaway², Elizabeth Roughead²

¹Medical School, Australian National University, Canberra, Australia

²Quality Use of Medicines and Pharmacy Research Centre, Sansom Institute, School of Pharmacy and Medical Sciences, University of South Australia, Adelaide, Australia

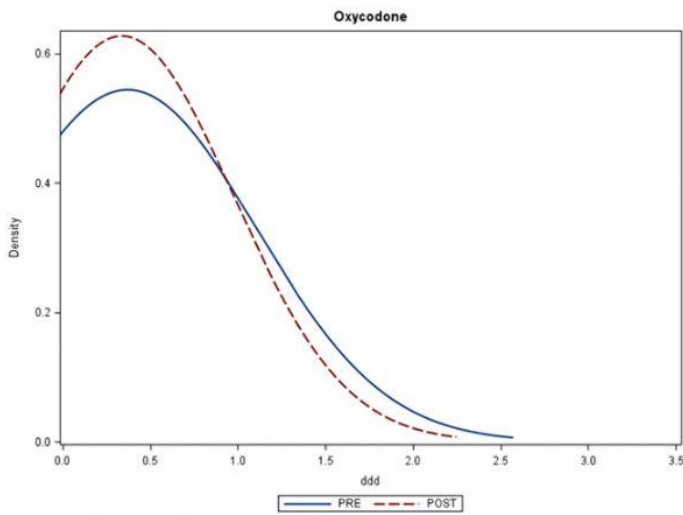

Background & AIM: The Veterans' Medicines Advice and Therapeutics Education Services (MATES) program engages General Practitioners to improve medicine use for veterans. The Australian Government Department of Veterans' Affairs administrative claims data are used to provide patient-based prescriber feedback to GPs. This is supported with evidence-based, peer-reviewed educational material developed by a clinical panel and overseen by a nationally representative editorial committee. This study evaluated the impact of the intervention that aimed to improve the management of chronic musculoskeletal pain by reducing the use of long-term opioid analgesics. **METHOD:** Educational materials included each patient's recent use of pain medicine use, with requests to review the need for medicines and non-pharmacological therapies, as well as education for self-management. Targeted veterans with chronic musculoskeletal pain received an educational brochure on the benefits of a multi-modal approach to management. Change in use of pain medicines as a result of the intervention were assessed using a Wilcoxon signed rank test.

RESULTS: Tailored educational materials were mailed to 5,341 GPs and 8,440 veterans. Fifty-seven percent of doctors reported the prescriber feedback would assist them to review patients, and 82% reported they would utilise the "Six A's" of pain management when assessing patients. More targeted veterans were on lower doses of tramadol and oxycodone after the intervention. Tramadol use decreased by a median of 0.03 defined daily doses per person per day (IQR:0.00-0.22)($p < 0.0001$). Oxycodone use decreased by a median of 0.01 (IQR:0.00-0.07)($p < 0.0001$).

CONCLUSIONS: The intervention was successful in reducing the amount of opioid analgesics used by targeted veterans. The significance of this work lies in its ability to bridge the research-practice gap in the general practice setting.

Keywords: Education; quality use of medicines

Figure 1a: Targeted veterans: Average oxycodone DDD per veteran per day

Results for oxycodone: The median of the differences in post and pre DDDs was -0.01 (IQR: -0.06 to 0.02, $p < 0.0001$), suggesting a significant decrease in DDD in targeted veterans after the intervention. This indicates that more targeted veterans were dispensed lower doses of oxycodone in the post intervention period compared to the pre-intervention period (see Figure 1a). By comparison, there was no significant change in post and pre oxycodone DDDs for the historical group (see Figure 1b).

Figure 1b: Historical comparisons: Average oxycodone DDD per veteran per day

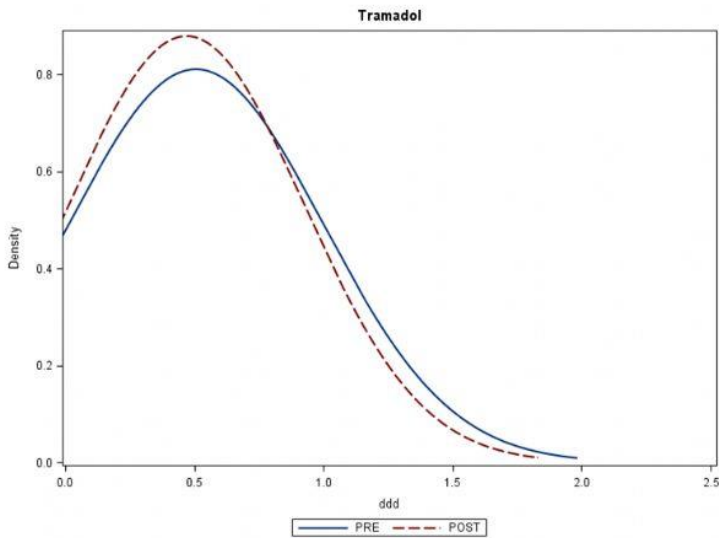

Figure 2a: Targeted veterans: Average tramadol DDD per veteran per day

Results for tramadol: The median of the differences in post and pre DDDs was -0.03 (IQR: -0.17 to 0.01, $p < 0.0001$), suggesting a significant decrease in DDD in targeted veterans after the intervention. This indicates that more targeted veterans were dispensed lower doses of tramadol in the post intervention period compared to the pre-intervention period (see Figure 2a). By comparison, there was no significant change in post and pre tramadol DDDs for the historical comparison group (see Figure 2b).

Developing a Forum for Young General Practitioners (FYAM): Helping other Countries learn by the Danish Experience

Ulrik Bak Kirk, Mads Dannesbo, Christina Svanholm, Gazelle Maghsoudi, Karolina Lewandowska
Forum for Young General Practitioners (FYAM), Denmark

Background

Since 1983, under the auspices of the Danish College of General Practitioners (DSAM), Denmark has had a formal structure for Young GPs, the Forum for Young General Practitioners (FYAM).

From the very beginning, DSAM provided both administrative aid and economic efforts. A key feature in this process was that FYAM was an exact organizational reflexion of DSAM; FYAM had its own executive board. However, the engagement of members of FYAM had several characteristics shared with that of a club of pioneers or an interest group: Individual initiative was greatly celebrated and matured, but when primus motors signed out and/or graduated, the organizational knowledge, the commitment and their network vanished with them.

Methods

From 2011, when the former chairman of FYAM was elected, a new approach in engaging and attracting members was launched: Concept campaigns. The adoption of this very different approach towards professionalizing FYAM had three characteristics:

- 1) Stronger organisation. The introduction of an annual FYAM board 2 days workshop, combined with a dedicated budget to the planning and the running of a yearly campaign.
- 2) Member engagement. The members of FYAM working together as a group and use of individual resources and skills towards achieving a common goal.
- 3) Innovative communication. The campaigns of FYAM were evaluated by their impact and level of dissemination, which is why communication and use of different media was a key feature in the entire process.

Results

The concept campaigns proved effective and efficient in engaging current interest and attracting new members to the Forum for Young General Practitioners in Denmark.

The combination of gadgets and online communication contributed in a positive way to the dissemination and reach of the campaigns' messages.

Conclusions

Organizational support when developing a formal structure for Young GPs is essential.

A cross-media communication strategy proves very valuable.

Keywords: Motivation, Engagement, Campaigns, Network, Developing a Forum for Young General Practitioners(FYAM)

Use of Campaign Activity made a difference, it made GP training better - A case report from Denmark

Ulrik Bak Kirk, Mads Dannesbo, Christina Svanholm, Gazelle Maghsoudi, Karolina Lewandowska
Forum for Young General Practitioners (FYAM), Denmark

Background

In 2012, the Forum for Young General Practitioners (FYAM) in Denmark introduced the first member-oriented campaign.

The campaign was designed with the purpose to strengthen the learning outcome of GP trainees, focusing on daily based supervision.

Methods

The campaign was introduced and launched using a video presentation at the Danish College of General Practitioners' annual

meeting in 2012. The campaign slogan was "rp. Supervision, ds. 30 min. daily + pn." written on a prescription block.

- We used different platforms to secure the impact of the campaign. We used self produced silent movie clips, gadgets (coffee-cups) etc.

- We made internet based material with examples on different tools for quality improvement of supervision. Newsletters were published during the campaign year, each time including a new silent movie clip.

- We also introduced an award given to a GP supervisor, who had contributed to high quality supervision for GP trainees. The GP supervisor was honored at the Danish College of General Practitioners' annual meeting in 2013.

Results

After the campaign, the Danish College of General Practitioners (DSAM) recommended GP supervisors approx. 30 minutes of daily supervision of their GP trainees, creating precedent for increased supervision of GP trainees.

Conclusions

The campaign coffee cup was placed at every GP trainees desk in every part of Denmark that year. Even the Danish Minister of Health took a sip of the cup. This was the very first campaign introduced by FYAM.

The impact of the campaign was greater than expected. The level of supervision before the campaign was given in arbitrary doses with great variation among GP supervisors.

After the campaign, the GP trainee can now refer to the recommendations given by DSAM.

The campaign was received well from both GP trainees and GP supervisors.

Humanized Waiting Room: optimizing time and offering health knowledge to the community assisted in a Public Health Unity in Brazil

Ana Rosa Murad Szpilman, Amanda Passini Fraga Falcão, Thaís Viana Ribeiro, Luiza Costa Cysne Dos Santos
Department of Public Health, Vila Velha University, Vila Velha, Brazil

BACKGROUND & AIM

The waiting rooms in the Public Health Unities in Brazil are most part of the time inert, where patients have only one GOAL: wait to be called for their medical appointments. Based on this fact, the medical students proposed to implant the Humanized Waiting Room in a Public Health Unity where their internship takes place, converting the inertia in health knowledge for the patients.

METHODS

The idea was presented to the health unity coordinator. After approval, the group met with the doctors and discussed about the community assisted, defining topics for each week of internship. Dynamic techniques and special tools were used to make this educational activity interesting. The first themes were: Quality of Life and all its determinants; Sexually transmitted diseases. Through a slide presentation, the students “played” with patients about Myths and Truths, asked questions to stimulate participation and used group discussion and debate.

RESULTS

In the beginning, the patients presented resistance to participate, and concern of delaying their medical appointments. It was explained that the objective was to use only the waiting time to discuss some important health subjects. After overstepping the initial opposition, the participation was effective. The patients, after the appointment, joined the group again to continue participating. The doctors approved the project because the patient was more satisfied and not complaining about waiting for the appointment.

CONCLUSIONS

The health educational activities must be realized in an interactive way with the population, exposing themes of daily utilities using simple vocabulary, to instruct and offer knowledge to the patients, avoiding relating educational activities to adjectives like monotonous, inopportune, useless, and boring for most part of the population. The idea is to continue with the project choosing different topics, with the unity health professionals and the population.

The Importance of “Voices of the Street” Project in Health Promotion and Training of Humanized Professional

Luiza Breuel Luz, Daniel Rosa Amaral, Eduardo Mikio Sasaki, Carolina Alice De Camargo Valente, Bárbara Breda Stella, Ângela Eugênio Rizzato, Marco Aurélio Janaudis, Suzana Guimarães Moraes
Voices of the Street, Jundiaí Medical School, Jundiaí, Brazil

Background & AIM: The Voices of the Street Project, led by students from Jundiaí Medical School, Brazil, conducts prevention and health promotion in poor areas of the city of Jundiaí, stimulating contact with the student and population. Thus, search the formation of a humanized professional addition to strengthening the principle of least curative health and more focused on primary care. **METHOD:** The events take place in public schools, through workshops, created and performed by the students themselves, aimed at specific age groups on topics such as prevention of breast cancer and alcohol consumption, and health joint efforts in public squares that develop through circuits with the collection of data such as blood pressure, glucose, and anthropometric measures. **RESULTS:** The Project aims to put the student in contact with the population, which receives help and promote the humanization of medicine along these students. The importance of PVR is the students' opportunity regarding a relationship "student / patient" more humane since the early years of education. Allied to this, the project allows the realization of prevention and health promotion in poor communities, promoting a mutual benefit for the population and for the volunteers. The workshops allow people receive information about care and prevention, improving the quality of life of that group. Furthermore, the active principle from the student learns the importance of health promotion as well as to communicate, making it a more human professional.

Integration of Education-Service in far communities: experience of medical students from Federal University of Mato Grosso do Sul, Brazil, 2010-2014

Milca Lopes De Oliveira¹, André Vinicius Batista De Assis², Crhistinne Cavalheiro Maymone Gonçalves³

¹Faculty of Medicine, Federal University of Mato Grosso do Sul

²Department of Health Secretary of Mato Grosso do Sul and Master student of Instituto Sirio Libanes de Ensino e Pesquisa

³Faculty of Health Sciences, Medicine, Federal University of Grande Dourados

Background & AIM: There are difficulties to manage health services because there are not human resources, such as doctors to establish in far municipalities. Mato Grosso do Sul, a state in midwestern Brazil, is developing a special partnership with Faculty of Medicine – from Federal University of Mato Grosso do Sul, State Department of Health (SES-MS) and two Municipalities Department of Health. The objective is stimulate that students may create alliances and to see future possibilities to establish in similar communities.

METHOD: During 2010-2014, medical students of end year go to the communities, during five weeks, accomplish and realize of practice family's activities with municipalities's tutor in Health Units of Health Primary Care. To evaluate experience results were collected perceptions during this period from medical students and municipalities's tutor and Faculty of Medicine's tutor.

RESULTS: The experience was aimed at learning and assistance to implement actions to families. The differential of this experience was assigned from 'students' as: autonomy, knowledge of users and community, integrality, knowledge exchange, greater knowledge of Health System; 'municipalities tutor's': academic help in solving cases, leadership in educational activities, population approval, importance of teamwork and intersectoral; 'tutor Faculty's': awakening to the family health strategy, teamwork, elimination of (pre) conceptions of Health System. The perceptions signalled that is necessary create more opportunities to discuss cases and management between health team and students.

CONCLUSIONS: The partnership is important to strenghten alliances between students and communities, with prospectives results for them, as new opportunities. It is essential to boost new experiences in medical education, aimed at integrating teaching and service-community.

The importance of communication - the wand of a Family Doctor

Pedro Caetano¹, Carolina Martins Moreira², Celia Pinho³

¹USF Nova Via - CHVNG, Porto, Portugal

²CHP - Serviço de Fisiatria, Porto, Portugal

³University of Porto, Porto, Portugal

BACKGROUND:

Communication is probably the most powerful weapon that family doctors have to convince and impress the patient to do what is best for himself.

Clinical knowledge, as well as good technique are very important skills, nonetheless, communication provides the vehicle and establish the connection to provide quality patient care. Doctor-patient communication has been well researched. Less is known about the educational background of communication skills and intercultural training.

Due to migration, doctors treat patients from different ethnic backgrounds. This causes communication challenges. To develop training programs for doctors in intercultural communication (ICC), it's important to know which barriers determine the quality of ICC.

This research aimed to provide an overview of the literature in ICC and lived experience from a Family Medicine trainee in a refugee-camp.

METHODS:

Bibliography research, collected data and lived experience from the author in MaeLa Refugee-Camp Thai-Myanmar border.

RESULTS:

Due to the author be a foreigner and did not speak the native-language, plus the obstacle of Thai nurses, spoke Burmese, to Karen people, verbal-communication was an issue. It was noticed that patients perceive non-verbal communication, as facial expressions, to be more compassionate, comprehensive, caring and likely to understand better. These were associated with improved medication compliance and patient outcomes.

Non-verbal communication is an important component of the physician-patient interaction. Migrants and refugees patients face specific emotional and psychological issues requiring additional physician emotional support.

The longer the period in which the author was living there and the better the knowledge of culture and beliefs, better was the acceptance by patients.

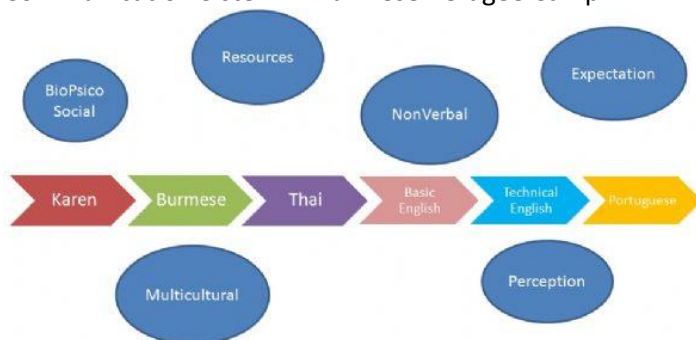

CONCLUSION:

When an educational continuum is realized and attention for doctor-patient communication and intercultural background is embedded in the working context of doctors in training, benefits will be strong.

Training for improving ICC can be developed as an extension of existing training for patient-centered communication.

Hippokrates and FM360°: European and International Exchange Programmes for General Practitioners

Rosa Avino¹, Ana Barata², Sara Rigon¹, Patrick Reichel³, Per Kallestrup⁴

¹General practice, Italy

²General practice, Portugal

³General practice, Austria

⁴Center for Global Health at Aarhus University, Aarhus, Denmark

BACKGROUND & AIM: Exchange Programmes for young and junior GPs are initiatives that have been increasing in popularity over the past years as they provide the unique opportunity for many enthusiastic young GPs to exit their comfort zone and observe different practices. The Hippokrates Exchange programme was launched 15 years ago in Europe and more recently the global Family Medicine 360° (FM360°) that, despite its young age, is being welcomed by many colleagues around the world.

The aim is to present the strengths and the opportunities of such programmes and to present the latest trending data of both, Hippokrates as well as FM360°.

METHODS: The poster will include a description of the exchange programmes and a step by step guide on how to take part into them. There will be also an overview of the activities that many European participating countries have organised nationally (conference exchanges).

RESULTS: Exchange programmes promoted by the Vasco da Gama Movement (VdGM) have grown considerably over the past years. There has been both an increase of the number of participating countries, as well as of the number of colleagues who wish to expand their horizons in the process of globalisation of Primary Care.

CONCLUSIONS: With this poster, viewers should be able to appreciate and understand the potential value of exchange programmes being motivated to participate in such an initiative. By having an overview of the practical

framework of the exchange programmes, they can understand how they may take part in them. Exchanges have shown to be beneficial for both visitors as hosts as they promote participants to get out of their comfort zone and to rethink how they may improve Primary Care provision for the population they work with.

³Torre Pacheco Health Centre

BLACKGROUNDS AND AIMS:

Based on the Resolution of the Ministry of Education, September 7, 1994 (BOE of 09/23/94), which introduces in basic education the "cross-cutting themes" including health education, and in Article 5.2 of the Law on Prevention of Occupational Risks, which include as an aid in the prevention culture: family, teachers and health professionals, we went to school to teach a short course on first aid for children in 6th grade. They answered a questionnaire to confirm the knowledge acquired, also asking for their health vocation. We aim to teach basic and useful concepts in prevention and make them feel interested as well as giving importance to our profession.

METHOD:

It is a cross-sectional study carried out on the total students in sixth grade (95). Using a questionnaire of 12 items previously validated. Statistical Analysis T-student, G-STAT 2.0 software, considered to be significant at $P < 0.05$.

RESULTS:

Women 42.48 %, 51.58 % men, they want to be a doctor when they are older 33.68 % (51.60 % women, 48.40 % men). As for first aid, 78.95 % learned the first thing to be done when dealing with an injured person, within the treatment of bleeding 85.26 % answered correctly. Correct answers regarding the syncope 63.68 %, higher number of failures in hypoglycem (50.53 %). In the Heimlich maneuver almost 90 % both in theory and practice. The 83.51 % answered adequately about burns. The overall result was enormously satisfying, as only 3.16 % had a mark less than 5, with an average rating of 8.01. Finally, we do not find statistically significant difference between the number of correct answers, preference for being a doctor and sex.

CONCLUSIONS:

- 1-. Need for health education (family and school). Concept of prevention.
- 2.-To stand out the children's ability to discover and learn

Evolution of the quality of working life for family and community medicine residents in Spain: preliminary results

Jose Maria Tenias¹, Vicente Gonzalez Roma², Ana Arbaizar¹, Marta Álvarez¹, Jesus Yeves², Ana Hernandez Baeza², Luminita Patras², Francisca Gil Latorre¹, Carmen Fernandez Casalderrey¹, Lina Canet¹

¹Teaching Unit of Family and Community Care, Valencian School for Health Studies (EVES), Valencia, Spain

²Social Psychology Department, University of Valencia, Spain

Background and Aim. To assess the evolution of a set of quality of working life (burnout) indicators and their possible causes in family and community medicine residents during their first year of residency.

Method. A cohort study with repeated measures design. The study population consisted of 63 residents who began their residencies in May, 2013, in the city of Valencia, Spain. Data were collected three times with a self-reporting questionnaire administered at six-month intervals (T1: June 2013, T2: December 2013, T3: June 2014). The response rate was 60.3%, 81%, and 38.1%, respectively. The three dimensions of burnout (emotional exhaustion, cynicism, and self-efficacy) were measured along with three of their determinants (informal support, institutional support, and pressure at work). A descriptive analysis (means and standard deviations) and comparisons between the three sets of responses are presented.

Results. The means obtained for informal support (T1=4.71±0.71, T2=4.3±1.04, T3=3.81±1.10; range of the response scale: 1-6) and institutional support (T1=4.49±1.13, T2=3.99±1.07, T3=3.16±1.18; range: 1- 6) indicate a decrease in the level of support as perceived by residents. The mean observed for pressure at work (T1=4.43±1.02, T2=4.74±0.98, T3=4.81±1.24; range: 1-6) shows an increase over time. Means for emotional exhaustion (T1=3.54±1.21, T2=4.12±1.44, T3=4.60±1.38; range: 1-7) and cynicism (T1=2.11±1.10 T2=2.25±1.04, T3=2.41±1.08; range: 1-7) increased, whereas the means for personal efficacy exhibited a U-shaped pattern (T1=5.14±1.07, T2=4.84±1.02, T3=5.33±0.85; range: 1-7).

Conclusions. The results show that the quality of working life indicators for the family medicine residents under study tended to worsen over the first year of residency.

Keywords: Quality of working life; Psychosocial environment; family and community medicine residents

Changes in knowledge of and attitudes towards Family Medicine along the degree of Spanish medical students from two different curricula

Maria Candelaria Ayuso¹, Francisco Escobar¹, Jesús López Torres¹, Julio Montoya¹, Juan Manuel Téllez², Francisco Campa³

¹Albacete Area IV Health Centre, Health Care Service of Castilla-La Mancha, C/Seminario 4, 02006 Albacete, Spain.

²Albacete Area V Health Centre, Health Care Service of Castilla-La Mancha, C/, Profesor Macedonio Jinénez s/n, 02006 Albacete, Spain

³Sevilla Faculty of Medicine, Health Care Service of Andalucía, Av. Sánchez Pizjuán, 41009 Sevilla, Spain

Background & Aim

A course in Family Medicine (FM) could dispel possible negative stereotyping about the specialty. When it is preferable, at the beginning or at the end of the degree?

To determine changes in the knowledge of and attitudes towards FM between 2nd-6th year of medical students who completed a course in primary care (PC).

Method

Cohort study. Students from two medical schools (A: course in PC in 2nd year; B: course in PC in 6th year) were asked to respond a questionnaire including the brief CAMF and socio-demographic and academic items. In A they were requested to respond before the PC course beginning, and the day of the final exam; 2nd year students from B at the end of first trimester. All of them were invited to respond at the end of their 6th year.

Statistical analysis was performed with SPSS 17.0: Chi square, Student t/non parametric tests.

Results

In A, at the 2nd and 6th year, 88 and 64 students responded, respectively; 50 and 98 at B.

In 6th year the mean age was 23 in A, 24 in B (p=0.003); 53.1% and 71.0% were women (p=0.008).

A: after completing the PC course 43.7% students said they would like to become a family doctor in the future (vs 36.5% before the PC course, p=0.028); 22% in B (p=0.01 vs A at the end of 2nd year). At the end of the degree were 35.9% and 55.1%, respectively in A and B (p=0.02).

A: the mean CAMF scores were 15.4 (SD:7.0), 22.7 (SD:7.1), 21.8 (SD:7.1) before and after the PC course and at the end of the degree. B: 13.9 (SD:6.4), significantly lower than A after PC course (p<0.0001), 23.5 (SD:5.7), no significant differences respect to A.

CONCLUSIONS: Student interest by FM showed at their 2nd year decreases at the end of the degree. Although there were no significant differences on CAMF scores, students from B showed

Last Year Medical Students' Perceptions And Attitudes About The Family Medicine- A Qualitative Study From Ondokuz Mayıs University, Samsun – Turkey

Aysenur Alper Gurz, Fusun Artiran Igde

Department of Family Medicine, Ondokuz Mayıs University, Samsun, Turkey

Background& AIM: Over the last ten years medical students have shown little interest in family practice as a career. In this study, we aimed to investigate medical students' attitudes and perceptions towards the family medicine.

METHODS: In this qualitative study we ran five focus groups involving 40 final year medical students and analyzed factors influencing participants' interest in working in general practice. A trained interviewer recorded, transcribed and subjected to content analysis from December 2011 to February 2013.

RESULTS: Forty students (female 22, male 19) participated with an age range of 22-16 years, described their opinions about the primary healthcare services, attitudes and perceptions towards general practice as a career choice.

Answers on main domains are summarized:

1. Students couldn't answer clearly to the question 'What do you think about being a family physician?'. Most of them said that the flexible working hours, lifestyle and low risk of malpractice make the family medicine attractive but lower prestige, holistic care, uncertain future of the family medicine in Turkey, long term care responsibility were negative effect.
2. Students believe that there is lack of information about the family medicine by public and by health professionals.
3. Students believe that faculty staff introduce the primary care as a punishment place.
4. Most of the students think that family medicine clerkship program change their attitude toward the primary care.

CONCLUSION: In general, although some students find family medicine attractive, it is generally considered as a career of low interest and prestige. Understanding the factors influencing medical students' choice about the family medicine is crucial. In order to increase the interest in primary care, family medicine clerkship program should take place in every medical faculty curriculum.

Health 2.0: Training intervention on health searches on the Internet

Gemma Rovira Marcelino, Beatriz Jimenez Muñoz, Gastón Ezequiel Vázquez Pirillo, Jordi Joseph Vilaplana, Helena Ferrer May, Rodrigo Gonzalo Perla San Martin

EAP Sardenya, Barcelona, Spain

INTRODUCTION:

The population attending primary care services are increasingly turning to the Internet for guidance on health.

OBJECTIVE:

Analyze and define the patient profile and searches performed by health patients through Internet before and after an educational intervention.

MATERIAL-METHODS:

Before-after intervention study with no control group. Non randomly selected participants attending workshops given by previously trained medical personal on web resources and appropriate health media for patients between May and November 2014. Each participant completed a self-administered questionnaire before the workshop and another by telephone 2-3 weeks later. The results before and after training were compared using the McNemar test for dependent samples.

RESULTS:

A total of 63 individuals were included with a mean age of 64 years, 51% were women. The main source of

information was the doctor in 63% of cases comparing with 13% of Internet. Before the workshop, 71% of attendants made Internet searches for health, rising up to 86% after (p 0.02). After the workshop increased the web searches from public institutions, medical journals and patient groups, reducing the use of private and advertising websites. Reliance on the information increased from 30% to 84% after the workshop (p <0.01) and the understanding of it from 37% to 95% (p <0.01). 72% of respondents admitted having no knowledge needed to search the Internet going this result down to 33% after training (p <0.01).

CONCLUSIONS:

Many of our patients uses Internet for making health searchers, being in some cases the main source of health information. A training intervention in health centers could improve knowledge and access to trusted health information online sources for patients.

Simulation-based Family Physicians' Education

Adem Parlak¹, Nehir Parlak²

¹Department of Family Medicine, President Guard Regiment, Ankara, Turkey

²Department of Dermatology, Etimesgut Public Hospital, Ankara, Turkey

INTRODUCTION: A major challenge for medical undergraduates is the application of theoretical knowledge to the management of acutely ill patients. Students must learn to be systematic in their approach to a problem, and develop skills appropriate to working with a clinical team. However, opportunities for students to develop these attributes are limited in undergraduate training. Simulation can help academic members to achieve these aims.

DISCUSSION: Medical education technology shapes and channels medical education policy as research advancements inform new ways to educate and evaluate doctors. Educational technology and policy coalesce with emphases on effectiveness, efficiency, and trainee and teacher morale as new models of medical teaching and testing are introduced. Simulation based education is one of the popular and effective methods of continuing medical education. In health care education, simulation has become increasingly popular in the past few decades, particularly as a method to improve experiential learning environments, and developing simulation as a health care education tool. Support for improved patient safety is one of the primary motivators behind the promotion of simulation in health care. Recently, a number of health care businesses and government bodies also expressed their interest in the support of simulation programs. As a result of this interest, simulation in health care education is growing exponentially across the globe, with health care institutions, organizations, businesses, governments, and licensing and accreditation bodies accepting simulation as a method of learning.

CONCLUSION: Experiential learning, deliberate practice and the ability to provide immediate feedback are the primary advantages of simulation-based medical education. It is an effective way to develop new skills, identify knowledge gaps, reduce medical errors, and maintain infrequently used clinical skills even among experienced clinical teams, with the overall goal of improving patient care.

P-0901

Necessity for continuing medical education in management and organization at general practice for GPs from Bulgaria-a pilot study

Sevdalina Alekova Todorova

Department of Family Medicine and Ophthalmology, Faculty of medicine, Trakia University, Stara Zagora, Bulgaria

INTRODUCTION:

Organization of primary care is subject to the needs of the patient and the delivery of health services and medical care must meet the following basic principles- accessibility; equity; continuity; quality and efficiency. For the proper and successful management of practices for primary health care is required a good knowledge of health management, marketing and planning, which is necessary to develop and maintain a general practitioner.

GOAL:

The aim of the study was to be determinate the need for family physicians to include in continuing medical education in health management and organization of primary health care, which would be to support and enhance the quality and effectiveness of their activities.

MATERIALS-METHODS:

Our team conducted an extensive survey of general practitioners in Stara Zagora Region, Bulgaria, during the period from January to May 2014. It was applied direct individual questionnaire in strict compliance with the principles of anonymity and voluntariness.

DISCUSSION and RESULTS:

A significant majority of respondents feel the need to enhance and develop their knowledge in the field of health management. The family doctors are willing to engage and participate in specialized courses in management and organization of general practice and to be informed about new, current concepts, strategies and guidelines.

CONCLUSION:

As a manager and organizer of his practice, family doctor daily deal with a range of responsibilities, urgent obligations and short-term tasks. Development of knowledge and enhancement of competence in the field of management, in the acquisition of skills in the application of modern and innovative approaches for efficient, accurate and quality functioning of ambulatory for primary health care will support a prompt resolution and overcome emerging challenges in the activities of the GP.

Hypertensive and Diabetics Patients' delivery of care: importance of patients' self-care and life habits choice

Ana Rosa Murad Szpilman, Letícia Batista Nóbrega, Matheus Maia De Souza Mello, José Lucas Carvalho, Rafael Sampaio

Department of Public Health, Vila Velha University, Vila Velha, Brazil

BACKGROUND & AIM

The Arterial Systemic Hypertension and the Diabetes Mellitus are diseases associated to increase of cardiovascular morbidity and mortality. It is important for patients the doctor's appointment, but the medication isolated is not capable of maintaining acceptable glycemic and blood pressure levels. The self-care and the adequate life habits choice are key elements to control these diseases. Objective, through home visits, evaluate the hypertensive and diabetic patients health condition, comparing the life habits and the treatment adherence, stimulating the co-responsibility and health self-care.

METHODS

The medical students with the public unity health professionals performed home visits to a hypertensive and diabetic couple. During the home visits, the medications information and the life habits, like food and exercising, were investigated. The blood pressure and the capillary glycaemia post-prandial were checked. The medical handbooks from previous home visits, group participation, and routine doctor's appointment were analyzed.

RESULTS

Based on the data collected, the woman takes her medications correctly, practices physical activities, eats balanced and preserves her physical and mental faculties. In all home visits, her blood pressure and glycaemia levels were satisfactory. On the other hand, her husband, living under the same conditions, in some home visits presented unsatisfactory levels, probably related to his lack of discipline with his medications, physical activities and eating habits, collected during interviews, by examining his medical handbook and his group participation and number of absences to his medical appointments.

CONCLUSIONS

Medications, doctor's appointment and group participation are essential for hypertensive and diabetic patients' blood pressure and glycaemia levels controlling. However, it was clear that self-care and adequate life habits choices are the only path to actually achieve treatment success, promoting a better quality of life, avoiding unnecessary hospitalizations and extending their life expectancy.

Genogram: a family therapy wider view based on graphical representation

Ana Rosa Murad Szpilman, Elaine Caliman Vergna, Amanda Ferreira De Paula, Igor Almeida Cunha, Marcela Ramos Pereira, Thompson Dias Viana, Denise Galvêas Terra

Department of Public Health, Vila Velha University, Vila Velha, Brazil

BACKGROUND & AIM

Genogram is a graphical representation of a family, showing its history and familiar pattern, identifying basic structure, functioning and the relationships established among the family members, constituting a patient familiar relational map. The aims of this study were to comprehend the affective relationships among the family members and to identify the stress factors and their influence in the health-disease process of all members.

METHOD

The family genogram was built based on the information collected on home visits and interviews with the health community agent, from august to October 2014.

RESULTS

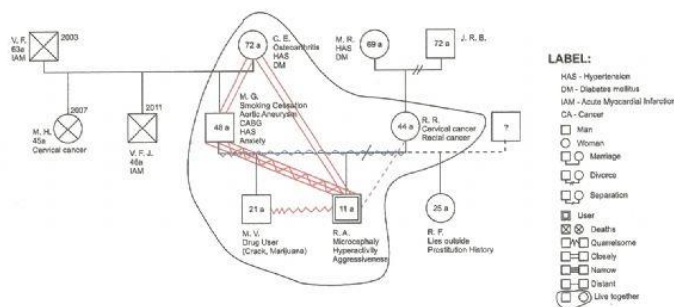

The medical students' choice to build a genogram was based on the difficulties found to define a therapeutics conduct, which would be able to embrace all the family context complexity. Based on this graphical representation, it was possible to identify the patient who needed the most health care, and on the other hand how his needs reflect on his family, generating frustration and anxiety, because his aggressiveness was not been controlled by the medicamentous therapy. In many opportunities, it was possible to observe the mother absence to his son's cares and the overloaded father who had an enormous difficulty to deal with the family's problems. Therefore, the genogram was an important tool to elaborate a therapeutic plan for the entire family, including the psychological children and parents follow-up.

CONCLUSIONS

This family genogram made possible for the medical students and the health unity professionals identify the factors interfering in the entire family health-disease process, showing possible paths to overcome the difficulties on treating this family needs, extrapolating the health needs. It was essential to include the social and relational factors, which without dealing with them, it would not be possible to achieve success on improving this family quality of life, and, therefore, their health conditions.

Organizational Identity Interpretations of a Health Higher Education Institution that Prioritizes the Primary Care

Wilton Paulo De Freitas Martins Vieira, Henrique Batista Araujo Santos, Hugo De Souza Motta Moreira, Anny Priscila Gutemberg Pinto, Pedro Thiago Hideyuki Takagi, Ubirajara José Picanço De Miranda Júnior ESCOLA SUPERIOR DE CIÊNCIAS DA SAÚDE (ESCS), BRASÍLIA-DF, BRAZIL.

BACKGROUND AND AIM: The organizational identity is the collective understanding of an institution main characteristics. The identity formation process is linked to the organizational identification, which refers to members' level of involvement inside the organization. This identification is the key to the maintenance of success, and has a strong impact on the construction of a mature and solid image. It was considered that the organizational identity of Escola Superior de Ciências da Saúde (ESCS) – an institution that uses a new methodology to graduate health professionals, prioritizing family health strategy – is inconsistent and not well defined across its members. Consequently, this work aims to analyze members' organizational interpretations of their institution. **METHOD:** It was an analytic, descriptive, transversal, quali-quantitative study, which used data collected from two focal groups and the application of a Likert scale test. All the research subjects were professors and students from the first and last years of the medical and nursery courses, management and administrative boards from ESCS. **RESULTS:** The study indicates that members of the institution confuse the health school with the Health State Office, and think that all courses have similar challenges. The nursery school does not agree that the separation of the health school in two different campuses has an impact on identification. Among all professors and students in the study, only the 6th year medical students agree that the methodology adopted was effectively incorporated. In addition, the fact that ESCS is a young and not well-known institution contributes to the generation of a yet fragile image. **CONCLUSIONS:** Different interpretations of organizational identity were found. The work demonstrates the lack of identification as a result of the low understanding and incongruence of the organizational identity. The development of new studies and strategies are necessary to increase the identification level in the institution.

Do we know the inhalation technique in Primary Care?

Maria Ortega, Nuria Sánchez, Laia Gené, Cristina Blaquez, Nora Selvi, Amparo Hervás Consorci d'Atenció Primària de Salut de Barcelona Esquerra, Barcelona, Spain

AIM:

To describe the degree of knowledge of health professionals in Primary Care (PC) about inhalation technique with different devices and more common mistakes

METHODS:

Descriptive study in an urban Primary Care Center, with 32 professional staff, 19 physicians (59.4%), 13 nurses (40.6%). In individual survey, professionals were requested to explain in detail the inhalation technique with 10 different inhalers. The steps to take in the inhalation technique were recorded, considering mistake the omission of indications (according to the SEMFYC's guide of health education in asthma). Variables: Age, sex, professional category, degree of knowledge measured in percentage of correct answers.

RESULTS:

Median age: 42.6 ± 10.9 SD, 87.5%female. Health professionals showed a higher level of knowledge in the use of spacer Chamber (46.35%), Pressurised metered-dose Inhaler (pMDI) (38.75%), Handihaler (36.95%), Turbuhaler (34.38%) and Accuhaler (31.01%). Lower level of knowledge were presented in the use of the following inhalers: Breezehaler (13.6%), Genuair (11.38%), Nexthaler (5.29%) Respimat (8.41) y Easyhaler (5.15%), noting that the last two devices, no nurse referred to know them. In >95% of the surveys, most common mistakes were not to indicate: to bend the head back, not to interpose the tongue, not to blow by the mouthpiece and information for maintaining the device.

CONCLUSIONS:

The degree of knowledge about inhalation technique showed by health professionals, physicians and nurses, in our Primary care Center is low generally, according to others studies. We consider convenient to realized theoretical and practical workshops to update inhalation technique knowledge in both groups

Use of Electronic Health Record (EHR) in the consultation: the impact of a training intervention on physician-patient interactions

Cédric Lanier¹, Melissa Dominicé Dao¹, Patricia Hudelson¹, Bernard Cerutti², Noëlle Junod Perron¹

¹Division of primary care, Geneva University Hospitals, Geneva, Switzerland

²Geneva Faculty of Medicine, Geneva, Switzerland

INTRODUCTION:

Electronic health records (EHR) are now widely used in outpatient medical settings. Although the first minutes of the consultation are considered essential to establish a good physician-patient relationship, little is known about how doctors use EHR while initiating the consultation. The aim of the study was first to evaluate EHR use in terms of physician-patient interaction and second to assess the impact of training on how to use computer/EHR during clinical encounters during the first 10 minutes of the consultation.

METHODS:

A pre-post study was conducted at the Division of primary care of the Geneva University Hospitals. 24 residents were invited to take part in a 3-month training program focusing on how to use computer/EHR during clinical encounters. The intervention included two group training sessions and 2-4 individual supervisions based on residents' own videotaped encounters. Residents were asked to videotape 3-4 encounters before and after the intervention. Outcomes measures were objective analysis of computer use in relationship with the content of the interaction (using the Roter interaction analysis system).

RESULTS:

17 residents took part in the study. Pre-intervention, the first 10 minutes of the physician-patient interaction included the following contents: 29% emotional, 17% medical, 11% therapeutic and 6.6% psychosocial. The time spent using EHR during each type of discourse was: 29.8% medical, 26.6% therapeutic, 24.5% psychosocial and 21.1% emotional. Post-intervention, the overall proportion of time using EHRs decreased significantly (53.2 vs 49.8% $p < 0.0001$) and more specifically during psychosocial discourse (24.5% vs 9.76% $p < 0.0001$).

CONCLUSION:

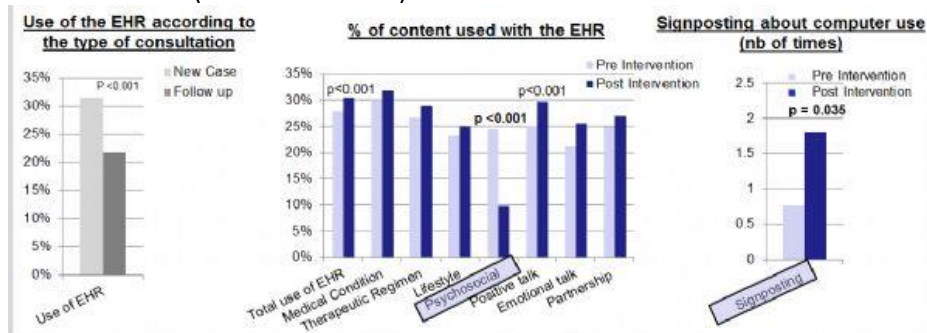

Residents use the EHR 30% of the time during the first 10 minutes of consultation. The intervention had a positive impact on physician-patient relationship since it reduced residents' use of EHR during sensitive issues such as psychosocial discourse.

Comparing the Patient-Centered Approach Levels of the Family Physicians, Psychiatrists and Residents

Sukriye Bayrak Ozdin, Fusun Artiran Igde

Department of Family Medicine, Ondokuz Mayıs University, Samsun, Turkey

Background&AIM: Biopsychosocial model is an integrated approach that includes the assessment of the interactions among an individual’s life story, living conditions and state of health within the biological-psychological and social conditions. Biopsychosocial model reflects to the clinical practice by means of patient-centered clinical method. The importance of patient-centered medical advisory reveals especially in primary care and psychiatry. In this study, it is aimed to assess the patient-centered approach levels of the family physicians, psychiatrists and psychiatry residents.

MATERIALS-METHODS: This descriptive, cross-sectional type study carried out multicenter between March-November 2014, was conducted across the country in the form of electronically attendance by means of the e-mails and in the form of manual application. Patient Practitioner Orientation Scale and a survey involving questions to determine sociodemographic characteristics were carried out to the 405 physicians, including 222 family practitioners and 183 psychiatrists/psychiatry residents. Data was assessed with the SPSS 21.0 package software, statistical significance was considered as $p < 0.05$.

RESULTS: 222 of the participants are family physicians (54,8%) and 183 of them are psychiatrists and residents (45,2%). Participated in the study, 245 physicians are women (60,5%) and 158 physicians are men (39%). The average of family physicians’ total PPOS scores is calculated as $2,93 \pm 0,41$; and the same average is $3,31 \pm 0,39$ for the psychiatrists. The averages of PPOS scores are considered too low for both areas of expertise. The patient-centered approaches of the family physicians are significantly lower than those of the psychiatrists ($p: 0,00$).

CONCLUSION: In this study it is concluded that physicians do not practice the patient-centered clinical method sufficiently, especially the biopsychosocial approaches of primary care physicians’ are more inadequate. Raising the consciousness of physicians and focusing on this issue in education would be effective in the physicians’ perspectives and their clinical practices.

Objective exchange experience: Provide an opportunity for residents and young physicians family medicine in various European countries, to exchange ideas and projects in order to improve skills in primary care. The frequent aim it is to observe differences of health systems, but also important to learn communication skills in primary care.

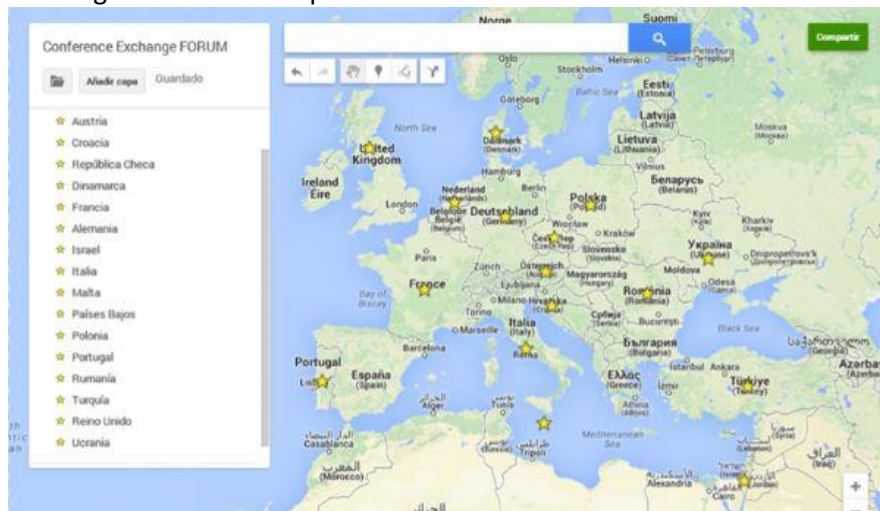

Description: occurs in the organization of the first forum of Vasco Da Gama movement in 2014, an exchange experience for physicians from various countries in Europe during two days before. Committee was formed to establish a program. Several teaching units were contacted to receive GP trainees and young GP to participate. Tutors with basic english or other foreigner language were interested in hosting in their clinics. Two days they saw how was a center and its patients. They participated centers in both urban and rural primary care, emergency care centers and primary care research units. But committee had understood the situation of our GP visitors, so for help decided to write a dictionary (spanish-catalan-english) of the main important words to continue a conversation in appointment and also technical words. Nevertheless, without leaving the importance of no verbal language needed when you don't understand the language.

RESULTS: More than 30 young doctors from 16 European countries participated. They collaborate in translating the important words to their own language so all would share and increase our knowlegde. We received the translations in italy, french, turkish, german, polish, dutch, portuguese, czech.

CONCLUSIONS: Applicability With such exchanges can achieve cultural exchange and open mind family medicine, learn essential skills in the consultation. We can learn from experiences of other colleagues, but our more precious tool in Primary care is the communication, verbal and non verbal. Many more experiences we needed to measure the impact on training and practice of primary care physicians.

Comparing the Empathy Levels of the Family Physicians, Psychiatrists and Residents

Sukriye Bayrak Ozdin, Fusun Artiran Igde

Department of Family Medicine, Ondokuz Mayıs University, Samsun, Turkey

Background&AIM: The importance of patient-centered medical advisory and empathy reveals especially in the primary care and psychiatry. In this study, it is aimed to assess the empathy levels of the family physicians, psychiatrists and psychiatry residents.

MATERIALS-METHODS: This descriptive, cross-sectional study carried out multicenter between March-November 2014, was conducted across the country in the form of electronically attendance by means of the e-mails and in the form of manual application. The Jefferson Scale of Physician Empathy and a survey involving questions to demonstrate sociodemographic characteristics were carried out to the 405 physicians, including 222 family practitioners and 183 psychiatrists/psychiatry residents. Data was assessed with the SPSS 21.0 package software and statistical significance was considered as $p < 0.05$.

RESULTS: 222 of the participants are family physicians (54,8%) and 183 of them are psychiatrists and psychiatry residents (45,2%). The majority of the participants were between 24-35 years old physician (n:289, %71,4), and the average age was calculated as 33,84 (SD: 8,63). The average of family physicians' total JSPE scores is calculated as $78,79 \pm 11,45$, and the same average is $81,78 \pm 8,33$ for the psychiatrists. The average of psychiatrists' total empathy scores is found significantly higher than that of family physicians ($p: 0,003$).

CONCLUSION: It is concluded that especially the primary care physicians' empathy level is more inadequate and physicians generally do not adopt the patient-centered clinical methods. It can be thought that this situation is related to the imperfect knowledge of physicians, their inability to allow enough time for their patients due to the busy schedules and their lack of motivation due to the changing health policies. Thus, it would be guiding for physicians to raise the consciousness of them, discuss the subject efficiently in medical education and in-service training and to make more researches and studies.

Arterial Hypertension treatment adherence: essential for blood pressure control

Ana Rosa Murad Szpilman, Adilson Segades Leite, Moysés Ost Damm Martins, Bruno Fianco, Luiz Felipe Cunha Nascimento, Gustavo Oliveira Pacheco

Department of Public Health, Vila Velha University, Vila Velha, Brazil

BACKGROUND & AIM

The Systemic Arterial Hypertension is one of the most prevalent diseases in the world, demanding special attention from the public health systems, dedication from the health professionals, and specific approach in the medical graduation process. In Brazil, the hypertension prevalence in adult population ranges between 15 to 20%. It is well known that effective treatment can control blood pressure and reduce its impacts in the population health, also decreasing the health systems costs. This study aimed to evaluate the relation between treatment adherence and hypertension control.

METHODS

The Vila Velha University Medical Students with the Public Health Unity team analyzed the hypertensive medical handbooks, their group participation, the data collected through home visits and their attendance to doctor's appointment. The data was collected from March 2013 to March 2015. The raised information were based on the World Health Organization parameters, such as blood pressure, abdominal circumference and the Body Mass Index.

RESULTS

The Public Health System in Brazil organizes the Primary Health Care through Family Health Strategy, which works with territorial basis; interdisciplinary attention with a health professionals' team. The area that this group of students performs their internship has four Community Health Agents who take care of four micro areas. The total amount of Hypertensive patients registered in this area were 637. After data analyzes, 89% of the patients presented improvement in their blood pressure control, showing that the hypertensive groups, the doctor's appointment and the home visits are achieving their GOAL: improve life quality for those who suffer from a chronic disease that can be controlled, by stimulating the patient treatment adherence.

CONCLUSIONS

Treatment Adherence incentive programs can contribute to better blood pressure control, granting better quality of life and life expectancy, besides possible decreasing in avoidable hospitalizations and complications consequence of this condition.

Actualization of continuing medical education of general practitioners concerning hereditary pathology

Sevdalina Alekova Todorova¹, Borislav Nikolov Popov², Veselina Petrova Tacheva³

¹Department of Family Medicine and Ophthalmology, Faculty of Medicine, Trakia university, Stara Zagora, Bulgaria

²Department of Molecular Biology, Immunology and Medical Genetics, Faculty of Medicine, Trakia University, Stara Zagora, Bulgaria

³Department of Molecular Biology, Immunology and Medical Genetics, Faculty of Medicine, Trakia University, Stara Zagora, Bulgaria

INTRODUCTION:

In his practice the GPs is often faced with patients with hereditary diseases and predispositions / patients with monogenic diseases, congenital anomalies, socially important multifactorial diseases, etc./. There of is often required to speak competently and clearly reasoned opinion for the genetic analysis, optionally interpret obtained results, provide an accessible way for the patient information on a hereditary disease and to point him to the appropriate specialist.

GOALS:

1. To examine the knowledge of GPs on clinical manifestations and existing opportunities in Bulgaria for early diagnosis, prevention and treatment of their patients with hereditary pathologies.
2. To investigate the motivation and engagement of GPs in organized thematic courses, informing them about innovations in the field of medical genetics and genetic research.

MATERIALS-METHODS:

It was conducted extensive sociological survey among general practitioners in Stara Zagora region for the period December 2013 - March 2014.

DISCUSSION and RESULTS:

74% of respondents indicate that they have in their practice for primary care patients with hereditary pathology. 91% of respondents have studied the discipline "Medical Genetics" during their training for the acquisition of higher medical education.

However, vast majority of GPs consider that they are not enough familiar with the clinical picture of genetic diseases / 79 %/, with contemporary methods for diagnosis of genetic diseases / 93 %/ and with the main approaches to treatment and prevention of hereditary pathology / 88%/. 97% of family doctors need additional information about opportunities in the country for the early diagnosis of hereditary pathology, current approaches to follow-up and treatment.

CONCLUSION:

GP has a key role in the prevention of hereditary pathology. To achieve this goal structured and thematic continuing training courses are necessary, which will inform GP of the current aspects and developments in the field of genetics

Tuberculosis data analyzes: an accurate portrayal of Vila Velha Municipality tuberculosis reality, in Brazil

Ana Rosa Murad Szpilman, Ludimilia Henrique De Souza, Erivelto Pires Martins

Department of Public Health, Vila Velha University, Vila Velha, Brazil

BACKGROUND & AIM

In Brazil, tuberculosis is a priority among the promoted Health Ministry politics, establishing the Tuberculosis Controlling National Plan, in all Brazilian municipalities. This study emerged from the medical students observations during their internship in a public health unity in Vila Velha, Brazil. The students with the unity professionals aimed to be familiar with the accurate portrayal of Vila Velha Municipality tuberculosis reality, in order to comprehend the assisted territory and community, improving the delivery of health care quality.

METHODS

The first step was tuberculosis data analyzes, in the diagnosed patients' medical handbooks in the public health unity where the internship takes place, and in the Disease Notification System. Afterwards, in order to complement the data, the students interviewed the responsible for Vila Velha Tuberculosis Controlling Program. After verifying the municipality data, the students started new cases diagnosed observation and notification in the public health unity, during their internship, trying to conquer accurate unity data analyzes.

RESULTS

Based on the interview, in 2014, in Vila Velha municipality, there were 145 new cases of tuberculosis notified, 3 deaths, 7 cases of withdrawal treatment and 21 cases of cure. It was difficult to raise the unity data, due to some reasons acknowledge by the research, such as lack of professionals' team mobilization and participation; lack of professionals' autonomy in the patient evolution follow-up, decreasing their role and involvement; lack of medical handbooks' correct filling up; lack of data basis correct feeding; difficulty to ensure patients return, because of work absence and lack of accurate information given by the professionals; lastly, there was not a government incentive to correct data registering.

CONCLUSIONS

Accurate tuberculosis data analyzes provide the professionals the possibility to recognize the assisted community reality, organizing the work process and improving the delivery of health care quality.

Keywords: Epidemiology, Tuberculosis, Public Health, Delivery of Health Care.

Systemic Arterial Hypertension: is it possible to be hypertensive and have a quality of life?

Ana Rosa Murad Szpilman, Antônio Freitas Netto, Diogo Pena Dos Anjos, Manoella Garcia Carrera, Gustavo Oliveira Pacheco, Hele Nice Faria Santos Alves Haddad

Department of Public Health, Vila Velha University, Vila Velha, Brazil

BACKGROUND & AIM

The Vila Velha University Medical students, with the public health unity professionals, promote preventive actions and health promotion activities to the assisted population. The major focus is in hypertensive delivery of health care, due to its prevalence. The Systemic Arterial Hypertension risk and aggravating factors can be divided into changeable and unchangeable. The changeable factors include social habits, such as feeding, physical activities, medication use frequency, alcoholic beverage ingestion, narcotic and toxic substances use and socio-economic factors. The aim of this study is to analyze the aggravating factors interference on hypertensive quality of life, assisted in a public health unity inserted in Brazilian Primary Health Care.

METHODS

The medical students, in a public health unity, collected data from hypertensive group meetings, home visits, interviews with the unity professionals about the hypertensive habits and clinical history, medical handbooks evaluation, doctor's appointment follow-up, formulary used to questioning the hypertensive about their habits, besides the clinical examinations results, the blood pressures measurements, the weight and high measurements and body mass index, and the abdominal circumference.

RESULTS

This student group has been attending the internship in the same unity and community for one year and a half. They created a bond with the hypertensive patients assisted and participate in all their activities, described above in the methodology. The patients who attend the meetings and the doctor's appointment, who control their feeding habits, who practice some physical activity, do not drink or use narcotic substances, take their medication regularly, and control their body weight, are more likely to control their blood pressure.

CONCLUSIONS

The hypertensive patient can modify the changeable factors, being the most effective path for improving the hypertensive quality of life. The health professionals are not able to succeed by themselves. It is essential to increase their autonomy and co-responsibility.

TEEN SAFE SEX project. The general practitioner meets students of high schools

Massimiliano Lucarelli¹, Tecla Mastronuzzi², Angela Stufano¹, Ivo Vulpi²

¹Interdisciplinary Scientific Association of both Family and Community Medicine - ASSIMEFAC

²ASL Bari, Italy

Background

Sexually transmitted diseases (STD) are infective diseases spreading all over the world which weigh heavily on public health and health care cost. The more effective intervention with the best costs/benefits ratio is prevention.

Aim

- to inform students of high schools about risks related to STDs, about prevention and early diagnosis by general practitioners (GPs).
- to improve relationship based on trust between GPs and teenagers.

Design

The project was carried out with the patronage of the city administration council and the general medical council of Bari. In 2013 and 2014 GPs gave presentations about STDs to classes of students. 2342 students took part in interactive lessons that included a pre-meeting questionnaire to assess the pre-existing knowledge, a power point presentation, a discussion, a post-meeting questionnaire to assess the acquired knowledge. At the end of the meeting students also filled in a satisfaction questionnaire.

Results

The number of right answers in the post-meeting questionnaire increased significantly, compared with the results of the pre-meeting questionnaire.

Students showed high level of satisfaction concerning the educational project.

Conclusion

Increasing awareness on STDs can be an important contribution to prevent them among teenagers. The relationship between GPs and teenagers can be enhanced by an educational initiative.

Keywords: "sexually transmitted diseases" "teenagers" "prevention" "school health" "general practitioners" "general practice physicians"

Comparison of the answers to the pre and post-meeting questions (expressed in percentage)

The pie charts illustrate the results about the question: "Can contraceptive pill reduce the risk to contract sexually transmitted diseases?". The right answers (in green) increased significantly after the meeting.

P-0915

Teaching Ethics and Law for Freshmen Medical Students: lesson learnt from a brand new school in eastern Indonesia

Harry Allan Papendang¹, Trevino Aristarkus Pakasi²

¹Faculty of Medicine Universitas Papua

²Division of Family Medicine, Department of Community Medicine, Faculty of medicine Universitas Indonesia Background. Law and ethics are important in medical practice, and every doctor needs to know the issue locally and globally. It is therefore, since the first year, students were taught school. In the Universitas Papua, the teaching was done in semester 2, and this study was aimed to describe the result.

Method. The second semester students were given the ethics and law for two weeks in a block module. The teaching method was adult learning, student centered and achieving competencies as written in the curriculum. The evaluation was cross sectional, students filled questionnaire related with the topics, teachers, method using Likert scale; and was crosschecked with the result of the written assessment and discussion in the small group. There was also a questionnaire that they could write complain and suggestion.

Results. Overall, students were enthusiastic in this module as most of them agreed and strongly agreed for the topics and learnt much in the module. Most of them passed the written exam (88%), with some notes. i.e. the question related with malpractice was not properly answered as more than 90% were not correct. In the discussion, students had little ideas about the situation in the practice that made them difficult to understand malpractice. There was also problem for students to determine prima facie. This was the ethical topics were debatable and students had no exposure to clinical situations prior to the module.

Conclusion. Teaching ethics and law were important for students, as early as possible. However it is worth to note that, early exposure to clinical situation was important to understand many of the ethical issues. It is recommended that ethics and law should be repeated and inserted in the discussions during studying other modules.

Effectiveness in training on patient-centred care in general practice

Radost Spiridonova Asenova, Levena Kireva, Zornitsa Ambareva, Daniela Mileva, Maria Semerdjieva, Gergana Foreva

Dept of General Practice, Medical University Plovdiv

BACKGROUND:

Person-centred care (PCC) is an area of competence for general practitioners relating to the context of patient as a person, about how they understand the patient and their ability to work in partnership with patients. Its implementation in Bulgarian primary care is relatively new and there are few researches in the field.

Research question:

To study the basic knowledge of GPs about patient-centred care and to assess the effectiveness of training on the topic.

METHODOLOGY:

Training, divided in three modules, has been performed with 54 GPs - 20 males (37.0%) and 34 females (63.0%). The duration of modules was 1.30h each, led by two moderators. A pre- and post-test among the GPs has been done, using an original questionnaire.

The results have been processed by SPSS 17.0 version, using descriptive statistics and nonparametric test (Chi-square).

RESULTS:

The questionnaire studies the GPs' perspectives and understanding about patient-centred care in general practice.

We found that the most unclear for GPs is how to implement so broadly defined area in their daily practice. Only 37.0% of GPs have been agreed with the importance of health care that meet patients' needs and preferences and 35,2% have pointed out the aspect - continuity of care. The positive aspect is the fact that GPs have accepted PCC as their main competence. There was a significant difference comparing the results from the pre- and post test, $P < 0.001$.

CONCLUSIONS:

The recognition and the practice implementation of the patient-centred care approach is of a great importance and requires further education of GPs in Bulgaria, it is related to the relatively new health care system organization in order to strengthen GPs' position.

The research is supported by the intra-university grand № HO - 15/2014 Poly-pharmacy and multimorbidity among geriatric patients in general practice – implementation of patient-centred approach.

Keywords: general practice, patient-centred care, education

Patient-centered care domains

Domains	Test %	Re-test %	P; χ^2 ; r
Adoption of a person-centred approach in dealing with patients and their problems, in the context of their circumstances	44,4	79,6	$P < 0,001$ ($\chi^2=14,19$) $r=0,36$
Use the general practice consultation to bring about an effective doctor–patient relationship, with respect for patient's autonomy	63,0	92,6	$P < 0,001$ ($\chi^2=14,19$) $r=0,36$
Communicate, set priorities and act in partnership	68,5	94,4	$P < 0,001$ ($\chi^2=12,03$) $r=0,33$
Provide long-term continuity of care as determined by the needs of patient, referring to continuing and co-ordinated care management	35,2	74,1	$P < 0,001$ ($\chi^2=16,48$) $r=0,39$

P-0917**Effectiveness of health education in waiting room of pensioners bank in improving elderly health perspective, behavior and morbidity**

Aria Kekalih¹, Fithriyyah Shalihati², Idqan Fahmi²

¹Community Medicine Department, Faculty of Medicine Universitas Indonesia, Jakarta-Indonesia

²Graduate Program of Management and Business – Bogor Agricultural University (IPB), Bogor-Indonesia

INTRODUCTION:

Elderly has high risk for typical age-related diseases like degenerative disease, syndrome metabolic and also infectious disease. Elderly need intensive exposure of health education to recognize and prevent the diseases. Pension bank is a place where elderly has chance to gather and spend significant time waiting to withdraw pension money every first week of the month. This condition initiated bank cooperated with trained primary physician to perform specific health education program to elderly in the waiting room. This study investigates how health education and consultation program in pension bank would be effective to change elderly health perspective, behavior and morbidity.

METHOD:

We investigated 436 elderly in 14 cities of bank branches in Indonesia and divided them in two groups: those who participated (n=342) and never had health education in waiting room (n=94) to compare their health perspective, behavior and morbidity.

RESULT:

Participated group had significant increase of health perspectives, especially about importance of regular health checking and maintaining healthy diet (p<0.05). They also had fewer case of chronic illnesses (p=0.01, OR 0.51 CI95% 0.30-0.89). Their active lifestyle was also increase but not significant (p=0.164)

DISCUSSION:

Health education in the waiting room of pension bank was proven effective to improve health perspective and decrease long term illnesses in elderly. With standardized education module and cooperation with trained health educator, this approach of optimizing queuing time in waiting room of pension bank can be applied to intensify access to health education for elderly.

P-0918**Community Health Agent -subject of action in the work completion of the Foundation Degree - their role in health team**

Renata Pekelman¹, Marielly De Moraes²

¹Health Technological Education and Research Center/ GHC School-Hospitar Conceição's Group, Porto Alegre, Brazil

²Education Department, Rio Grande do Sul University, Porto Alegre, Brazil

INTRODUCTION: Community Health Agent (CHA) is the professional in primary care that has held its training at work. 10 years ago it was decided on their training, a Technical Degree (1200 hours), yet not mandatory. This study is an analysis of the conclusion's papers, whose theme was the Community Health Agent as the subject of his action and identify how the ACS describes and defines his work through their writing; the paper was a condition to get their technical degree in CHA / GHC School / RS-Brazil. **METHODOLOGY:** It is a qualitative research, document database. Data analysis was made through content analysis method with four empirical categories: work and identity; mobilization and achievement; teamwork and the ACS's clinics. **RESULTS:** work and identity shows the territory as a contradictory space for the ACS because he should take on more of a role while he is team and community, the experience of the territory also provides an opportunity an enlarged understanding of health, building a vision completeness for health interventions; in category mobilization and achievement, identifies an individual and collective self constitution process, the record of the history reveals itself a sense of empowerment, recognition of courage for social fightings, the sense of leadership; teamwork appears as the essence of the ACS work himself, although point to a nuclear knowledge to be shared with the

team. Alterity as the essence for the development of staff; the ACS clinics, practices both in homes and in other areas of the territory can be consider a clinical practice: health care, a watchful eye to the risks and vulnerabilities, an intimate clinic with secrets, listening and welcomig. CONCLUSION: The great potential of CTACS is in power conceptualize the empirical knowledge, learn and master the technical language, create opportunities for reflection on the work.

Problem-based learning as a way to improve the postgraduate education of general practitioners in diabetes management

Victoria I Tkachenko

Shupyk National Medical Academy of Postgraduate Education

Background. Problem-based learning proved positive results at undergraduate education and only a few works (Paul B Smdits, 2003) showed its application at postgraduate education. Department of Family Medicine and Diabetology Department at NMAPE developed together 2-week postgraduate course in type 2 diabetes management at primary care with using methods of distance-learning and problem-based learning.

The aim is to analyze results of implementation of postgraduate course with distance-learning and problem-based learning during continuing professional development of general practitioners (GPs) in diabetes management.

Materials and methods. We conducted a survey of 10 GPs after postgraduate course in diabetes management to assess the implementation of the new methodology. Statistical analysis was performed using Exsell 2007, SPSS.

Results. Problem-based learning was estimated by GPs as more interesting course, than traditional one. GPs showed greater interest, noticed an unusual approach in studying material and better assimilation because of standardized simulation cases. Long-term effects at 1 year after study showed better involvement of GPs to diabetes management, better results of implementation of diabetes management guideline in general practice and preserve knowledge for a long time, that demonstrated the effectiveness and novelty of this method in Ukraine. In addition, the basic principles of patients' education according to a structured training program, recommended by WHO and IDF, and new method of using 4 interactive gaming maps, developed by IDF (2008), were presented to GPs, that allow better motivate patients to self-management of diabetes.

Conclusion. The developed 2-week postgraduate course in type 2 diabetes management at primary care improves the quality of diabetes primary care and can be use widely as part of continuing professional development. The use of problem-based learning proved the higher interest of GPs and better assimilation of the material during postgraduate education, as well as improvement of the quality of diabetes primary care in general.

FAMILY DOCTORS ACROSS EUROPE (FDAE):enhancement in education and long life learning for Italian GPs with EU funding

Laura Viotto, Claudia Felici, Ernesto Mola, Massimiliano Lucarelli

Interdisciplinary Scientific Association of both Family and Community Medicine - ASSIMEFAC,Italy
Background

The post-graduate education in general practice in Italy is not a University specialization but a triennial vocational training referred to the 21 Italian Regions. This fact has excluded the Italian trainees and trainers from european exchange, like Erasmus, and the Italian school from european research.

Aim

FDAE wants to fund european exchange among trainees of the vocational training in general practice of Italy in Finland and Spain.

FDAE wants to promote exchange also among trainers of the three countries to foster european cooperation in education and research.

Methods

The project last two years. Subjects involved in the project are: trainees and trainers of the Italian vocational training in general practice and the board of the Italian scientific association ASSIMEFAC.

Three areas have been indicated in the exchange project:

a) Area of continuing education in partnership with Galicia – Spain - and Finland: trainees will be involved in the job training concerning organization and management of primary care structures while trainers will be involved in the job shadowing

b) Area of internationalization in partnership with EU Commission - Bruxelles: trainees and trainers will be trained in development and management of project funding by European Union

c) Linguistic area in partnership with English schools of Malta: reserved only to trainers, it consists in language courses of medical English.

Budget requested: 60.000 €

Results

This project has been submitted in March 4th,2015,and we are waiting for the outcome

Conclusion

Expected results are enhancing educational levels for young and professionals GP fostering free circulation of family doctors in Europe encouraging cooperation in education and research in general practice.

Keywords: Eu funding,trainee&trainer GP exchange program,GP education

Métis project – Education for Health

Paulo Santos, Carlos Martins, Luísa Sá, Luciana Couto, Alberto Pinto Hespanhol

General & Family Medicine Unit - Department of Social Sciences and Health, Faculty of Medicine of University of Oporto, Portugal

BACKGROUND: Patient’s literacy is a key to achieve best health outcomes. The quality of information available in web based supports isn’t always very high.

AIM: To provide a tool that can improve the information available to the public

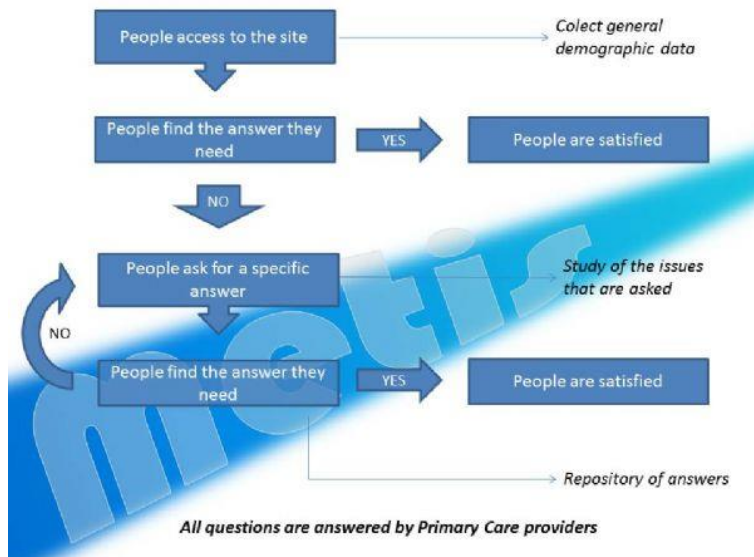

METHODS: Metis project is a web based support that offers an archive of information about health education, covering the main topics in this area, using a wiki like structure. It also allows the participant put his own question to be answered by a primary care professional, thus increasing his knowledge. These answers are added to the archive allowing others with identical doubt to benefit from it. From the academic point of view, we intend to characterize the profile of the users of this service.

RESULTS: Metis project is in the implementation phase. At this point we have about 300 texts ever built and we wait for the formal authorization of the National Authorities to open the access to the general public. The main topics are the primordial prevention, cardiovascular prevention, respiratory diseases, sexual transmission infections, stress and mental disorders, accidents, and elderly health.

CONCLUSIONS: Information is the basis for the empowerment of people. In Metis project we intend to improve literacy by providing scientifically validated information, in a clear and accessible language, that enables the citizen to make their own choices, thus improving their level of health.

Sexual knowledge and behavior of young people in Poland

Paulina Pachniak, Maria Malarska, Michał Matyjaszczyk, Przemysław Kardas, Michał Podgórski
Medical University of Lodz

There are a lot of differences between young people's sexual behaviors. They act differently in group, home or even at school. The level of their basic knowledge about sex, contraception and sexually transmitted diseases are often very low.

We wanted to check what they actually know and what are they most common behaviors. We have prepared a survey that contained simple questions which they could answer without thinking. They were about their relationships, sex life, contraception, HPV or even how they feel about their lives.

Our aim was to get most reliable answers as we can. We have placed our questionnaire in the Internet, but we have also asked personally students of middle and high schools to fill it. We received more than two thousand replays.

The number of responses gave us a full view to the situation. For example the most common contraception among young people is a condom. Other methods like pills, IUD and others make up a small percentage. The research revealed that they did not do the self-examination, they did not know how to do it and what is more they did not know that it can help them to avoid the cancer. Most shocking answer was that only few percent of girls had been vaccinated to HPV. Comparing to other European countries it is so alarming.

Due to our research results we are deeply convinced that there is a need for change here, particularly in the education program.

P-0923

Devising a curriculum for young UK military doctors

Rich Withnall

Defence Professor of General Practice, Royal Centre for Defence Medicine, ICT Centre, Birmingham Research Park, Vincent Drive, Edgbaston, Birmingham, B15 2SQ, UK

Background & Aim

The work of young doctors in the UK military differs from that of civilian doctors within the UK's National Health Service. Young UK military doctors spend up to three years at the start of their careers as General Duties Medical Officers (GDMOs). During this time, they develop military competencies whilst working in family medicine before starting their higher vocational training. These young doctors are clinically supervised, but GDMO time is not recognised as higher medical training by the UK's General Medical Council (GMC). Nevertheless, GDMOs deliver important family medicine services to patients within the UK and overseas. Until now, there has been no curriculum for young UK military doctors.

Method

A GDMO syllabus has been devised to standardise the learning objectives for all young doctors in the Royal Navy, Army and Royal Air Force working within family medicine. A bespoke GDMO Supervisors course and a new Introduction to Medical Education Course have been developed for the Associate Trainers who support the GDMOs. An electronic Portfolio has been created for recording the young doctors' developmental activities to enable an assessment of their progress against agreed educational objectives.

Results

The GDMO curriculum has linked a syllabus with new training and assessment tools. It defines young doctors' educational processes and intended outcomes whilst they work in family medicine, and enables consistent academic support from their Associate Trainers. This enhances organisational governance and assurance of the young doctors' clinical outputs, supporting high quality patient care.

Conclusions

A GDMO curriculum has been devised for young doctors working in family medicine in the UK military before they start higher vocational training. It advances clinical supervision, standardises educational activities and provides a consistent means of recording young doctors' developmental activities. This enhances organisational governance

and assurance and supports high quality patient care.

Turkey-Croatian Exchange Program

Renata Pavlov¹, Özden Gökdemir², Ülkü Bulut³, Olgu Aygün⁴, Dilek Güldal², Mladenka Vrcic Keglevic⁵, Okay Başak⁶

¹Family Practice “Dr. Renata Pavlov”, Zagreb, Croatia

²Dokuz Eylul University, Faculty of Medicine, Department of Family Medicine, Izmir, Turkey

³Public Health Center, İzmir, Turkey

⁴Family Health Care Center, Izmir, Turkey

⁵Foundation for the Development of Family Medicine in Croatia, Zagreb, Croatia

⁶Adnan Menderes University School of Medicine, Aydın, Turkish Association of Family Physicians, Turkey

Background & aims

It's becoming more and more obvious that Vasco da Gama exchanges are achieving extraordinary results. But, for more experienced GPs, some similar programs still don't exist in Europe. Therefore, Turkish Association of Family Physicians and Foundation for the Development of Family Medicine in Croatia have started discussion about project of mutual collaboration including exchange programme aimed to the experienced GP. Aims of Turkey-Croatian Exchange were defined as giving opportunities to working GPs to visit and observe each others daily works and to discuss strengths and weaknesses of GP/FM in both countries, as well as making opportunities for future collaboration.

Method

The Program is planned to be achieved as individual or group exchange, depending of interests and possibilities of both countries. Preliminary content was planned and tested during Zagreb exchange.

Results

Six Turkey's GPs, including two academics, spent four days (10-13.12.2014) in Zagreb. The first day was orientation day, discussion about similarities and differences of health care systems, organisation and functioning of GP/FM, medical education, especially those related to GP/FM (undergraduate and speciality training) and quality improvement in both countries. Turkish colleagues spent two days observing daily work of Croatian GPs in city and rural practices. They participated at the Foundation's Day, mini symposium, giving presentations of the present state and future challenges of GP/FM in Turkey. They also took part in discussion about Croatian's presentations of their research work. City of Zagreb with its cultural heritage as well as accompanying and making friendship was very important part of exchange.

Conclusions

It was exiting experience of meeting, discussing and making friendships with colleagues. Several small projects, including this presentation were planned for future collaboration.

Types and Content of CME Events in Primary Health Care in Federation of Bosnia and Herzegovina

Zaim Jatic¹, Dragana Niksic², Dzanana Jatic³, Olivera Batic Mujanovic⁴, Bakir Mehic⁵

¹Faculty of Medicine University of Sarajevo, Family Medicine Department

²Faculty of Medicine University of Sarajevo, Social Medicine Department

³Public Institution Health Centre of Sarajevo Canton, Ward Family Medicine

⁴Faculty of Medicine University of Tuzla, Family Medicine Department

⁵Faculty of Medicine University of Sarajevo, Internal Medicine Department

Background & Aim

Continuing medical education (CME) is ethical obligation of doctors that significantly affect the quality of provided health care.

Analysis of most common type of CME activities in primary health care (PHC) in Federation of Bosnia and Herzegovina. Comparison of the degree of satisfaction with the CME events between family doctors and other primary care physicians

Methods

A cross sectional study with self-administered questionnaire (n=500) was send to randomly chosen primary health physicians from n=42 municipalities in Federation of Bosnia and Herzegovina.

Results

Total of n = 371 physicians answered questionnaire. Family physicians were n=253 (68%). Content of CME is mostly related to theoretical knowledge (88%), which was often presented in the form of lectures for large groups. Clinical skills were the least represented in the content of CME (47%). A high percentage (90%) of physicians stated that the presence of the CME led to their comprehensive improvements. Family doctors statistically significantly had more training in teamwork (69%), communication skills (79%) and management skills (68%) compared to other PCH doctors. Family physicians were significantly more satisfied with the CME topics [p = 0.006]

Conclusion

Lectures for a large group are the most common form of CME with mainly theoretical content. Family physicians had more CME events with teamwork, communication skills and managerial skills content. They are also more satisfied with CME topics. Clinical skills were the least represented content on CME events.

Systemic Arterial Hypertension combat: a daily fight

Ana Rosa Murad Szpilman, Bethânia Peccini Barros, Camila Pedruze Machado, Daphne Rios Viana, Lais Silva Neves Santos, Rafaela De Paula Souza, Rayza Montovani Siloti
Department of Public Health, Vila Velha University, Vila Velha, Brazil

BACKGROUND & AIM

The information spread on life quality and prevention measures improvement, contribute to decrease the Hypertension incidence and complications. Vila Velha University Medical students with the Brazilian Society of Endocrinology and Metabolism performed an educational campaign on promotion of health for hypertensive patients. The aim of this activity was knowledge acquisition, through a variety of situations, granting professional and personal growth, besides allowing the public to acknowledge this clinical condition with high prevalence as a possible controlled disease.

METHODS

The campaign, performed by the students, took place in a Sunday on Vila Velha beach boardwalk, in Brazil. The students were enabled to carry out arterial blood pressure measurements, capillary blood glycaemia and anthropometrics measurements, activities targeted to adult population, in order to orient the ones with decompensated measurements. The participants answered a form elaborated by the project coordinators to test the population knowledge on hypertension. A pamphlet distribution with simple information was used to inform the population about Hypertension and its consequences. In addition, there was a stretching class for the participants and students.

RESULTS

Around 200 people participated in these activities, and were alerted about the cardiovascular diseases risks and informed about the importance of life habits changes. During the morning, 30 people also participate on the stretching class performed by the Physical Education teacher. There was a great project acceptance by the population, and for the involved group performing the activity, it was possible to achieve the expected feedback.

CONCLUSIONS

The campaign was important to alert the population about the importance of healthy life habits, which besides preventing diseases, also improve the life quality. Therefore, to improve Systemic Arterial Hypertension control, it is essential to be aware of the risks and be motivated to perform a life style change.

Keywords: Hypertension, Quality of life, Public Health, Delivery of Health Care.

Blood Pressure Measurements

The students are measuring the population blood pressure during the campaign.

Form Application

The students are asking questions to the population in order to fill in the information required by the Campaign form.

Medical Students

The Vila Velha Medical Students who performed the Systemic Arterial Hypertension Campaign supported by the Brazilian Society of Endocrinology and Metabolism.

Stretching Class

The participants during the stretching class performed by the Physical Education teacher in the morning.

Increase in residency scholarly activity as a result of resident-led initiative

Kyle Hoedebecke

Department of Family Medicine, Womack Army Medical Center, Ft. Bragg, USA

BACKGROUND AND OBJECTIVES: Scholarly activity (SA) is a fundamental component of family medicine residency training. Despite the variety of SA options, the output of resident presentations and publications remains disappointingly low, and many residents voice frustration with fulfilling the research requirements. A resident-driven process improvement project was undertaken with the goal of achieving a 100% increase of peer-reviewed publications and scholarly presentations by residents with secondary goals of doubling the involvement of staff, residents, and visiting medical or physician assistant students.

METHODS: This project involves (1) increasing awareness of conferences for scholarly submission, (2) assignment of residents in a resident research team to lead efforts, (3) pairing of interns/students with senior mentors with similar interests, (4) faculty to include one resident on all projects, and (5) monthly SA meetings to track research progress, share ideas, and troubleshoot areas of difficulty. Scholarly totals were compared between the 2011--2012 and 2012--2013 academic years.

RESULTS: The SA goals were achieved on all fronts. The number of resident presentations increased from three to 28 (seven regional, 10 national, and 11 international presentations), and resident peer-reviewed publications increased from two to six when compared to the previous year. Scholarly participation doubled at all levels.

CONCLUSIONS: The authors recommend that other residencies consider promoting increased resident-to-resident scholarly mentorship, early planning with scheduled timeline, and increasing awareness of SA opportunities yearly.

Keywords: residents, medical education, scholarly activity, research

Resident Scholarly Submission Totals

Figure 1: Resident Scholarly Submission Totals

The 2012–2013 SA goals were achieved on all fronts. Overall resident scholarly submissions greatly increased as shown in Figure 1. Of the 28 accepted presentations, there were seven regional, 10 national, and 11 international events. Additionally, resident peer-reviewed publication totals increased from two to six, including three case reports, two review articles, and an original research project.

P-0928

Medical Students Knowledge and Perception regarding Complementary and Alternative Medicine

Firdous Jahan¹, Mustafa Manhal Al Ward¹, Muhammad A Siddiqui², Maryam Abdul Jabar¹

¹Oman medical college, Oman

²Queen Margaret University, Edinburgh, UK

Introduction

The purpose of the study was to assess the knowledge and perception of medical students regarding complementary and alternative medicine therapy (CAM). CAM therapies have the potential to increase well-being and thus influence pain. They are often employed in addition to conventional treatments. Patients presents in primary health care usually do self medication with herbs and other CAM so, there is a great need for continuing education on these alternative options in medical curricula.

Methods

A cross sectional survey based study carried out on 6th and 7th year medical students(clinical years). Data was collected on self-filled questionnaire. Statistical analysis was performed using SPSS (IBM SPSS Statistics 20.0). Data were expressed in frequencies, mean and percentages.

Results

Response rate was 76%. Majority of the students (80.5%) were Omani 45% (n-53) of study participants were below 25 years in age and 85.6% (n-101) were female. No difference was observed between 6th and 7th year students (p-0.516, 95% CI -1.74-3.31), significant difference (p-0.009, 95% CI 1.25-8.44). Significant difference was observed (p-0.009, 95% CI -7.45-1.08) between Omani and non-Omani participants. Students have adequate knowledge about CAM and positive approach in clinical practice but over all they have poor knowledge about herb as pain killer.

CONCLUSION: Medical students demonstrated limited self-reported knowledge of CAM and its practices.

GP Training in the United Kingdom: Reflective practice and use of ePortfolio from a trainee perspective

Cemal Kavasogullari¹, Isabella Roiatti²

¹NHS Education Scotland

²NHS Lanarkshire

Background and Aim

ePortfolio is one of the three main constituents of the Royal College of General Practitioners (RCGP) Training Curriculum for general practice. ePortfolio can facilitate reflective learning and enable trainees to develop as mature self learners (1). Authors present their personal experiences of using ePortfolio providing examples of reflective learning entries and how these are utilized in developing reflective practice. Up to date information on the current GP training tools used in the United Kingdom is discussed.

Method

Explanatory guidance on ePortfolio entry and assessments has been obtained.

GP curriculum and information on reflective practice obtained from RCGP Training curriculum.

Excerpts from authors' ePortfolio entries from the first and the last 6 months of training in hospital posts have been analyzed in order to identify changes in practice.

Entries from different reflective learning tools have been compared to identify objective markers of learning and progress in education. Pathways and links between entries have been mapped to demonstrate how reflective practice augments curriculum coverage.

Results and CONCLUSIONS:

As a foreign medical graduates from Hacettepe University Faculty of Medicine, Turkey and Università degli Studi di Verona, Italy respectively, authors report initial difficulties in adapting to ePortfolio and its tools. Reflective practice has been challenging to incorporate into clinical practice at first but authors demonstrated continued progress during comparison of early and late entries. Experienced trainers' roles in facilitating the learning process is found to be essential in the adaptation process.

Albeit there certainly is further scope for improvement particularly with respect to the user interface of ePortfolio, it is recognized as an effective tool for assessment and record of learning. Use of ePortfolio and reflective learning empowers the trainee as a self-directed learner by giving ownership very much back to the learner.

Patient Education in Home Care Services

Kenan Topal¹, Çiğdem Gereklioğlu², Tuba Dilek Ateş¹

¹Adana Numune Training and Research Hospital, Department of Family Medicine, Adana/Turkey

²Başkent University Medical Faculty, Department of Family Medicine, Ankara/Turkey

BACKGROUND: Home care primarily targets to meet the health and social needs of people in their own homes. This concept defines a care system which provides the maintenance of preventive, curative and rehabilitative care and support the current health services. Therefore primary care physicians should be aware of home care. Education is defined as "the process which makes intentional changes in the behaviors of an individual through his/her own living". Education of the patient, family and caregivers is of great importance for maintenance of care.

MATERIAL-METHOD: The most important feature of health education is participation of the subject in his/her health applications willingly. Patient education is based on patient-centered approach. Not only the physical disorders but also social, psychological and cultural characteristics are addressed as a whole. The patient is evaluated with living conditions, problems, family, physical environment and psychological problems. A well-structured patient education helps them to manage and take responsibility for their treatment and makes it easier to overcome their health problems.

RESULTS: The educations aiming at enhancing knowledge and skills about home care after hospital discharge is important for reducing the anxiety of the patient and the relatives who are far from the safety of professional care at the hospital. The educations should be tailored for the patient. Assessment of the learning needs is a priority. The subjects should be effectively involved in the learning process and learning by doing should be the main principle.

CONCLUSION: Improving the knowledge and skills of the physicians and the nurses, the regulations for education and support programs for the families and the other caregivers would significantly contribute to the improvement of home care.

Keywords: Primary care physicians, home care, education of patients.

New Way To Correct Contextual Errors: Making Family Tree

Sultan Oksuz Zortul, Esra Pektas, [Ozlem Ozer](#)

Department of Family medicine, Ataturk University, Erzurum, Turkey

The cornerstones of primary health care are access, equity, essentiality, appropriate technology, multisectoral collaboration, community participation and empowerment. Family medicine deals with people and their problems in the context of their life circumstances, not with impersonal pathology or “cases”. The starting point of the process is the patient. The common denominator is the person with their beliefs, fears, expectations and needs so it deals with health problems in their physical, psychological, social, cultural and existential dimensions in the aspect of community and between disciplines. The discipline has to recognise all these dimensions simultaneously, and to give appropriate weight to each. Physicians' lack of attention to patient's contextual information, such as transportation needs, finances, literacy, or caregiving, can lead to contextual errors complicating medical care. In contrast to biomedical errors, which are not patient-specific, contextual errors represent a failure to individualize care. To exclude the contextual errors, it is important to know patient's environment or behavior that are essential to planning appropriate care. Also it is a component of continuity of health care, longitudinal care and holistic approach. Thus records have key importance from past to now. A good way for recording, making family tree. Family tree is used by genetic counselors and other medical professionals to assess families and try to spot patterns or indications which may be helpful in diagnosing or managing individual's health. The family tree includes some knowledge as family members, whether individuals are living or deceased, date of death, cause of death, medical conditions. smoked, diet or exercise habits, origin of family, if known, should be indicated below the symbol. Families with inherited diseases are widely used in Mendelian/complex disease studies. Family genome analysis, including determination of parental origin of the variants, detection of de novo mutations, identification of potential recombination events.

Keywords: Contextual errors, contextual care, family tree,

Innovation in Postgraduate Training for Primary Care of the Future: A Singaporean Perspective

[Julia Hui Li Ong](#), Grace Huiting Lum, Boon Yeow Tan

Division of Family Medicine, Department of Medicine, National University Health System, Singapore

Much like many developed countries, Singapore's primary care system is anticipating a silver tsunami with a rapidly ageing population. Moreover, her small size with hospitals within 5-15 minute access of each household results in many with chronic disease having multiple specialist appointments with reduced transfer of care back to family physicians. This has resulted in fragmentation of the healthcare system with reduced ownership of care.

The Family Medicine Residency Programme introduced in 2011 has given primary care a new stake in postgraduate training and aims to train family physicians to suit Singapore's needs. We share current innovation in our Residency training and envision possibilities for the future.

Innovative measures include the use of Information Technology (IT) to tag patients to residents. Patient admissions are flagged up to residents electronically, providing opportunities to contribute to inpatient care and support care after discharge, reducing the need for numerous specialist appointments. Family Medicine Residents also go on call allowing patients to get in touch with a primary care physician round the clock. Residents also work across many settings including inpatient, specialist outpatient clinics, community hospitals, nursing homes and home visits, attempting to attain a comprehensive grasp of the kind of care patients might typically go through.

As residents who have experienced how IT has helped reform our contribution to care, we look to the future of primary care and envision possibilities. These include increasing the autonomy of personal electronic health record which patients can access at all times, teleconferencing with inpatient teams and having instant messaging

capabilities that can improve bidirectional communication. The goal is to allow patients to understand their care better and bring back the ownership of each patient by a family physician.

Keywords: Residency, Information Technology, Primary Care

All Cases

Benefits	Number of Residents who reported this benefit	Quote from residents' answers
To build rapport with my patients	4	"Having visited patients in hospital brings a deeper element to doctor - patient trust."
To anticipate follow up steps after discharge (e.g. home visit)	2	"I would be able to arrange for follow up/home visit if I note issues during admission that I think needs to be sorted on discharge"
To improve communication with Specialists	1	

Unexpected admissions

Benefits include:	Number of Residents who reported this benefit	Quotation of residents' answers:
To reflect about the consultation process	8	"It allowed me to follow up on patients and realise if I missed any red flags or differentials"
To learn inpatient management of the issues	5	"Enabled me to learn from specialist management"
To understand potential problems patients face	2	"It allowed me to better appreciate how my patients' clinical conditions and social circumstances evolved after the clinic consultation. Their admissions were usually due to an acute exacerbation of a chronic disease, or in some cases, caregiver stress and breakdown of social support.""
To understand the importance of preventive medicine	1	

Expected Admissions

Benefits include:	Number of Residents who reported this benefit	Quotation of residents' answers:
To learn whether the referral was warranted	2	"For patients that we suspected something was wrong and acted on it, we can review and see if our suspicion was correct"
To check if patient defaulted	1	

P-0933

Concept identification and context analysis of the Wonca Europe 2015 book by instance-based categorization of general practice activities

Marc Jamouille¹, [Carl Steylaert](#)²

¹Dep. of General Practice, University of Liege & Wonca International Classification Committee

²WONCA Europe Hon Treasurer

Context:

Family physicians are large producers of knowledge. The site of Wonca Europe provides access to almost 20,000 abstracts produced by family physicians since 1995 (from Europe) and 1998 (from World Conferences). On the occasion of 20 years of Wonca Europe, an editorial committee selected 100 of the best abstracts and has asked each author (or a substitute) to make a chapter for the Wonca Book published in 2015 at the Wonca Europe congress.

The content analysis of medical texts is generally achieved by the use of MeSH. To fill gaps in MeSH, a specific family medicine classification has been developed under the name Core Content Classification of General Practice / Family Medicine (3CGP). A combination of ICPC + Q-Codes (new tool for non-clinical items) provides just fewer than 900 concepts for analyzing the contents of specific texts to family medicine.

METHOD:

The 100 chapters of the Wonca Book 2015 were analyzed using 3CGP by a single observer not involved in the editorial committee of the book. Every text has been carefully read and a maximum of two concepts by chapter were reported in an Excel spreadsheet.

RESULT:

150 codes were used of which 143 from the classification of non-clinical items Q-codes and 7 coming from ICPC. Among the topics discussed by authors and identified by Q-codes, 35 relate to knowledge management which includes family medicine education, 29 codes concern research and development, 29 doctor's specific area, 24 patients' issues, 11 relate to the structure and 8 deal with ethics.

DISCUSSION:

Despite limitations (unique observer – not validated tools) the study reveals striking facts. The editorial board has favored themes that affect the structure and organization of knowledge of the profession. Clinical items or affecting directly the patients are very poorly represented. More about 3CGP on <http://docpatient.net/3CGP>

P-0934

Medical Student Assessments' of Patient and Doctor Perspective

Serkan Yavuz, Nilgun Ozcakar

Department of Family Medicine, Dokuz Eylul University, Izmir, Turkey

Background & Aim

Doctor-patient interview is the basis of medical practice. Purpose of interview is to understand patient's problem and resolve in light of physician's medical knowledge. In an effective interview, doctor should be able to evaluate patient perspective in addition to his own for better communication. Disease influence on individual's life, relationships and their expectations must be learned.

Methods

In this study 3th year medical students observed physician-patient interviews at outpatient clinics. They filled physician perspective forms evaluating communication, history and physical examination, patient perspective forms accompanied by patient as long as they were in clinic. Totally 237 forms were analyzed by content analysis.

Results

Students assessed physician perspective "simple language used(70/128)", "communication fine(22)". Oriented main complaint while taking history(29), answered patients' questions(11), given explanatory answers, 9 didn't give answers. Some(13) had never done physical examination, 49 was intended for complaints.

Patient perspective forms(109) evaluation determined patients were in three different situations:

Conditions presented as "intense anxiety" described by "Patients have intense anxiety starting one day before the appointment described as 'If something goes bad'.

"He says not been given enough information about treatment. When problems occurred not know when to stop drugs" as "negative",

And as "positive" as "Family happy with the hospital, doctors give enough time to each question of mother, indicate that giving interest and clear answers create these feelings".

Discussion & Conclusion

In doctor-patient interview while issues doctor decide prior to know, patient has a different agenda including social conditions, health perceptions. The difference effectuates dysfunctional exposes while diagnosis, treatment and follow-up are negatively affected.

For lasting relationship aiming medical disciplines such as family medicine understand patient is important as understand the disease and diagnose. Developing applications for behavior and attitudes of physicians at patient interviews should take place in curriculum of medical schools.

A mixed methods study of psychiatry trainees investigating the factors in their undergraduate medical training which may have contributed to their decision to train in psychiatry

Amber Appleton, Marta Buszewicz

University College London, Department of Primary Care and Population Health

Background and AIMS:

For years psychiatry has been undersubscribed as a career choice. Undergraduate psychiatry teaching is likely to impact on this. Some medical schools have integrated psychiatry with other specialities to reduce separation in future doctor's minds between mental and physical health. The optimal undergraduate psychiatry curriculum needs to be established.

Aims:

- (i) To improve understanding of how the psychiatry curriculum impacts recruitment in this speciality by examining the trainees' perspective
- (ii) To make recommendations for a universal undergraduate psychiatry curriculum to enhance positive attitudes towards mental health.

METHOD:

A mixed methods qualitative study with two parts:

- i) Web-based survey of all psychiatry trainees (in London initially then nationally) to ascertain the trainees' perspective on undergraduate teaching. We will ask which medical schools they trained at, and this will be triangulated with a complementary study documenting the psychiatry curriculum at different medical schools
- ii) In-depth interviews with purposively sampled trainees to explore their views on their undergraduate mental health teaching

RESULTS:

From London, we have had 172 trainee responses (29% response rate), from a range of 26 UK medical schools. Provisional results show that 85% of trainees were taught psychiatry in blocks at medical school; however 68% thought psychiatry teaching should be integrated throughout the curriculum. 69% said their attitudes towards psychiatry changed after being taught psychiatry at medical school. 80% decided on a career in psychiatry during or after medical school, and 50% said the teaching they received at medical school influenced their career choice in psychiatry. This highlights the importance of developing an optimal psychiatry curriculum to capture the interest of medical students in this speciality.

Conclusions

Data collection is still in progress with the survey being sent nationally and interviews about to commence. This will be all completed by August 2015 and final results presented.

Keywords: Education, Curriculum, Psychiatry

Figure 1: Do you think psychiatry teaching should be integrated throughout the Medical School curriculum?

85% of trainees were taught psychiatry in a block. However 68% strongly agreed or agreed that it should have been integrated throughout the undergraduate curriculum.

Figure 2: When did you decide on choosing psychiatry as a career?

80% decided during or after medical school; highlighting an important group to target at medical school by optimizing teaching of psychiatry.

Figure 3: Did your attitudes change after being taught psychiatry?

69% of the trainees said they noticed their own attitudes towards mental health changed after being taught psychiatry.

Figure 4: Did the teaching you received influence your decision to choose a career in psychiatry?

56% agreed or strongly agreed highlighting the importance of optimizing the teaching of psychiatry at medical school

Figure 5: Was there an individual at Medical School who influenced your decision to choose psychiatry?

39% said there was an individual at medical school who influenced their decision to choose psychiatry as a career

Figure 6: Suggestions from trainees for improving psychiatry teaching at medical school

“More integrated”
“More of it”
“Mentoring”
“More emphasis on liaison/organic psychiatry”
“Dynamic teachers”
“Balint groups”

The trainees were asked what they suggested would help improve teaching of psychiatry at medical school and some of the key suggestions have been summarized in this figure.

Figure 7: Suggestions for improving recruitment to psychiatry

Improving psychiatry services
Overcoming stigma (in media and among colleagues)
Highlighting that psychiatric treatment is evidence-based
Emphasize breadth of psychiatry
More engaging medical school placements
Improving relationship with other specialties

The trainees were asked for their ideas for improving recruitment into psychiatry as a career and these have been summarized in this figure.

The Immunization Working Group - SIG of the Romanian National Society of Family Medicine (SNMF)- activity and future projects

Sandra Adalgiza Alexiu, Gindrovel Dumitra, Daniela Ștefănescu, Cristina Vasilica Barbu, Dorica Sănduțu, Maria Lup, Dana Ștefana Popescu, Mădălina Vesa, Anca Deleanu

Immunization Working Group, National Society of Family Medicine, Romania

In Romania GPs are the main vaccinators. The Immunization Working Group was born as a consequence of the desire of GPs to be aware of the latest news in the field and to help increase vaccination coverage. The group consists of GPs certified as trainers, experienced in setting up and conducting CME programs for GPs and specialized in vaccinating infants, children and adults.

Established in 2012, the group structured programs for various categories of patients, media, GPs. Partnerships with the organizers of the most important medical events that address issues related to vaccination have made possible many activities of the group in the 3 years since. Today, members of the group are asked to contribute to future projects regarding vaccination, training programmes for implementing new vaccines in the National Immunization Schedule and a new vaccination national law. Currently SNMF believes that the appearance and evolution of this Special Interest Group had a beneficial effect on quality of care in family medicine and aims to promote the development of other SIGs.

We want to share the experience of our group with our colleagues in Wonca through a breakdown of the activities carried out by the group (workshops, symposia, debates, media/social media campaigns for patients&GPs, World Immunization Week in partnership with the WHO Country Office, attending ESPID and WONCA-Europe conferences, translation and adaptation of guidelines for improving protection through immunization).

Our future projects include new CME projects for our Romanian colleagues, working with other countries on the issue of immunization as part of primary prevention, building an international Wonca network for GPs on immunization subjects.

We invite GPs from other countries where they are the main vaccinators to work with us in joint CME projects or campaigns for professionals and the general public.

¹The Clinic of Family Medicine, Ankara Training and Research Hospital, Ankara

²Department of Family Medicine, Faculty of Medicine, Hacettepe University, Ankara

³Department of Family Medicine, Faculty of Medicine, Eskişehir Osmangazi University, Eskişehir

""AIM: to determine if the final year students of the faculty of medicine of Eskişehir Osmangazi University (ESOGU) feel themselves enough about obstetric and gynecologic diseases that they are going to frequently face during primary care practice.

MATERIALS-METHOD: This survey was applied to the last year students of the faculty of medicine of ESOGU within 2011-2012 and 2012-2013 academic years. The study was performed just one month before their graduation. Survey included questions about adequacies about diagnosis, treatment and the referral criteria of obstetric and gynecologic diseases. They were asked yes/no questions.

RESULTS: A total of 203 students answered the questionnaire. Of them, 50,7 % were female, 49,3% were male. Results are given in the table below.

Frequently Seen Obstetrics and Gynecologic Diseases in Primary Care Can diagnose, Can treat/ Can perform intervention, Knowledge about referral criteria

Sexually transmitted disease 70,0 53,2 42,9

Normal pregnancy 94,6 54,2 60,6

Hyperemesis gravidarum 78,3 49,8 45,8

Postpartum hemorrhage 79,8 36,0 43,8

Urinary tract infection 97,5 97,5 70,4

Pelvic inflammatory disease 44,3 29,6 32,0

Vulvovaginal candidiasis 69,0 63,1 39,4

Eclampsia 60,1 27,1 36,0

Pre-eclampsia 62,6 27,6 36,0

Iron deficiency anemia 97,0 94,1 71,9

Dysmenorrhea 95,1 87,2 58,1

Breastfeeding problems 54,2 43,8 36,0

It was observed that the students feel themselves most adequate in the management of urinary tract infection.

CONCLUSION: Obstetric and Gynecologic diseases are among the mostly encountered diseases in primary health care practice. Primary care physicians should recognize, should be able to treat and should be able refer if necessary. If not, consequences such as serious disabilities, leading also to increase in the cost of treatment, may occur. Education in this field should be revised, and some opportunities should be given to the students to have more practice on the topics in which they feel themselves inadequate"".

Greek general practice residents' perceptions on their educational environment, using the Postgraduate Hospital Education Environment Measure (PHEEM): comparison with other specialties

Vasileios Trifon Karathanos¹, Vasileios Nikolaos Kiosses¹, Persa Koutsogiannou², Eleni Jelastopulu², Ioannis Dimoliatis¹

¹Department of Hygiene and Epidemiology, Medical Education Unit, University of Ioannina, Medical School, Greece

²Department of Public Health, Department of Public Health, Patras, Greece

BACKGROUND:

To record general practitioners' (GP) perceptions on educational environment in Greece and to compare with other specialties.

Summary of work:

Residents from all over Greece answered the PHEEM questionnaire. Mean total score was calculated for all participants and for specialties, and compared using t-test. Scores are given in the standard 0–100% scale. An educationally minimum important difference (EMID) of 5% was accepted.

Summary of RESULTS:

Out of 731 residents, 27% were general practitioners (GPs), 34% internists, 22% surgeons, 12% lab specialty (labs) and 5% other. The total PHEEM mean score for all participants was 41.1, for GPs 37.6, for internists 41.5 ($p=0.003$ versus GPs), for surgeons 42.7 ($p<0.001$), and for labs 45.1 ($p<0.001$). Mean differences were 3.9 (internists-GPs), 5.1 (surgeons-GPs), and 7.5 (labs-GPs), i.e., less than one, one, and one and a half EMID, respectively. Compared to all other residents, GPs were less satisfied with specialty exams (24.6 vs. 36.7, $p<0.001$) and their expectations when entering the medical school less fulfilled (32.4 vs. 35.1, $p=0.016$).

CONCLUSIONS:

Residents aren't satisfied with their post and education, only about 40%, a perception perhaps confounded by country's current negative socioeconomic conditions. Although mean scores for all specialties lie within one EMID around total mean score for all participants ($41\pm 5=36-46$), GPs perceive their educational environment as poor (within the 25-39.9% interpretation zone) while the other three specialties as rather poor (within 40-49.9%).

Take-home message:

There is an urgent need for drastic redesign of the residency programs in Greece to improve the educational environment and increase the quality of and satisfaction with the training, especially for GPs.

⁴Dokuz Eylül University Medical Faculty Department of Family Medicine, İzmir, Turkey

⁵Tepecik Education and Training Hospital Family Medicine Clinic, İzmir, Turkey

⁶Umraniye Education and Training Hospital Family Medicine Clinic, İstanbul, Turkey

BACKGROUND and AIM:

Vasco da Gama Movement (VdGM) Exchange group is a sub-working group of VdGM arranges exchange programmes between young General Practitioners (GP) from European countries. VdGM Conference Exchange Programmes are frequently organized in most of the participating countries but it has not been organized in Turkey before.

Our aim was to introduce Turkish primary health care system and to develop socio-cultural relations between young GPs by organizing the First Turkish Conference Exchange Programme.

METHOD:

VdGM Turkish Team organized the exchange programme in May 2015 before the 14. Eastern Mediterranean Family Medicine Symposium in Adana by the collaboration with the host organizing committee of the symposium. Five participants from four countries were accepted to the programme (Marieke Leemrize from Denmark, Phillippe Eren from France, Ines Gonzalez Bolanos from Spain, Alexandro Pinho and Raquel Salgado Sousa from Portugal) During the exchange programme, Cukurova University Hospital Family Medicine Department, Balcalı Education and Training Hospital, Cukurova Mehmet Ali Kirac Urban Health Care Centre, Sarıcam Mehmet Akif Ersoy Rural Health Care Centre, Sarıcam Maternal and Child Health Care Centre, Adana Nursery Home, Tarsus American Colledge School Health Care Centre were visited to observe Turkish primary care and family medicine. May 19th World Family Doctor Day was celebrated by Turkish GPs and exchange participants with a special boat tour on Adnan Menderes Dam Lake.

VdGM Workshop titled "Young Side of Family Medicine" was held in the symposium with the participation of WONCA Europe President, Turkish Association of Family Physicians President, academics, GPs and GP trainees. Presentations introducing primary healthcare systems of different countries were made and all participants shared their experiences during this workshop.

RESULT:

The First Turkish VdGM Conference exchange had a goal of providing a better understanding in different primary health care systems and cultures among young GPs and GP trainees.

Establishing the Family Medicine Training Programme in Palestine

Nawal Abusarhan¹, Walid Tarda¹, Israa Alassa², Lubna Alsaudi¹, Charilaos Lygidakis³, Paul Wallace⁴

¹Faculty of Medicine and Health Sciences, An-Najah University, Nablus, Palestine

²Primary Healthcare Beitlehem, Beitlehem, Palestine

³Vasco da Gama Movement

⁴University College London, UK

Background & Aim

The development and implementation of Family Medicine (FM) in the Palestinian West Bank has faced significant obstacles due to isolation and the consequences of military conflict. The first trials for introducing the concept of FM date back in 1993, while in the past there were attempts to provide short training by the Medical Aid for Palestinians (MAP-UK) and WHO.

Led by Dr Samar Musmar, the first postgraduate FM training programme in West Bank was launched in the An-Najah University in Nablus 2010. The objective of this presentation is to illustrate its organisation and explore its next steps.

Method

The curriculum includes various rotations such as in paediatrics, emergencies and psychiatry. Although a 15-month rotation in FM is mandatory, due to the lack of Family Doctors, the residents work in clinics, staffed by untrained Generalists and other specialists. Support to the programme has been provided by the International Development of Family Medicine in Palestine (IDFMP) initiative, which is a collaboration between academic General Practitioners and is endorsed by WONCA EMR and WONCA Europe.

Results

The first cohort of residents undergoing a comprehensive four-year training consisted of 24 physicians, all at different stages of career –from recently qualified to long established; 8 of them graduated in December 2014. The Ministry of Health has supported the establishment of 3 pilot Family Medicine Clinics in Hebron, where the FM graduates have permanent place of work, while it plans to operate specific clinics with tutors in FM. Finally, the IDFMP initiative is becoming embedded as an international academic programme, aiming at offering international exchanges, mentorship and personal/online support.

Conclusions

Although the launch of the FM training programme was carried out under extremely challenging circumstances, it still represents a significant step for the improvement of the Primary Care services in Palestine.

A survey to evaluate our physicians' clinical experience regarding the bisphosphonate-related osteonecrosis of the jaw

Lana El Osta, Sara Lakiss, Reine Tannous, Maria El Gemayel, Nada El Osta

Department of Public Health, School of Medicine, Saint-Joseph University, Beirut, Lebanon

BACKGROUND AND AIM: Clinical trials have demonstrated the efficacy of bisphosphonates for the treatment of metabolic and oncologic bone disorders. Various safety issues that were not noted in these trials have, however, now emerged with post-marketing surveillance and increasing clinical experience, such as the bisphosphonate-related osteonecrosis of the jaw (ONJ).

This study aims to evaluate the clinical experience of our physicians with regard to this rare complication.

METHODS: We conducted an observational cross-sectional survey at our hospital in 2014. Data were collected through an anonymous, structured and self-administered questionnaire distributed to 190 eligible physicians in the departments involved in prescribing bisphosphonates and in managing the ONJ.

RESULTS: One hundred thirty six valid responses were obtained (response rate: 71.6%). More than half of the participants (63.2%) were treating patients with bisphosphonates: the most prescribed form being the weekly oral bisphosphonates for osteoporosis followed by the zoledronate several times yearly for malignant bone diseases. Only 35 (25.7%) physicians had the opportunity to examine a necrotic bone of the jaw, and 21 (15.4%) to treat and/or participate in the treatment of a necrotic bone of the jaw during their careers and/or their medical studies; ear nose and throat surgeons and oncologists rather than other specialists (p-value <0.0001). Eighty-five participants (62.5%) were aware of bisphosphonate-related ONJ, and 65 (47.8%) fear this complication. There were statistically significant associations between the awareness/fear and physicians' specialty, whether or not they prescribe a bisphosphonate, whether or not they have observed and treated exposed necrotic bone of the jaw among patients (-p-value<0.05).

CONCLUSIONS: Given the large and growing number of patients receiving a bisphosphonate, it is likely that physicians may encounter some patients with bisphosphonate-related ONJ, which has been shown by our study. Further studies assessing the application of ONJ preventive measures on patients treated with bisphosphonate are required.

Measuring deprivation in final-year medical students in a Greek University

Emmanouil Smyrnakis, Evaggelia Tsiga, Magda Gavana, Stathis Giannakopoulos, Alexis Benos
Laboratory of Hygiene, Department of Primary Health Care and General Practice, Medical School, Aristotle University of Thessaloniki

Background - AIM:

Economic crisis in Greece lead to considerable cuts in universities' funding. As a consequence the Department of Primary Health Care (PHC) and General Practice (GP) of the Aristotle University of Thessaloniki (AUTH) Medical School was forced to stop transportation and accommodation reimbursement for final year medical students that had to attend PHC and GP attachment in rural health centers. The aim of this study was to evaluate students' deprivation status in order to understand if they can stand this additional financial burden. The research questions are: How economic crisis affects material, social and health deprivation in final-year medical students? Is there a difference in deprivation status between two sequential academic years?

METHOD:

A cross-sectional study was conducted using the 'Deprivation in Primary Care Questionnaire' (DiP-Care-Q). All final-year AUTH medical students were asked to complete the Dip-Care-Q at the first day of their PHC and GP attachment during two sequential academic years. Material, social, health and overall health deprivation indexes were calculated.

RESULTS:

487 final-year medical students participated in the study (41.9% and 58.1% from the academic years' 2012-13 and 2013-14 respectively). The mean scores were: material deprivation index (M=2.13, SD=1.37), social deprivation index (M=0.75, SD=0.85), health deprivation index (M=0.25, SD=0.55) and overall deprivation index (M=1.2, SD=0.52). Statistical significant differences were observed between the two academic years for material deprivation (p=0.001) and overall deprivation index (p=0.013), with highest deprivation occurring at 2012-13 cohort.

CONCLUSIONS: According to the results of this study, economic crisis affects material deprivation in medical students of AUTH Medical School. Even though deprivation indexes (material and overall) seem to become better through the two academic years, it's extremely crucial to restore universities funding in order to ensure the continuity of education in PHC and GP which is the base a sound public health care system.

Keywords: economic crisis, undergraduate medical education, deprivation

Table 1. DipCare-Q Questionnaire

We would like you to answer the following questions dealing with your personal finances, social environment and general health. Please mark with an X (☒) the answer that best applies to your own situation.

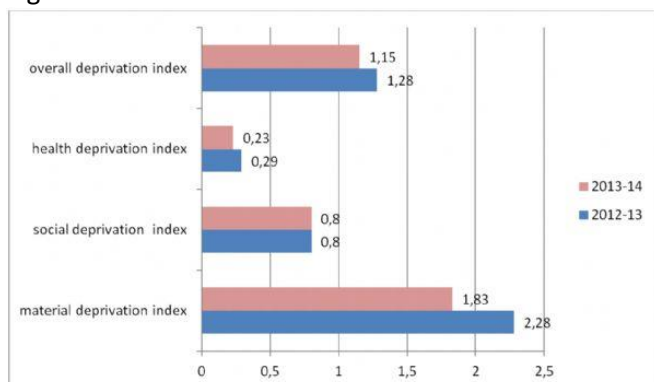

1. During the last 12 months, have you had trouble paying your household bills (taxes, insurance, telephone, electricity, credit cards, etc.)? Yes No
2. During the last 12 months, have you had to ask your immediate family for money to cover your basic day-to-day needs? Yes No
3. During the last 12 months, has a member of your household not sought treatment (dentist, doctor, buying medication) because you didn't have enough money? Yes No
4. During the last 12 months, have you feared being evicted from or losing your home? Yes No
5. During the last 12 months, have you not bought clothes even though you or a member of your household needed them? Yes No
6. During the last 12 months, have you not bought furniture or household goods even though you or a member of your household needed them? Yes No
7. During the last 12 months, have you gone on holiday? Yes No
8. During the last 3 months, have you spent an evening in the company of close family members or friends? Yes No
9. During the last 3 months, have you been to the cinema, the theatre, a concert or a sports event? Yes No
10. During the last month, has there been an occasion when your household did not have enough to eat? Yes No
11. During the last month, have you been able to access the internet (at home, at work, at a library, at an internet café, etc.)? Yes No
12. If you're in difficulty, is there someone outside your household to whom you can turn for material help (money, food, accommodation)? Yes No
13. Are you currently finding it very difficult to pay back money (to the bank, family, friend etc.)? Yes No
14. Do you currently suffer from a physical disability that has a major impact on your day-to-day life? Yes No
15. Do you currently suffer from mental health issues or problems that have a major impact on your day-to-day life? Yes No
16. Do you currently have problems linked to alcohol consumption, drug-taking, gambling etc.? Yes No

Table 3

	cohort	N	mean	SD	p-value
material deprivation index*	2012-13	202	2.28	1.48	0.001
	2013-14	275	1.83	1.45	
social deprivation index	2012-13	201	0.80	0.94	0.990
	2013-14	278	0.80	0.98

Table 2

Instructions for calculating DiPCare-Q indexes

- a) Code all 16 questions (D1 to D16) "1" for "Yes" and "0" for "No".
- b) Recode questions D7, D8, D9, D11, and D12 "1" to "0" and "0" to "1" for all positive items to be related to deprivation.
- c) Generate the following indexes:
 - Material deprivation index: $D1+D2+D3+D4+D5+D6+D10+D13$
 - Social deprivation index: $D7+D8+D9+D11+D12$
 - Health deprivation index: $D14+D15+D16$
- d) Calculating overall deprivation index: DiPCare-Q index
 1. Generate categories of deprivation from the corresponding index:
 - Material deprivation categories: generate the following categories from the material deprivation index: 1 to 2 = 1, 3 to 6 = 2, 7 to 8 = 3
 - Social deprivation categories = social deprivation index
 - Health deprivation categories: generate the following categories from the health deprivation index 0 to 1 = 0, 2 to 3 = 1
 2. Using these variables, compute the overall deprivation index using the following equation for each participant:

$$\text{index} = 0.810 \cdot \text{mat_cat} + 0.455 \cdot \text{soc_cat} + 0.711 \cdot \text{health_cat}$$
 3. Round result to the closest unit ending with an index of 5 levels of deprivation.

Figure 1. DiPCare-Q index

		Health deprivation index (0) 0 to 1 point				Health deprivation index (1) 2 to 3 points				
Social index	0 point (0)	0	1	2	2	0 point (0)	1	2	2	3
	1 point (1)	0	1	2	3	1 point (1)	1	2	3	4
	2 points (2)	1	2	3	3	2 points (2)	2	2	3	4
	3 points (2)	1	2	3	4	3 points (2)	2	3	4	5
	4 points (2)	2	3	3	4	4 points (2)	3	3	4	5
	5 points (3)	2	3	4	5	5 points (3)	3	4	5	5
		0 points (0)	1 to 2 points (1)	3 to 6 points (2)	7 to 8 points (3)	0 points (0)	1 to 2 points (1)	3 to 6 points (2)	7 to 8 points (3)	
		Material index				Material index				
$\text{Overall index} = [\text{material deprivation}] \times 0.810 + [\text{social deprivation}] \times 0.455 + [\text{health deprivation}] \times 0.711$										

Calculation table for the DiPCare-Q index ranging from 0 to 5 using subindexes corresponding to material, social and health deprivation.

P-0943

Teaching medical students in private clinics: can Malaysian General Practitioners deliver?

Norlehan Abdul Samad, Yong Rafidah Abdul Rahman
Cyberjaya University College of Medical Sciences, Malaysia

Background and Aim

Community based training is practiced all over the world in undergraduate medical education. The Malaysian public facilities are stretched to its limit to cater to the increasing number of medical students training and meeting patients' needs. Selected privately operated health clinics are increasingly utilized as teaching place for primary care students. The capability of these private entities to provide effective student teaching is evaluated.

Method

Undergraduate medical students spend a week at private general practitioner's (GP) clinic as part of their 8-week family medicine clerkship. Participating GPs are requested to complete a 5 -point likert-scale questionnaire form at the end of the rotation.

Results

60 forms were returned (73% rate). Most GPs are confident of their ability to teach (85%) but express need for better teaching skills. Teaching medical students improves GPs morale and facilitates reflection on their work (89%). Many GPs (38%) do not wish remuneration but larger proportion (41%) considers it important. Student's presence does not always improve service to clinic and patients.

Conclusions

Private GPs are confident of their ability to provide teaching for undergraduate medical student despite possible setbacks on their practice and patients. Appropriate recognition and support from other stakeholders are necessary for effective implementation. Our finding echoes similar trend in previous GP teaching experiences in other parts of the world. Successful practices from established family medicine training programs can be emulated and adopted.

The Preferences of the Intern Doctors for Medical Specialization, The Features of Their Perspective Towards Family Health Care Stage

Ahmet Yilmaz, Necmi Arslan, Hamza Aslanhan, Gamze Bucaktepe, Erkan Kıbrıslı

Dicle University Medicine Faculty Department of Family Medicine

OBJECTIVE:

In this present study, the variables which influence the specialization preferences, the perspective towards family health care rotation and branch choices of the 6th grade students who attend Family Health Care Department of Dicle University Medical Faculty are tried to be analysed.

METHODS:

80 medical students participated in this cross sectional study. One being for the beginning and one for the ending, assessment forms were applied to the intern doctors when they started and finished their rotations. question form in the observation of a lecturer from a family health care department about their branch choices, socio-demographic features and possible reasons for choosing the preferred departments.

RESULTS:

Average age was found $24,83 \pm 1,5$. 95 % (n=76) wanted to specialise in any area of medicine and 76,1 % (n=61) were actively studying for the medicine specialty exam. 79,3 % (n=46) of these students were male and 68,2 % (n=15) were female (p=0,296). It was reported that 27,6 % (n=16) of the males and 4.5 % (n=1) of the females extended the school for 8-16 weeks while 31 % (n=18) of the males and 9.1 % (n=2) of the females extended the school for 16-24 weeks (p=0.043). It was seen that before the training, 70 % of the intern students (n=56) had the knowledge about the family health care practices and this knowledge came from the lecturers in the rate of 40 % (n=24), from family health care practitioner-good medicine practices in the rate of 26.7 (n=16), from media-and friends in the rate of 25 % (n=20).

Before family health care rotation, the most preferred branches were internal medicine in the rate of 13,7 % (n=10), cardiology in the rate of 12,3 % (n=9), emergency medicine in the rate of 9,6 % (n=7), dermatology in the rate of 6,8 % (n=5), whereas after the rotation internal medicine was 16,7 % (n=13), emergency medicine was 14,1 % (n=11), dermatology was 11,5 % (n=9), cardiology was 9 % (n=7). The least preferred ones were respectively pathology, neurology and radiology. While radiology was in the rate of 1,3 % (n=1) beforehand, it remained the same afterwards. The preference of family health care was in the rate of 4,1 % (n=3) before the training whereas it became 5,1 % (n=5) after the training. When the students were asked the reasons which influenced their choices, it was seen that allocating time to family and private life was 82,5 % (n=66), risk and responsibility was 52,5 % (n=42), compatibility regarding stress was 68,75 % (n=55).

CONCLUSIONS:

It was seen that male students were at the forefront regarding specialization when compared to female students.

In the process of choosing a branch, allocating time to family and private life and enabling a good social life are dominant factors. We believe that our training practices, which is only at its 8th month, should be promotive and practice-theory applications should go on increasingly

The VdGM Hippokrates Programme: how senior General Practitioners can be involved in apart from being hosts?

Rosa Avino, Katrina Whalley, Sara Rigon, Jasna Vucak, Solveig Carmienke, Juan Maria Rodriguez, Dinky De Haseth, Ana Barata, Anna Pawelec, Sheila Loughman, Christofer Patrick Reichel, Elodie Hernandez

Vasco da Gama Movement Exchange group

Background & AIM:

The Hippokrates Exchange Programme has been created for trainees and junior GPs within 5 years from the end of their vocational training. What about involving senior GPs and hosts to actively participate in an international exchange? Are they keen to exit their comfort zone and observe different practices as well as their young colleagues?

The aim of this poster is to present results of a pilot phase of a new informal exchange network amongst Hippokrates host GPs, exploring the feasibility of host-to-host exchanges.

METHODS:

VdGM National Exchange Coordinators (NECs) of participating countries each invited at least 2 Hippokrates host GPs to participate. Hosts were asked to complete a short online questionnaire stating their previous experiences, reasons why interested in host-to-host exchanges, and expectations of the experience.

RESULTS:

Ongoing. First results are expected in the further months.

CONCLUSIONS:

We aim to collect data exploring why senior GP hosts are themselves interested in taking part in international exchange experiences; this is a key step in assessing the demand and feasibility of establishing a host-to-host exchange network.

Perceived Stress and State and Trait Anxiety Levels of Intern Medical Students

Fatma Goksin Cihan, Merve Karademirci, Ruhusen Kutlu

NE University Meram Medical Faculty, FM Department, Konya, Turkey

Background and AIM: During their medical education, students may have to deal with many uneasy situations. The aim of this study was to evaluate the concerns about the post-graduation level besides the current concerns of last year medical students.

METHODS: This descriptive study was conducted by the final year students (n=155) of Necmettin Erbakan University Meram Medical Faculty. Besides sociodemographic questionnaire, the Perceived Stress Scale (PSS-8) and the State – Trait Anxiety Inventory (STAI) was performed by face to face interview technique. The results were analyzed using SPSS 20.0 software for statistical analysis, and minimum, maximum and mean values were calculated, frequency and chi-square tests were used.

RESULTS: Forty nine point six percent of respondents were male. While 61.8% of respondents preferred the medical faculty voluntarily, 19.9% by the encouragement of family, 13% preferred because of job guarantee, 5.3% for prestige. Anxiety levels were high in 45.8% of students. Males (60%) had significantly higher anxiety than the females (40%) ($p < 0.05$). Case presentations, service visits and the lack of practical training were causes of statistically higher perceived stress levels and state and trait anxiety levels ($p < 0.01$). Within students with higher anxiety levels, 42.7% were thinking to drop out of medical school. Of participants with high anxiety levels, 32.8% had indicated that they experienced high levels of anxiety mostly during practical trainings ($p < 0.05$).

CONCLUSIONS: Nearly half of the students had high anxiety levels. Both their anxiety and perceived stress levels were increasing with practical applications on patients. This result underlines the importance of practical undergraduate training methods like role playing, applications on models and simulations. Students should spend more time with patients to overcome their anxiety and feel adequate as a physician.

UK GP Rural Track Training: Out of Programme Experience (General Practice in New Zealand)

Christopher Mulholland¹, Kate Dixon²

¹GP Registrar, Group Practice Stornoway, NES GP Rural track programme, Western Isles, Scotland.

²GP Registrar, Langabhat Medical Practice, Isle of Lewis, NES GP Rural track programme, Western Isles, Scotland

Background

We had a unique opportunity within our UK rural GP training scheme (based in the Western Isles) to have an integrated 6 month out of programme experience (OOPE) in our 3rd year. Having completed our hospital part of training we wanted to experience General practice in a different rural setting; to gain more clinical experience and understand the differences in delivering rural health care between Scotland and New Zealand (NZ).

Content

We will describe our planning experience and give advice to others on how to plan a clinical OOPE. Explore our journey to East Otago Health, including our experience with the fantastic multi-disciplinary team and community. Learn about the Maori population, who experience gross inequalities in health: Higher rates of CHD, diabetes, obesity, mortality. Discover more behind their health beliefs, exploring Māori culture and values.

Impact/Relevance

General practice in New Zealand faces similar challenges to the UK, particularly in terms of delivery of rural health care services, recruitment and sustainability of the workforce.

Key differences between the healthcare systems in the UK vs. NZ include: Private GP healthcare provision, allowing longer consultation times but at the patient cost. Accident Claims Compensation Scheme (ACC), a national scheme whereby healthcare following an accident is subsidised, ACC co-ordinates the rehabilitation.

Outcomes

Our OOPE has increased our confidence in working independently, further developed our leadership and team working skills. We gained a better understanding of rural healthcare delivery from a different perspective.

Keywords: GP training, OOPE, Rural General Practice

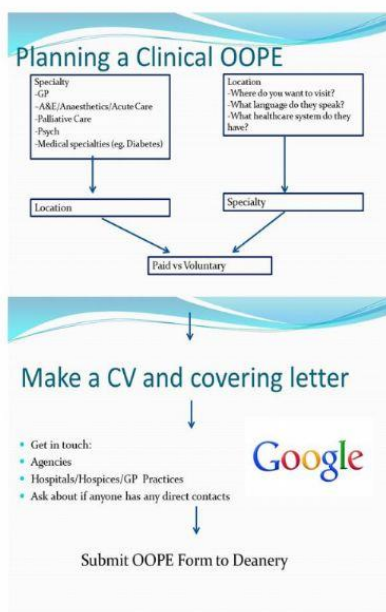

Partnership with Southlink Health

Postcard from NZ

Figure 1-Clinical OOPE Planning

OOPE

GP Rural Track Training: Out of Programme Experience (New Zealand)

Dr Christopher Mulholland, Dr Kate Dixon

Background
The new GP training in the rural GP track programme based in the Western Isles, Scotland, in August 2014 is now completed. The hospital part of our training, and embedded in our Out of Programme Experience (OPE) prior to the remaining GP based training.

The aim of the OPE in the rural track programme is to enable GP trainees to extend their training and enhance their skills and competencies in areas that are difficult to achieve within the standard three-year programme.

This OPE is a month (On our rural track training programme) during our 3rd year of a 4 year programme.

Exit OPE Health
East Dunbartonshire based in Polmont, Otago, South Island, New Zealand. Led by Practice Manager-Cathryn Mackay & Professor of General Practice- Prof. Campbell Murdoch.

Practice Demographics
Approx 3000 (rural) +80% Over 55s, 20% Under 16, Farming, Being, Gold mining.

Our Role
To work as GP Registrar under supervision of Prof. Murdoch between Polmont and Walkabout practices. 8 clinical sessions per week.

Rural Healthcare Challenges
- Important to appreciate the differences of rural vs urban General Practice
- NZ also have similar recruitment and retention problems, particularly rural.
- Geographical issues - distance to secondary care, patient access to GP sites etc.
- Service provision - implications on specialty services locally eg radiology, mental health etc.

Work/Life Balance
From our location in Polmont, we were able to explore the central Otago, Dunedin, Wanaka, Mount Cook, Cairnui all within a 2 hour drive. Good pace of life. Longer appointment times. Fantastic team attitude.

Differences between New Zealand and UK General Practice

UK	NZ
Consultation	Consultation cost between \$30-40 (free for under 5s)
10 minute appointments	15 minute appointments
Free Prescriptions (Scotland +Wales)	Script cost \$5 (at pharmacist)
Free A&E/Casualty care	Accident Claims Compensation scheme -Reduced initial consultation -Free accident/injury related further appts -Case manager to link with employer/physio/private specialist/care services for rehabilitation
Free Secondary Care	Free Secondary Care
Free Older Persons Health/Chronic Disease care	Care Plus scheme-permits 4 free consultations/year (GP/Practice selected)
Free Palliative Care	Free Palliative Care

Maori Health
Maori are the indigenous population of New Zealand and make up about 15% of the population. Yet there are inequalities of health in Maori populations. They have the poorest health of any New Zealand group, higher rates of CVD, diabetes, obesity, mortality than non-Maori. Most are often linked to historical social economic factors. There is ongoing research into health disparities for Maori in New Zealand. Maori are entitled to free cardiovascular screening checks after age of 35. This is a great opportunity for responsible health promotion such as celebrating Māori being about healthy Maori, bringing up smoking cessation, identifying patients, about prostate checks etc.

What did we learn?
Fulfilled our passion for rural General Practice. Truly enhanced our clinical knowledge. Improved our confidence in working independently. Developed our leadership skills with a practice team, undertaking educational sessions and multidisciplinary team working. For the future sustainability of the workforce, we feel it is important to promote rural health and allow flow of professionals between countries.

Table 2: Differences between NZ and UK General Practice

UK	NZ
Free Consultations	Consultation cost between \$30-40 (free for under 5s)
10 minute appointments	15 minute appointments
Free Prescriptions (Scotland +Wales)	Script cost \$5 (at pharmacist)
Free A&E/Casualty care	Accident Claims Compensation scheme -Reduced initial consultation -Free accident/injury related further appts -Case manager to link with employer/physio/private specialist/care services for rehabilitation
Free Secondary Care	Free Secondary Care
Free Older Persons Health/Chronic Disease care	Care Plus scheme-permits 4 free consultations/year (GP/Practice selected)

Academic Leadership Development (ALD) Program at College of Medicine- Jeddah; King Saud bin Abdulaziz University for Health Sciences

Saad Abdulrahman Alghamdi, Wesam Abuznahdah, Almoutaz Alkhier Ahmed
National Guard Health Affairs / WR - Saudi Arabia

INTRODUCTION:

The new Medical College in Jeddah (COM-J) – a branch of King Saud bin Abdulaziz University for Health Sciences – is currently confronting many challenges, accelerating the need for effective academic leaders. Unfortunately, little is known about how the competency of academic leaders underpins effective performance or how leaders might be aided in acquiring competency. This environment has driven authorities at COM-J to be proactive in the establishment of the Academic Leadership Development (ALD) program for current and potential future academic leaders.

OBJECTIVES:

To assess the perception of academic leaders on the importance of capability, different approaches and criterion for judging effective performance

METHODOLOGY:

A cross-sectional online survey was conducted with 47 academic leaders at COM-J. In addition to demographic data, information on academic leaders' perception of the importance of three datasets (capabilities, approaches and judging criteria) was collected using a five-point Likert scale (1 – low to 5 – high). The project team and experts in the field of leadership development assessed the face validity of the survey instrument. The reliability of the survey instrument was calculated; Cronbach's coefficient alpha was 0.97 (a high value).

Program Model:

We have adopted a model of academic leadership development that has already been tested in several large-scale studies of effective leadership in higher education.

Results

The response rate was 100% (47), and the academic leaders perceived that a combination of emotional intelligence (both personal and interpersonal), cognitive capabilities and a set of relevant skills and knowledge are necessary for effective performance as an academic leader at COM-J.

CONCLUSION:

We produced a model for an ALD program at COM-J with the following attributes:

- A set of capabilities and competencies for effective leadership
- A set of quality checkpoints (criterion for judging effective performance)

Keywords: Education, leadership

Figure 1: Model of Academic Leadership Development

Emotional Intelligence in Medical Education

Fusun Artiran Igde, M. Kursat Sahin

Department of Family Medicine, Ondokuz Mayıs University, Samsun Turkey

Background&AIM: Emotional intelligence involves the perception, processing, regulation and management of emotions. In this study we aimed to examine emotional intelligence levels according to the gender, different class of faculty among students at Ondokuz Mayıs University Faculty of Medicine in Samsun-Turkey.

MATERIALS-METHODS: This cross-sectional study carried out in first three years students of medicine between September 2014- May 2015. Turkish adapted form of the revised Schutte emotional intelligence scale and sociodemographic questionnaire was used and data was assessed with the SPSS program.

RESULTS: 532 students (52.5% female, 47.5% male), from first three years of medical faculty participated in the study. 237 (44.5%) students were from the first class, while 144 (27.1%) and 151 (28.4%) of them were class 2 and 3 respectively. The mean age was 20.63 ± 2.73 years. The majority (50%) of the group were in the age range 20–21 years with the remaining 26% being in the age range 18–19 years. Total emotional intelligence test scores were significantly different according to gender; 124.85 ± 6.45 for females and 126.68 ± 8.35 for males ($p: 0.005$) surprisingly females had lower scores than males. Analysis of difference by groups using analysis of variance showed no differences among three classes for emotional intelligence. ($F=2.69$, $p=0.69$)

CONCLUSION: Medicine is an emotionally demanding practice and medical education aims to develop doctors with a wide-ranging of skills including emotionally responsive. Medical schools should update their curriculum promoting emotional intelligence capability.

Changes in Empathy during Medical Education

Fusun Artiran Igde, M. Kursat Sahin

Department of Family Medicine, Ondokuz Mayıs University, Samsun Turkey

Background&AIM: Empathy is a key element of patient– physician communication; it is relevant to and positively influences patients' health.

In this study we aimed to investigate changes in students' empathy levels during medical school at Ondokuz Mayıs University Faculty of Medicine in Samsun-Turkey.

MATERIALS-METHODS: This cross-sectional study carried out in first three years students of medicine during September 2014 to May 2015. Turkish adapted form of the student version of Jefferson empathy scale and sociodemographic questionnaire was used and data was assessed with the SPSS program.

RESULTS: 532 students (52.5% female, 47.5% male), from first three years of medical faculty participated in the study. 237 (44.5%) students were from the first class, while 144 (27.1%) and 151 (28.4%) of them were class 2 and 3 respectively. The mean age was 20.63 years, standard deviation 2.73 years. Significant differences in the empathy scores were observed among first three years in medical school (Table) but not between genders.

CONCLUSION: Empathy is crucial for physicians' professionalism and most studies on the patient-physician relationship express that this attitude has a key role in improving clinical outcomes but unfortunately the decrease in empathy during medical education is obvious.

P-0951

Family medicine residents' and family doctors' perspective regarding implementation of part time vocational training scheme

Mehmet Akman¹, Ç. Batuhan Taşcı², Goncagül Arslan², Ayşegül Özyurt², Merve Karaoğlu²

¹Department of Family Medicine, Marmara University, Istanbul, Turkey

²Medical student, Marmara University, Istanbul Turkey

Background & AIM: Less than 10% of current primary care doctors in Turkey finished vocational training (VT). In order to increase this percent, Ministry of Health implemented a part time VT scheme for family doctors (FDs). However this scheme in its current form considered to be unacceptable and unfair among family medicine specialists and residents. This research aims to explore perspectives of FDs' and family medicine residents' regarding this implementation.

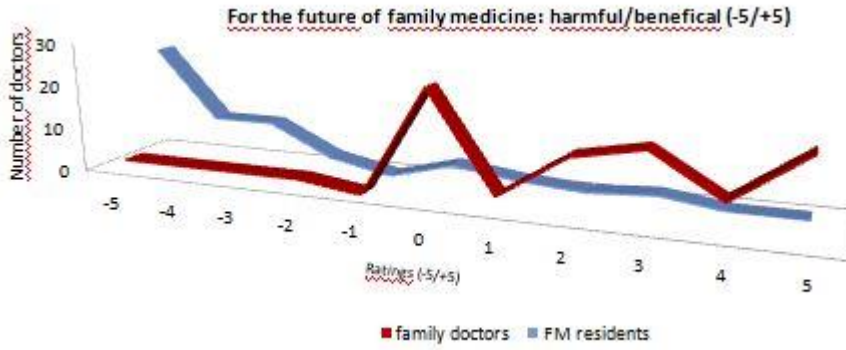

METHOD: A pre-prepared questionnaires were filled by FDs (22 questions) and family medicine residents (15 questions). The data collection was carried out in primary care centres of Üsküdar district, and three teaching hospitals on Asian side of Istanbul. In total 90 FDs and 58 residents gave consent to participate.

RESULTS: 94.1% of family doctors do not think that part time VT would be beneficial for primary care. 92.2% of FDs think that their absence from their current work place will cause serious problems if ever they go for training in a teaching hospital. 71.4% of them believe that their patient list will be affected negatively. 56.7% of FDs under median age (41) thinking about participating half time training, whereas same percent is 26,3% among the family doctors above the median age (41) ($p < 0,05$). 98,3% of the residents concerned about inequalities related to compulsory service after completion of VT. 94.8% of the residents believe that this implementation is unfair and 82.8% of the residents believe that there will be a difference in quality between full time and part time training models.

CONCLUSION: FDs and family medicine residents believe that part time part time VT will not improve the quality of primary care services. According to participants it is not feasible to participate VT while serving for assigned patient list simultaneously. Several opportunities for promoting part time VT cause a perception of injustice among residents.

Primary Care Family Physicians 1st Stage Orientation Training

Özlem Aynaoglu¹, Çağla Arslan¹, Mustafa Kaya¹, Özlem Yiğitbaşıoğlu¹, Alev Yücel¹, Sevinç Boz², Selahattin Taşoğlu¹

¹Public Health Institution, Ankara, Turkey

²Istanbul Provincial Directorate of Health

AIM: "Primary Care Family Physician 1st Stage Orientation Trainings" are organized for 6 days in order to raise awareness and provide a standardization for the physicians that work at first step primary health care services either during their whole professional career or at a certain period. In this way, it is aimed to equip the physicians who will work at first step primary care health services with the necessary knowledge, attitude and skills required for this specialty.

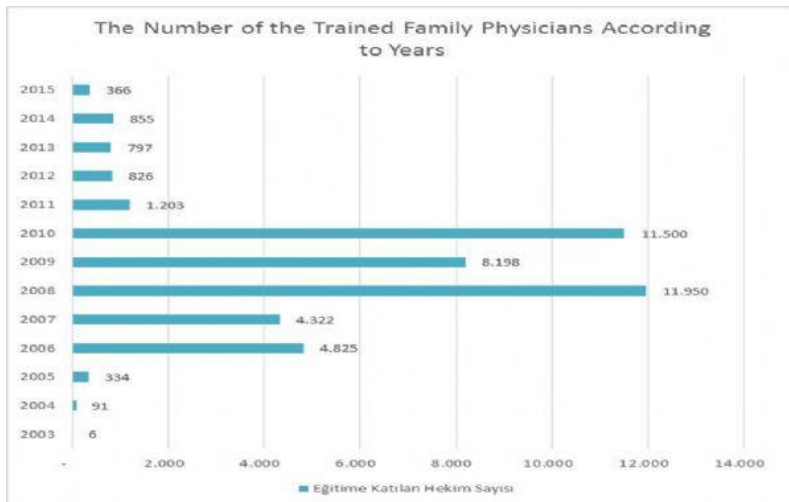

METHOD: Orientation Trainings comprised of 1st stage and 2nd stage trainings. 1st stage Orientation trainings last 6 days. There are 3 or 5 trainers and they co-ordinate the training of a group of 18-25 trainees. Training content consists of interactive methods such as case study based learning, role-playing and reflection and skill guidelines. The content of the training was revised in September 2014 and the duration was updated to 6 days which was 10 days before. Updates will continue towards the needs. Before start of the course an assessment test is held. At the end of each day a questionnaire with five point Likert scale is given. At the end of the course together with a questionnaire that evaluates the whole course period, a final exam is held. The second stage is given by a way of distant learning.

RESULTS: The Number of the family physicians who took 1st Stage Orientation Trainings up to May 2015 is 45.273. The Number of the Family Physicians who are waiting for 1st Stage Orientation Trainings up to May 2015 is 441.

CONCLUSION: Together with the primary care family physician practice individual-centered care approach has emerged and the job-description of physicians is determined as protection, diagnosis, treatment, rehabilitation and consultancy. Standardization and awareness has been set with the support of these adaptation and orientation trainings.

Vitamin D:the updates,primary health care aproach

Dusan Popovic, Kenan Katana

Primary Health Center Podgorica, Montenegro

THE AIM: For a long time the importance to measure the level of vitamin D in the serum was ignored. The fact is that vitamin D deficiency in 50-70% cases is unrecognized by doctors at all levels of health care. The deficit of vitamin D and its associated disease is not a rare occurrence, like many serious problems of the modern era. The aim of this review is to remind us all a little on the current knowledge, to be aware of the news in the treatment of diseases and what is most important-preventing Vitamin D deficiency-dependent diseases in primary-level health. The emphasis is on the need for better recognition of the symptoms and risk groups, for detecting the risk of disease before its occurrence by a doctor in PHC.

METHOD: This study represents a sublimates of the latest researches and prevention measures, the physiology of vitamin D with emphasis on high-risk groups and lifestyles that can lead to serious disease. This type of review will be a good reminder for the daily work in clinics. The principle consists in identifying people of high-risk groups, and to measure the concentration of vitamin D serum, depending on the value the protocol will be given based on the amount of the supplement which is necessary for prophylactic and therapeutic treatments.

CONCLUSION: According to knowledge, the adequate intake of vitamin D is very important during the childbearing age (rickets), osteoporosis, also in children who have problems with the bronchi, multiple sclerosis, while some authors claim that this is important even in cancer prevention, based directly on the immune system. The cooperation with PHC laboratories is very important for providing this type of screening in PHC level and to improve the health system.

Primary School Teachers' Knowledge On Dyslexia, In Turkey

Hamit Sırrı Keten¹, Oğuz Işık², Hakan Öney³, Özgür Ersoy⁴, Yaşar Koşar², Soner Ölmez⁵, Mustafa Çelik²

¹Department of Family Medicine, Kurtul Family Health Center, Kahramanmaraş, Turkey

²Department of Family Medicine, Medical Faculty, Kahramanmaraş Sutcu Imam University, Kahramanmaraş, Turkey

³Faculty of Arts and Humanities, Arts, Sciences & Technology University in Lebanon, Beirut, Lebanon

⁴Department of Public Health, Medical Faculty, Cukurova University, Adana, Turkey

⁵Department of Family Medicine, Samsat Family Health Center, Adıyaman, Turkey

BACKGROUND: This study aims to determine primary school teachers' knowledge about dyslexia among Turkish students.

METHOD: This survey study conducted in 64 primary schools in Kahramanmaraş, Turkey between 01.02.2015 and 01.04.2015. A total of 617 primary school teachers participated in the study. A questionnaire comprising questions regarding socio-demographic and professional features, their knowledge about dyslexia were applied to teacher through a face to face interview. The level of knowledge was assessed by 20 questions and 20 points for each.

RESULTS: Out of 617 participants 330 (53.5%) were male and 287 (46.5%) were female, while the mean age was 40.81±9.76 (min=22, max=63) years. Regarding answers to "Have you ever heard the term dyslexia?" 412 (66.2%) participants answered yes, while interestingly 205 (33.2%) participants answered no. Only 52 teachers (8.4%) had received special training in dyslexia, while 565 (91.6%) not. The average knowledge score of participants was 6.58±3.70 (min = 0, max = 15) point. A majority of participants (n:456, 73.9%) were agreed on definition of dyslexia as "specific learning disorder". Of participants 272 (44.1%) agreed the wrong statement of "The use of colorful objects and colored covers might be helpful in dyslexia", while 315 (51.1%) stated that they had no idea about this suggestion. Almost half of participants (n:289, 46.8%) agreed the wrong statement of "Making eye-tracking exercise is effective in treating challenges of Dyslexia", while 295 (47.8%) had no idea about this suggestion.

CONCLUSION: Obtained findings suggest that primary school teachers seriously suffer from lack of knowledge and misinformation about dyslexia. This possibly caused by low number of teachers trained about dyslexia. Joint projects by Ministry of Education and Ministry of Health, and efficient use of media will be helpful in fight against dyslexia.

Keywords: Dyslexia, Reading disorder, Learning disorder, Teachers, Primary school

Social Problem Solving and Coping Skills of Medical Students

Emel Yigit¹, Sevgi Ozcan¹, Gulsah Seydaoglu²

¹Department of Family Medicine, Çukurova University, Adana, Turkey

²Department of Medical Education and Biostatistics, Çukurova University, Adana, Turkey

AIM: Social problem solving has been defined as the set of instrumental, cognitive-behavioural skills necessary for adaptation in everyday life. The aim of this study is to determine medical students' social problem solving and coping skills.

METHODS: In this correlational descriptive study, data were gathered from 457 medical students (206 female and 251 male), selected through 1 (n=214), 4(n=142), and 6 (n= 101) grade. Social Problem Solving Inventory (SPSI) and Social Problem Coping Behaviours Inventory (SPCB) were used.

RESULTS: Data analyses showed that social problem solving and coping skills of medical students were around the average level. The most frequent problem solving approaches were positive and rational styles. The most frequent activities when they face a social problem were meeting with friends (87.1%), meeting with special person (85.4 %), sleeping (82.6%), meeting with family members (81.6%), and eating (79.8%). Those whose mother education is high, whose family income is high, who have chronic illness, who have lost year, and men have a significantly high score of addictive coping behaviours (such as playing chance games, smoking, using alcohol and drug). There was a positive relationship between total scores of SPSI and SPCB ($r= 0.40$, $p< 0.05$). Immature social problem solving ability has increased the risk of unfavourable behaviours by 3.1 fold (OR: 3.1, 95 % CI: 2.2 -4.7, $p= 0.0001$).

CONCLUSIONS: The results of our study demonstrate that social problem solving ability is significantly correlated with coping behaviours and may predict it. Medical students who are the doctors and the role models of the future need to develop their social problem solving skills in addition to clinical problem solving skills.

Attitudes, Behaviors and Knowledge of Family Physicians Regarding Rational Drug Use

Hande Perk Gürün, Dilşad Save, Seyhan Hıdıroğlu, Belma Çalışkan

Department of Public Health, Marmara University, İstanbul, Turkey

Background&AIM: WHO has described rational drug use in 1985 in Nairobi. Irrational drug use is still a problem for developing countries like Turkey. The aim of this study is to evaluate attitudes, knowledge and behaviors of family physicians regarding rational drug use. METHOD: The study was conducted among family physicians who agreed to attend study, between May and June 2015, in İstanbul. RESULTS: In our study 75 of the physicians was general practitioner and 14 was professional family physicians. The mean of daily patient exam was 55. %80.7 was attend an after graduate education and %51.1 was attend a rational drug use education. To apply a guideline rate was %94.4. Results: In our study 75 of the physicians was general practitioner and 14 was professional family physicians. %80.7 was attend an after graduate education and %51.1 was attend a rational drug use education. To apply a guideline rate was %94.4. The most frequent applying guide is Vademecum (%64). Drug using knowledge is medium and higher among all physicians (indications, pharmacological properties, contraindication and etc.). Physicians frequently ask drug allergy, liver and kidney disease, chronic disease, pregnancy and age for history but they ask gender rarely. According to %48 of the family physicians (43), giving information about drugs not enough for patients. Physicians rarely say efficacy mechanism(%6.7), price(%3.4), interactions with food and drug(%8) to patients. %40.4 of physicians control if patients understand how they use the drug. Using a prescription guide is statistical significant among physicians attend and not attend a rational drug use education($p<0.02$). Reporting side effect is statistical significant among physicians attend and not attend a rational drug use education($p<0.001$).

CONCLUSION: it was shown that family physicians do not fully apply the principles of rational drug use while

managing their patients. This problem might be solved partly by continuous education of the physicians about this issue.

Keywords: rational drug use, family physician, knowledge

A Community Based “Primary Care Internship Program”

Senem Buğdaycı¹, Pemra Ünalın¹, Işıl Maral², Serap Çifçili¹

¹Department of Family Medicine, Marmara University, Istanbul, Turkey

²Department of Public Health, Marmara University, Istanbul, Turkey

Background&AIM:

In this study we aimed to share the principles, goals and education methods used in the “Toplum Sağlığı Bloğu”. That module which was ran for the first time in the 2014-2015 school year for the Marmara University School of Medicine(MUSM) interns who will end their internship with a board-like exam for medical specialties(TUS). In addition, feedbacks given by the module attendants and teachers will be shared.

METHODS: A 17-week “Community Health” module was implemented to the curriculum of MUSM in 2014. After a multi-departmental planning, the block started with the essentials of public health, family medicine, and an introduction to research in primary care. The researches were planned and carried out in the community with supervisors. Public health lectures and practices, ambulatory discussions about most common clinical problems in family medicine, lectures in forensic medicine and obstetrics, including family planning and counselling in reproductive health were given. The module motivated self-directed learning with free study times. The expectations and the feedback were surveyed. Deep interviews were conducted with faculty members and GPs who took place in this program. Thematic analysis was performed.

RESULTS: Of the 110 participants 57 were male, 17 were positive about working in primary care and only 21 would choose the module if it was elective. Attendants rating the module higher, would participate if the module were elective ($p=0,000$; $t=5,367$). Attendance would also increase if there were no TUS examination ($n=47$; $p=0,000$; $t=3,609$). Studying for TUS was the most remarkable one common among the expectations.

CONCLUSION: It was seen that interns are not familiar with the concept of community oriented health care and their main concern was to have more study time for TUS. So a shorter but more effective and student centered program should be planned.

Number of attendants who would choose the module if it were elective.

Graphic 2

47 attendants, who said that they would choose the "Toplum Sagligi Blogu" module if there were no TUS examination gave an average of 5,53 out of 10 points to the module. Attendants, who wouldn't choose the module (n=63) gave the module 4,11 out of 10 points on average. The difference was statistically significant (Student's t-test: p=0,000; t=3,609).

Family Physicians Continuing Professional Development Training (AHUZEM)

Çağla Arslan, Özlem Aynaoglu, Özlem Yiğitbaşıoğlu, Selahattin Taşoğlu, Mustafa Kaya, Alev Yücel, Irfan Şencan
Public Health Institution of Turkey

AIM: Family Medicine Continuing Professional Development Training is given to Physicians working in primary care to improve and update their professional knowledge.

METHOD: Family Medicine Continuing Professional Development Trainings was started on 01.12.2012 as a way of distance learning. Training is provided by the Distance Education Platform continuously updated modules. There are a total of 166 courses located in 15 modules in the system. Training material has been prepared by academics who specialize in the field of educational research in universities and hospitals. Academic personnel make their course presentations towards specified content with video recordings in Distance Learning Platform, measurements and assessments are carried out via implementing pre-tests and final tests before and after courses. To successfully complete the training, trainees must get at least 50% of the final test correct. Duration of training is planned to be at least 1 year.

RESULTS: A total number of 21.686 physicians have attended to the AHUZEM. 19.885 of these are Family Physicians, 971 are Family Medicine specialists and the 830 of these are Public Health Directorate Physicians..

CONCLUSION: At the end of 2010 in Turkey, the implementation of family medicine was completed and with transition to family medicine practice, transitional period trainings have begun in Turkey. Transitional period trainings in our country are divided into two main phases. Under Public Health Institution of Turkey, trainings have begun with 2nd Phase Trainings via Distance Learning Platform at the end of 2012 and constitute an important place among e-Learning applications. To ensure the improvement of service quality standards, family practitioners are obliged to attend at least 80% of the first and second stages of education and other training, determined by the Public Health Institution of Turkey.

⁴department of family medicine, başkent university, ankara, turkey

Vasco da Gamma Movement (VdGM) is a working group for young general practitioners (GP). "Young" term includes GP trainees and specialist GPs in their five years. Turkish VdGM team organised a session in a national congress in September'14 in Antalya and conducted a national survey to identify the perspective of its participants.

During a one hour session, team explained the aim of VdGM and its activities. In the end participants were asked to be volunteer to fill the feedback forms about that session.

The feedback forms were consisted of seven 1 to 5 Likert scaled item (1 was "I totally disagree" and 5 was "I certainly agree.") and an open ended item in which participants could give their opinions and suggestions briefly. Mean points for all questiones were calculated and answers for the last item was identified.

All of 32 participants filled the forms. The highest mean point was given to item questioning the content and the lowest mean point was given to questioning the impact of this session to the future career.

The last item was filled by nine participants. Three participants thanked to VdGM team for organising that session. One participant applied for a membership and two participant for the next VdGM exchange programme. One participant complained about the membership criteria which was to be "young" and one participant suggested to add a new criteria which allows not specialist GPs to become a member. One participant criticized the session not to have a formal language and evidence based background.

Session was found to be paralel to to the topic and its content. Language of VdGM sessions among Europe might not be familiar to some Turkish participants. Turkish team could offer to VdGM executive group to discuss about membership criteria.

²CS Don Paulino García Donas, Alcalá de Guadaíra. AGS Sevilla-Sur, Andalussia, Spain.

³CS Utrera Sur, Utrera. AGS Sevilla-Sur, Andalussia, Spain

⁴CS Doña Mercedes, Dos Hermanas. AGS Sevilla-Sur, Andalussia, Spain.

⁵CS Estepa, Estepa. AGS Osuna, Andalussia, Spain

⁶Emergency Department, Valme University Hospital, Sevilla. AGS Sevilla-Sur, Andalussia, Spain

⁷Internal Medicina Department, Valme University Hospital, Sevilla. AGS Sevilla-Sur, Andalucia, Spain

Male aged 20 years old, no relevant medical history. Consults of painful swelling in left side of the neck two days ago. It appeared while doing workout at the gym. No other symptoms then nor now.

Exploration: Acceptable general condition. Well hydrated and perfused. Normocoloured. Eupneic. Afebrile.

Normal ENT area. Cardiopulmonary auscultation and abdominal palpation without findings. In his neck he has left supraclavicular gummy indurated tumor that seems to be adhered to deeper tissue. Size 1x2cm. Aches at palpation. Normal cervical movement, painful muscle palpation. No palpable adenopathies.

Clinical judgement: Left cervical protuberance: Adenopathy vs Muscle tear with hematoma.

Initial treatment: Ibuprofen 600mg/8h. Review in one week if no improvement.

Evolution: a week later, the mass has grown, so we decide to perform an ultrasonography at our office: we see a rounded image measured 3.8x2.9cm, heterogeneous and hypoecogenic. We then request general blood test including Cytomegalovirus and Epstein-Baar serology and a chest Xray that appear to be normal. Our patient is referred to the Internal Medicine Department, where a new ultrasonography reveals left supraclavicular and jugular adenopathic conglomerates. The biopsy of the adenopathies show a pattern consistent with Non-Hodgkin lymphoma (nodular sclerosis).

Finally he is referred to Hematology to finish extension study and treatment.

Final Diagnosis: Non-Hodgkin Lymphoma.

Conclusion (and contribution to family doctors): The challenge of Family Medicine is identifying that need to be referred to a second assistance level due to a malignant suspicion. Ultrasonography becomes a new diagnostic eye and ease diagnostic and therapeutic approach, so we can refer a patient sooner and more properly to a certain specialist. We so consider education in ultrasonography very important for new specialists.

Evaluation of Family Medicine Residents' Competency in Ophthalmology Patient Care at Primary Health Care Settings

Hilal Biten¹, Rabia Kahveci², Dilek Çalışkan Özçelik², Esra Meltem Koç³, İrfan Şencan², İsmail Kasım², Adem Özkara²

¹Ankara Numune Training and Research Hospital, Ankara, Turkey

²Department of Family Medicine, Ankara Numune Training and Research Hospital, Ankara, Turkey

³General Directorate of Health Researchs, Ministry of Health, Turkey

OBJECTIVES: The aim of this study is to obtain the thoughts, knowledge levels and training needs' of the family medicine residents in Ankara about ophthalmology in Ankara. Also with this study we aimed to raise awareness on this issue and guide the studies that aimed to promote standart care for ophthalmology patients.

METHOD: Between 01/04/2015-01/05/2015 we applied a questionnaire, developed by researchers to the family medicine residents who were working at a training and research/ university hospital in Ankara. We reached to the 200 family medicine residents to join to the survey but 196 of them completed the questionnaire. Data analysis was performed with SPSS 21.0 for Windows application.

RESULTS: Only 12,8% of the residents think that the ophthalmology training given in the medicine faculty is enough, but 54,1% of them disagree and 33,2% of them partially agree. It's found that the most common cause of inadequate training in medical faculty is lack of practice. 9,5% of the family physicians agree that the ophthalmology training given during the family medicine specialization training is enough but 67,5 % of them disagree and 20,5 % of them partially agree. Residents think that ophthalmology education in family medicine training is not sufficient because Ophthalmology rotation is optional in the curriculum.

CONCLUSION: It has been advised that current curriculum of family medicine training should be revised according to the needs of primary health care profile. The curriculum should involve topics oriented for common symptoms and signs of eye disorders and aid to raise knowledge and skills in primary health care settings.

Knowledge of Tuberculosis Among Health Higher School Students'

Vasfiye Bayram Değer¹, Betül Battaloğlu Inanç², Sema Çifçi¹

¹Mardin Artuklu University, Health Higher School, Mardin.

²Muğla Sıtkı Koçman University, Faculty of Medicine, Family Medicine Department

AIM: Aimed to determine students' tuberculosis (tbc) knowledge level and effectiveness of education. **MATERIAL-METHOD:** A questionnaire form which consisting of 10 questions was applied to Mardin Artuklu University Health School students in 18-19 April 2013 to determine their level of knowledge before and after a two-day training for tuberculosis.

RESULTS: 196 students' data were included. After training, most common right answers rate were initially 22.4% whose vaccinated necessary, 13.7% whose control after tbc patient close contact and 13.3% what was the tbc illness agent were learned

by students. After training, the way of diagnosis to patient was remained basically same, right answers rate decreased 1.5% which organs influence with tbc, 0.5% increased right answer rate for risk of spread tbc but remained lowest among the other right answers. Tbc disease agent is a bacteria, smudge with airway is agreed by the students' ($p=0.0001$). Whose risk of developing tbc and how was treat patients was learned increasingly by students after training ($p=0.0001$). Before training, awareness of the spread of tbc to lung, lymph node and brain membrane was known and was found significantly ($p=0.0001$). After training, vaccination of infants ($p<0.001$), and most common symptom of pulmonary tuberculosis ($p=0.0001$) is shown statistically significant. After training was thought to diagnosed tbc with skin test was statistically significant ($p <0.001$). Training was not change student's knowledge and approach this two points; whose control was necessary with tbc close contact persons' ($p=0.065$) and what was the directly observed treatment ($p=0.058$).

DISCUSSION: Although, our students' knowledge about tuberculosis is enough but continuing education programs, and updating of information must provide.

Sights of family medicine residents about training in practise

Sezin Yılmaz, Mehmet Karacagil, Dilek Güldal, Tolga Günvar
Dokuz Eylül University, Family Medicine, İzmir

BACKGROUND and OBJECTIVE: Training in practice is indispensable part of specialization training and must be performed in primary care under the supervision of the family medicine trainers. Although specialization training is given in our country for more than 30 years, the legal regulations related to training in practise is the product of the last two years. In our study, it is aimed to investigate how this new form of training is perceived by the family medicine trainees.

METHOD: A cross-sectional study is conducted among the residents of family medicine. A questionnaire is distributed to trainees through family physicians mail groups. Data were entered into SPSS 15.0 programme and the chi-square and t tests were performed besides the descriptive analysis.
